A complete set of mutually conjugate GROUP elements. Each element in a GROUP belongs to exactly one class, and the IDENTITY ELEMENT ($I = 1$) is always in its own class. The ORDERS of all classes must be integral FACTORS of the ORDER of the GROUP. From the last two statements, a GROUP of PRIME order has one class for each element. More generally, in an ABELIAN GROUP, each element is in a conjugacy class by itself.

Two operations belong to the same class when one may be replaced by the other in a new COORDINATE SYSTEM which is accessible by a symmetry operation (Cotton 1990, p. 52). These sets correspond directly to the sets of equivalent operations.

To see how to compute conjugacy classes, consider the FINITE GROUP D_3, which has the following MULTIPLICATION TABLE.

D_3	1	A	B	C	D	E
1	1	A	B	C	D	E
A	A	1	D	E	B	C
B	B	E	1	D	C	A
C	C	D	E	1	A	B
D	D	C	A	B	E	1
E	E	B	C	A	1	D

{1} is always in a conjugacy class of its own. To find another conjugacy class take some element, say A, and find the results of all similarity transformations $X^{-1}AX = X^{-1}(AX)$ on A. For example, for $X = A$, the product of A by A can be read of as the element at the intersection of the row containing A (the first multiplicand) with the column containing A (the second multiplicand), giving $A^{-1}AA = A^{-1}1$. Now, we want to find Z where $A^{-1}1 = Z$, so pre-multiply both sides by A to obtain $(AA^{-1})1 = 1 = AZ$, so Z is the element whose column intersects row A in 1, i.e., A. Thus, $A^{-1}AA = A$. Similarly, $B^{-1}AB = C$, and continuing the process for all elements gives

$$A^{-1}AA = A \tag{1}$$

$$B^{-1}AB = C \tag{2}$$

$$C^{-1}AC = B \tag{3}$$

$$D^{-1}AD = C \tag{4}$$

$$E^{-1}AE = B \tag{5}$$

The possible outcomes are A, B, or C, so $\{A, B, C\}$ forms a conjugacy class. To find the next conjugacy class, take one of the elements not belonging to an existing class, say D. Applying a similarity transformation gives

$$A^{-1}DA = E \tag{6}$$

$$B^{-1}DB = D, \tag{7}$$

so we need proceed no further since D and E both appear, meaning $\{D, E\}$ form a conjugacy class and we have exhausted all elements of the group.

Let G be a FINITE GROUP of ORDER $|G|$, and let s be the number of conjugacy classes of G. If $|G|$ is ODD, then

$$|G| \equiv s \pmod{16}$$

(Burnside 1955, p. 295). Furthermore, if every PRIME p_i DIVIDING $|G|$ satisfies $p_i \equiv 1 \pmod 4$, then

$$|G| \equiv s \pmod{32}$$

(Burnside 1955, p. 320). Poonen (1995) showed that if every PRIME p_i DIVIDING $|G|$ satisfies $p_i \equiv 1 \pmod m$ for $m \geq 2$, then

$$|G| \equiv s \pmod{2m^2}.$$

Conjugate

COMPLEX CONJUGATE, CONJUGATE ELEMENT, CONJUGATE GRADIENT METHOD, CONJUGATE MATRIX, CONJUGATE POINTS, CONJUGATE SUBGROUP, CONJUGATION MOVE

Conjugate Element

Given a GROUP with elements A and X, there must be an element B which is a SIMILARITY TRANSFORMATION of A, $B = X^{-1}AX$ so A and B are conjugate with respect to X. Conjugate elements have the following properties:

1. Every element is conjugate with itself.
2. If A is conjugate with B with respect to X, then B is conjugate to A with respect to X.
3. If A is conjugate with B and C, then B and C are conjugate with each other.

See also CONJUGACY CLASS, CONJUGATE SUBGROUP

Conjugate Gradient Method

An ALGORITHM for finding the nearest LOCAL MINIMUM of a function of n variables which presupposes that the GRADIENT of the function can be computed. It uses conjugate directions instead of the local GRADIENT for going downhill. If the vicinity of the MINIMUM has the shape of a long, narrow valley, the minimum is reached in far fewer steps than would be the case using the STEEPEST DESCENT METHOD.

See also GRADIENT, LOCAL MINIMUM, MINIMUM, STEEPEST DESCENT METHOD

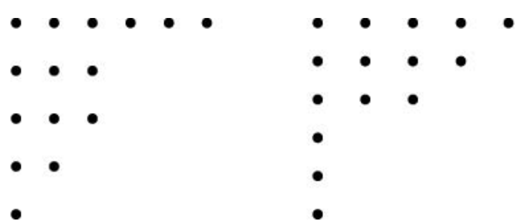
Conjugate Matrix



The matrix $\bar{\mathbf{A}}$ obtained from a given matrix A by taking the COMPLEX CONJUGATE of each element of A (Courant and Hilbert 1989, p. 9). The notation A^* is sometimes also used, which can lead to confusion since this symbol is also used to denote the ADJOINT MATRIX.

See also ADJOINT MATRIX, COMPLEX CONJUGATE

Conjugate Partition

Pairs of partitions for a single number whose FERRERS DIAGRAMS transform into each other when reflected about the line $y = -x$, with the coordinates of the upper left dot taken as (0, 0), are called conjugate (or transpose) partitions. For example, the conjugate partitions illustrated above correspond to the partitions $6+3+3+2+1$ and $5+4+3+1+1+1$ of 15. A partition that is conjugate to itself is said to be a SELF-CONJUGATE PARTITION.
The conjugate partition of a given partition l can be implemented in *Mathematica* as follows.

```
ConjugatePartition[l_List] :=
 Module[{i, r = Reverse[l], n = Length[l]},
  Table[n + 1 − Position[r, _?(# > = i &),
   Infinity, 1][[1, 1]],  {i, l[[1]]}
   ] ]
```

A similar implementation is given as TransposePartition[l] in the *Mathematica* add-on package DiscreteMath`Combinatorica` (which can be loaded with the command << DiscreteMath`).

Conjugate Permutation

INVERSE PERMUTATION

Conjugate Points

HARMONIC CONJUGATE POINTS, INVERSE POINTS, ISOGONAL CONJUGATE, ISOTOMIC CONJUGATE POINT

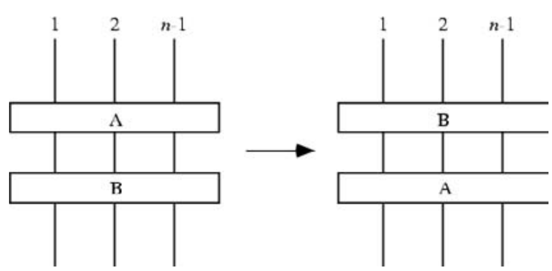
Conjugate Subgroup

A SUBGROUP H of an original GROUP G has elements h_i. Let x be a fixed element of the original GROUP G which is not a member of H. Then the transformation xh_ix^{-1}, $(i = 1, 2, \ldots)$ generates the so-called conjugate subgroup xHx^{-1}. If, for all x, $xHx^{-1} = H$, then H is a SELF-CONJUGATE (also called "invariant" or "normal") SUBGROUP.

All SUBGROUPS of an ABELIAN GROUP are SELF-CONJUGATE.

See also SELF-CONJUGATE SUBGROUP, SUBGROUP, SYLOW THEOREMS

Conjugate Transpose Matrix



ADJOINT MATRIX

Conjugation

The process of taking a COMPLEX CONJUGATE of a COMPLEX NUMBER, COMPLEX MATRIX, etc., or of performing a CONJUGATION MOVE on a KNOT.

See also COMPLEX CONJUGATE, COMPLEX MATRIX, COMPLEX NUMBER, CONJUGATE MATRIX, CONJUGATION MOVE

Conjugation Move

A type I MARKOV MOVE.

See also MARKOV MOVES, STABILIZATION

Conjunction

A product of ANDs, denoted

$$\bigwedge_{k=1}^{n} A_k.$$

The conjunctions of a BOOLEAN ALGEBRA A of subsets of cardinality p are the 2^p functions

$$A_\lambda = \bigcup_{i \in \lambda} A_i,$$

where $\lambda \subset \{1, 2, \ldots, p\}$. For example, the 8 conjunctions of $A = \{A_1, A_2, A_3\}$ are $\varnothing$, A_1, A_2, A_3, A_1A_2, A_2A_3, A_3A_1, and $A_1A_2A_3$ (Comtet 1974, p. 186).

References

Comtet, L. *Advanced Combinatorics: The Art of Finite and Infinite Expansions, rev. enl. ed.* Dordrecht, Netherlands: Reidel, p. 186, 1974.

Conjunctive Normal Form

A statement is in conjunctive normal form if it is a CONJUNCTION (sequence of ANDs) consisting of one or more conjuncts, each of which is a DISJUNCTION (OR) of one or more statement letters and negations of statement letters. Examples of disjunctive normal forms include

$$A \quad (1)$$

$$(A \vee B) \wedge (!A \vee C) \quad (2)$$

$$(A \vee B \vee !A) \wedge (C \vee !B) \wedge (A \vee !C) \quad (3)$$

$$A \vee B \quad (4)$$

$$A \wedge (B \vee C), \quad (5)$$

where $\vee$ denotes OR, $\wedge$ denotes AND, and ! denotes NOT. Every statement in logic consisting of a combination of multiple $\wedge$, $\vee$, and !s can be written in conjunctive normal form.

See also DISJUNCTIVE NORMAL FORM

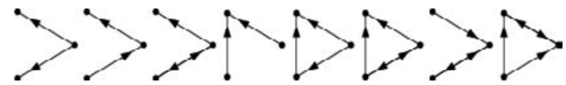
Connected Component



A TOPOLOGICAL SPACE decomposes into its connected components. The connectedness relation between two pairs of points satisfies transitivity, i.e., if $a \sim b$ and $b \sim c$ then $a \sim c$. Hence, being in the same component is an EQUIVALENCE RELATION, and the equivalence classes are the connected components.

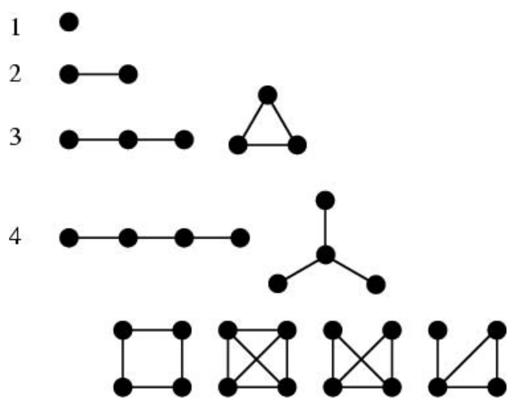
Using PATH-CONNECTEDNESS, the path-connected component containing $x \in X$ is the set of all y path-connected to x. That is, it is the set of y such that there is a continuous path from x to y.

Technically speaking, in some TOPOLOGICAL SPACES, path-connected is not the same as connected. A subset Y of X is connected if there is no way to write $Y = U \cup V$ with U and V disjoint OPEN SETS. Every TOPOLOGICAL SPACE decomposes into a disjoint union $X = \cup Y_i$ where the Y_i are connected. The Y_i are called the connected components of X.

See also CONNECTED SET, PATH-CONNECTED, TOPOLOGICAL SPACE

Connected Digraph

There are two distinct notions of connectivity in a DIGRAPH. A DIGRAPH is WEAKLY CONNECTED if there is an *undirected* path between any pair of vertices, and STRONGLY CONNECTED if there is a *directed* path between every pair of vertices (Skiena 1990, p. 173). The following tables summarized the number of weakly and strongly connected digraphs on $n = 1, 2, \ldots$ nodes. The 8 weakly but not strongly connected digraphs on three nodes are illustrated above.



connectivity	Sloane	counts
weakly connected	A003085	1, 2, 13, 199, 9364, ...
strongly connected	A035512	1, 1, 5, 83, 5048, 1047008, ...
weakly but not strongly	A056988	0, 1, 8, 116, 4316, 483835, ...

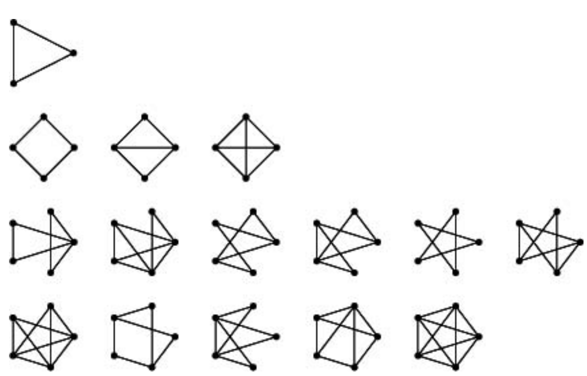
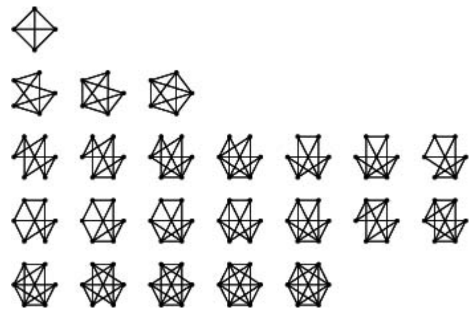
Connected Graph





A GRAPH which is connected in the sense of a TOPOLOGICAL SPACE, i.e., there is a path from any point to any other point in the GRAPH. The number of n-node connected unlabeled graphs for $n = 1, 2, \ldots$ are 1, 1, 2, 6, 21, 112, 853, 11117, ... (Sloane's A001349). The *total* number of (not necessarily connected) unlabeled n-node graphs is given by the EULER TRANSFORM of the preceding sequence, 1, 2, 4, 11, 34, 156, 1044, 12346, ... (Sloane's A000088; Sloane and Plouffe 1995, p. 20).

The numbers of connected labeled graphs on n-nodes are 1, 1, 4, 38, 728, 26704, ... (Sloane's A001187), and the *total* number of (not necessarily connected) labeled n-node graphs is given by the EXPONENTIAL TRANSFORM of the preceding sequence: 1, 2, 8, 64, 1024, 32768, ... (Sloane's A006125; Sloane and Plouffe 1995, p. 19).

If a_n is the number of unlabeled connected graphs on n nodes satisfying some property, than the EULER TRANSFORM b_n is the total number of unlabeled graphs (connected or not) with the same property. This application of the EULER TRANSFORM is called RIDDELL'S FORMULA.

If G is DISCONNECTED, then its complement $\bar{G}$ is connected (Skiena 1990, p. 171; Bollobás 1998). However, the converse is not true, as can be seen using the example of the CYCLE GRAPH C_5 which is connected and isomorphic to its complement.

One can also speak of connected graphs in which each vertex has degree at least k (i.e., the minimum of the DEGREE SEQUENCE is $\geq k$). The usual CONNECTED GRAPH is therefore connected with minimal degree ≥ 1. The following table gives the number of connected graphs with minimal degree $\geq k$ on n vertices for small k.

k	Sloane	sequence
1	A001349	1, 1, 2, 6, 21, 112, 853, 11117, ...
2	A004108	0, 0, 1, 3, 11, 61, 507, 7442, ...
3	A007112	0, 0, 0, 1, 3, 19, 150, 2589, ...

Connected Set

A connected set is a SET which cannot be partitioned into two nonempty SUBSETS which are open in the relative topology induced on the SET. Equivalently, it is a SET which cannot be partitioned into two nonempty SUBSETS such that each SUBSET has no points in common with the CLOSURE of the other.

The REAL NUMBERS are a connected set.

Connected Space

A SPACE D is connected if any two points in D can be connected by a curve lying wholly within D. A SPACE is 0-connected (a.k.a. PATHWISE-CONNECTED) if every MAP from a 0-SPHERE to the SPACE extends continuously to the 1-DISK. Since the 0-SPHERE is the two endpoints of an interval (1-DISK), every two points have a path between them. A space is 1-connected (a.k.a. SIMPLY CONNECTED) if it is 0-connected and if every MAP from the 1-SPHERE to it extends continuously to a MAP from the 2-DISK. In other words, every loop in the SPACE is CONTRACTIBLE. A SPACE is n-MULTIPLY CONNECTED if it is $(n-1)$-connected and if every MAP from the n-SPHERE into it extends continuously over the $(n+1)$-DISK.

A theorem of Whitehead says that a SPACE is infinitely connected IFF it is CONTRACTIBLE.

See also CONNECTIVITY, CONTRACTIBLE, LOCALLY PATHWISE-CONNECTED, MULTIPLY CONNECTED, PATHWISE-CONNECTED, SIMPLY CONNECTED

Connected Sum

The connected sum $M_1 \# M_2$ of n-manifolds M_1 and M_2 is formed by deleting the interiors of n-BALLS b_i^n in m_i^n and attaching the resulting punctured MANIFOLDS $M_i - \dot{B}_i$ to each other by a HOMEOMORPHISM $h : \partial B_2 \to \partial B_1$, so

$$M_1 \# M_2 = (M_1 - \dot{B}_1) \underset{h}{\cup} (M_2 - \dot{B}_2).$$

B_i is required to be interior to M_i and ∂B_i bicollared in M_i to ensure that the connected sum is a MANIFOLD.

The connected sum of two KNOTS is called a KNOT SUM.

See also KNOT SUM

References

Rolfsen, D. *Knots and Links.* Wilmington, DE: Publish or Perish Press, p. 39, 1976.

Connected Sum Decomposition

Every COMPACT 3-MANIFOLD is the CONNECTED SUM of a unique collection of PRIME 3-MANIFOLDS.

Connection

See also CONNECTION COEFFICIENT, CONNECTION (VECTOR BUNDLE), GAUSS-MANIN CONNECTION

Connection (Vector Bundle)

A connection on a VECTOR BUNDLE $\pi : E \to M$ is a way to "differentiate" SECTIONS, in a way that is analogous to the EXTERIOR DERIVATIVE df of a function f. In particular, a connection ∇ is a function from smooth sections $\Gamma(M, E)$ to smooth sections of E TENSOR with ONE-FORMS $\Gamma(M, E \otimes T^*M)$ that satisfies the following conditions.

1. $\nabla fs = s \otimes df + f \nabla s$ (Leibniz rule), and
2. $\nabla s_1 + s_2 = \nabla s_1 + \nabla s_2$.

Alternatively, a connection can be considered as a linear map from SECTIONS of $E \otimes TM$, i.e., a section of E with a VECTOR FIELD X, to sections of E, in analogy to the DIRECTIONAL DERIVATIVE. The DIRECTIONAL DERIVATIVE of a function f, in the direction of a vector field X, is given by $df(X)$. The connection, along with a vector field X, may be applied to a section s of E to get the section $\nabla_X s$. From this perspective, connections must also satisfy

$$\nabla_{fX} s = f \nabla_X s \tag{1}$$

for any smooth function f. This property follows from the first definition.

For example, the TRIVIAL BUNDLE $E = M \times \mathbb{R}^k$ admits a FLAT CONNECTION since any SECTION s corresponds to a function $\tilde{s} : M \to \mathbb{R}^k$. Then setting $\nabla s = ds$ gives the connection. Any connection on the TRIVIAL BUNDLE is of the form $\nabla s = ds + s \otimes \alpha$, where α is any ONE-FORM with values in $\mathrm{Hom}(E, E) = E^* \otimes E$, i.e., α is a matrix of ONE-FORMS.

The matrix of ONE-FORMS

$$\alpha = \begin{bmatrix} dx & 2x\,dy & 0 \\ 0 & dx - 3\,dy & 0 \\ xy\,dx & 0 & y^2\,dx + dy \end{bmatrix} \tag{2}$$

determines a connection ∇ on the rank-3 bundle over

$\mathbb{R}^2$. It acts on a section $s = (s_1, s_2, s_3)$ by the following.

$$\nabla_{\partial/\partial x} s = s_x + \alpha(\partial/\partial x)s = s_x + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ xy & 0 & y^2 \end{bmatrix} s$$

$$= (\partial s_1/\partial x + s_1,\ \partial s_2/\partial x + s_2,\ \partial s_3/\partial x + xys_1 + y^2 s_3) \quad (3)$$

$$\nabla_{\partial/\partial y} s = s_y + \alpha(\partial/\partial y)s = s_y + \begin{bmatrix} 0 & 2x & 0 \\ 0 & -3 & 0 \\ 0 & 0 & 1 \end{bmatrix} s$$

$$= (\partial s_1/\partial x + 2xs_2,\ \partial s_2/\partial x - 3s_2,\ \partial s_3/\partial x + s_3). \quad (4)$$

In any TRIVIALIZATION, a connection can be described just as in the case of a TRIVIAL BUNDLE. However, if the bundle E is not TRIVIAL, then the EXTERIOR DERIVATIVE ds is not WELL DEFINED (globally) for a SECTION s. Still, the difference between any two connections must be ONE-FORMS with values in ENDOMORPHISMS of E, i.e., matrices of one forms. So the space of connections forms an AFFINE SPACE.

The CURVATURE of the bundle is given by the formula $\Omega = \nabla \circ \nabla$. In coordinates, $\Omega = \alpha \wedge \alpha$ is matrix of TWO-FORMS. For instance, in the example above,

$$\Omega = \begin{bmatrix} 0 & 2x\,dx \wedge dy & 0 \\ 0 & -3x \wedge dy & 0 \\ 0 & 2x^3 y\,dx \wedge dy & y^2\,dx \wedge dy \end{bmatrix} \quad (5)$$

is the curvature.

Another way of describing a connection is as a splitting of the TANGENT BUNDLE TE of E as $TM \oplus E$. The vertical part of TE corresponds to tangent vectors along the fibers, and is the kernel of $d\pi : TE \to TM$. The horizontal part is not WELL DEFINED a priori. A connection defines a subspace of $TE_{(x,\,v)}$ which is isomorphic to TM_x. It defines k FLAT SECTIONS s_i such that $\nabla s_i = 0$, which are a BASIS for the FIBERS of E, at least nearby x. These flat sections determine the horizontal part of TE near x. Also, a connection on a vector bundle can be defined by a CONNECTION on the ASSOCIATED PRINCIPAL BUNDLE.

In some settings there is a canonical connection. For example, a RIEMANNIAN MANIFOLD has the LEVI-CIVITA CONNECTION, given by the CHRISTOFFEL SYMBOLS OF THE FIRST and SECOND KINDS, which is the unique torsion-free connection compatible with the metric. A HOLOMORPHIC VECTOR BUNDLE with a HERMITIAN METRIC has a unique connection which is compatible with both metric and the COMPLEX STRUCTURE.

See also CONNECTION (PRINCIPAL BUNDLE), CURVATURE, CURVATURE (BUNDLE), HERMITIAN METRIC, LEVI-CIVITA CONNECTION, PARALLEL TRANSPORT, PRINCIPAL BUNDLE, SECOND FUNDAMENTAL FORM, SECTION (BUNDLE), TORSION (BUNDLE)

Connective

A function, or the symbol representing a function, which corresponds to English conjunctions such as "and," "or," "not," etc. that takes one or more truth values as input and returns a single truth value as output. The terms "logical connective" and "propositional connective" are also used. The following table summarizes some common connectives and their notations.

connective	symbol
AND	$A \wedge B$, $A \cdot B$, $A.B$, AB, $A\&B$, $A\&\&B$
EQUIVALENT	$A \equiv B$, $A \Leftrightarrow B$, $A \rightleftharpoons B$
IMPLIES	$A \Rightarrow B$, $A \supset B$, $A \to B$
NAND	$A \bar{\wedge} B$, $A \mid B$, $\overline{A \cdot B}$
NONEQUIVALENT	$A \not\equiv B$, $A \not\Leftrightarrow B$, $A \not\rightleftharpoons B$
NOR	$A \bar{\vee} B$, $A \downarrow B$, $\overline{A + B}$
NOT	$!A$, $\neg A$, $\bar{A}$, $\sim A$
OR	$A \vee B$, $A + B$, $A \mid B$, $A \parallel B$
XNOR	A XNOR B
XOR	$A \underline{\vee} B$, $A \oplus B$

CONICAL WEDGE

Conoid

PLÜCKER'S CONOID, RIGHT CONOID

Consecutive Number Sequences

Consecutive number sequences are sequences constructed by concatenating numbers of a given type. Many of these sequences were considered by Smarandache, so they are sometimes known as SMARANDACHE SEQUENCES.

The nth term of the consecutive integer sequence consists of the concatenation of the first n POSITIVE INTEGERS: 1, 12, 123, 1234, ... (Sloane's A007908; Smarandache 1993, Dumitrescu and Seleacu 1994, sequence 1; Mudge 1995; Stephan 1998). This sequence gives the digits of the CHAMPERNOWNE CONSTANT and contains no PRIMES in the first 7,746 terms (Weisstein, Jan. 23, 2000). Fleuren (1999) has verified the absence of primes up to $n = 200$. This is roughly consistent with simple arguments based on the distribution of primes which suggest that only a single prime is expected in the first 15,000 or so terms. The number of digits of the n term can be computed by noticing the pattern in the following table, where $d = [\log_{10} n] + 1$ is the number of digits in n.

d	n Range	Digits
1	1–	n
2	10–9	$9+2(n-9)$
3	100–99	$9+90\cdot 2+3(n-99)$
4	1000–999	$9+90\cdot 2+900\cdot 3+4(n-999)$

Therefore, the number of digits $D(n)$ in the nth term can be written

$$D(n) = d(n+1-10^{d-1}) + \sum_{k=1}^{d-1} 9k\cdot 10^{k-1}$$

$$= (n+1)d - \frac{10^d - 1}{9},$$

where the second term is the REPUNIT R_d.

The nth term of the reverse integer sequence consists of the concatenation of the first n POSITIVE INTEGERS written backwards: 1, 21, 321, 4321, ... (Sloane's A000422; Smarandache 1993, Dumitrescu and Seleacu 1994, Stephan 1998). The only PRIME in the first 7,287 terms (Weisstein, Jan. 23, 2000) of this sequence is the 82nd term 828180...321 (Stephan 1998, Fleuren 1999), which has 155 digits. This is roughly consistent with simple arguments based on the distribution of prime which suggest that a single prime is expected in the first 15,000 or so terms. The terms of the reverse integer sequence have the same number of digits as do the consecutive integer sequence.

The concatenation of the first n PRIMES gives 2, 23, 235, 2357, 235711, ... (Sloane's A019518; Smith 1996, Mudge 1997). This sequence converges to the digits of the COPELAND-ERDOS CONSTANT and is PRIME for terms 1, 2, 4, 128, 174, 342, 435, 1429, ... (Sloane's A046035; Ibstedt 1998, pp. 78–9), with no others less than 4,706 (Weisstein, Jan. 23, 2000).

The concatenation of the first n ODD NUMBERS gives 1, 13, 135, 1357, 13579, ... (Sloane's A019519; Smith 1996, Marimutha 1997, Mudge 1997). This sequence is PRIME for terms 2, 10, 16, 34, 49, 2570, ... (Sloane's A046036; Weisstein, Ibstedt 1998, pp. 75–6), with no others less than 4,354 (Weisstein, Jan. 1, 2000). The 2570th term, given by 1 3 5 7...5137 5139, has 9725 digits and was discovered by Weisstein in Aug. 1998.

The concatenation of the first n EVEN NUMBERS gives 2, 24, 246, 2468, 246810, ... (Sloane's A019520; Smith 1996; Marimutha 1997; Mudge 1997; Ibstedt 1998, pp. 77–8).

The concatenation of the first n SQUARE NUMBERS gives 1, 14, 149, 14916, ... (Sloane's A019521; Marimutha 1997). The only PRIME in the first 2,822 terms is the third term, 149, (Weisstein).

The concatenation of the first n CUBIC NUMBERS gives 1, 18, 1827, 182764, ... (Sloane's A019522; Marimutha 1997). There are no PRIMES in the first 2,652 terms (Weisstein).

Conservation of Number Principle

A generalization of Poncelet's CONTINUITY PRINCIPLE made by H. Schubert in 1874–9. The conservation of number principle asserts that the number of solutions of any determinate algebraic problem in any number of parameters under variation of the parameters is invariant in such a manner that no solutions become INFINITE. Schubert called the application of this technique the CALCULUS of ENUMERATIVE GEOMETRY.

Conservative Field

The following conditions are equivalent for a conservative VECTOR FIELD:

1. For any oriented simple closed curve C, the LINE INTEGRAL $\oint_C \mathbf{F} \cdot d\mathbf{s} = 0$.
2. For any two oriented simple curves C_1 and C_2 with the same endpoints, $\int_{C_1} \mathbf{F} \cdot d\mathbf{s} = \int_{C_2} \mathbf{F} \cdot d\mathbf{s}$.
3. There exists a SCALAR POTENTIAL FUNCTION f such that $\mathbf{F} = \nabla f$, where ∇ is the GRADIENT.
4. The CURL $\nabla \times \mathbf{F} = 0$.

See also CURL, GRADIENT, LINE INTEGRAL, POINCARÉ'S THEOREM, POTENTIAL FUNCTION, VECTOR FIELD

Consistency

The absence of CONTRADICTION (i.e., the ability to prove that a statement and its negative are both true) in an AXIOMATIC SYSTEM is known as consistency.

See also AXIOMATIC SET THEORY, AXIOMATIC SYSTEM, COMPLETE AXIOMATIC THEORY, CONSISTENCY STRENGTH, GÖDEL'S INCOMPLETENESS THEOREM

Consistency Strength

If the CONSISTENCY of one of two propositions implies the CONSISTENCY of the other, the first is said to have greater consistency strength.

Constant

Any REAL NUMBER which is "significant" (or interesting) in some way. In this work, the term "constant" is generally reserved for REAL nonintegral numbers of interest, while "NUMBER" is reserved for interesting INTEGERS (e.g., BRUN'S CONSTANT, but BEAST NUMBER). In contexts like LINEAR COMBINATION, the term "constant" is generally used to mean "SCALAR" or "REAL NUMBER," and need not exclude integer values.

Certain constants are known to many DECIMAL DIGITS and recur throughout many diverse areas of mathematics, often in unexpected and surprising places (e.g., PI, E, and to some extent, the EULER-MASCHERONI CONSTANT γ). Other constants are more specialized and may be known to only a few DIGITS. S. Plouffe maintains a site about the computation and identification of numerical constants. Plouffe's site also contains a page giving the largest number of DIGITS computed for the most common constants. S. Finch maintains a delightful, more expository site containing detailed essays and references on constants both common and obscure.

The mathematician Glaisher remarked, "No doubt the desire to obtain the values of these quantities to a great many figures is also partly due to the fact that most of them are interesting in themselves; for e, π, γ, 1n 2, and many other numerical quantities occupy a curious, and some of them almost a mysterious, place in mathematics, so that there is a natural tendency to do all that can be done towards their precise determination" (Gourdon and Sebah).

Constant Function

A FUNCTION $f(x)=c$ which does not change as its parameters vary. The GRAPH of a 1-D constant FUNCTION is a straight LINE. The DERIVATIVE of a constant FUNCTION c is

$$\frac{d}{dx}c=0, \tag{1}$$

and the INTEGRAL is

$$\int c\,dx=cx. \tag{2}$$

The FOURIER TRANSFORM of the constant function $f(x)=1$ is given by

$$\mathcal{F}[1]=\int_{-\infty}^{\infty} e^{-2\pi ikx}\,dx=\delta(k), \tag{3}$$

where $\delta(k)$ is the DELTA FUNCTION.

Constant Precession Curve

CURVE OF CONSTANT PRECESSION

Constant Problem

Given an expression involving known constants, integration in finite terms, computation of limits, etc., determine if the expression is equal to ZERO. The constant problem is a very difficult unsolved problem in transcendental NUMBER THEORY. However, it is known that the problem is UNDECIDABLE if the expression involves oscillatory functions such as SINE. However, the FERGUSON-FORCADE ALGORITHM is a practical algorithm for determining if there exist integers a_i for given real numbers x_i such that

$$a_1x_1+a_2x_2+\ldots+a_nx_n=0,$$

or else establish bounds within which no relation can exist (Bailey 1988).

Constant Width Curve

CURVE OF CONSTANT WIDTH

Constructible Number

A number which can be represented by a FINITE number of ADDITIONS, SUBTRACTIONS, MULTIPLICATIONS, DIVISIONS, and FINITE SQUARE ROOT extractions of integers. Such numbers correspond to LINE SEGMENTS which can be constructed using only STRAIGHTEDGE and COMPASS.

All RATIONAL NUMBERS are constructible, and all constructible numbers are ALGEBRAIC NUMBERS (Courant and Robbins 1996, p. 133). If a CUBIC EQUATION with rational coefficients has no rational root, then none of its roots is constructible (Courant and Robbins, p. 136).

In particular, let F_0 be the FIELD of RATIONAL NUMBERS. Now construct an extension field F_1 of constructible numbers by the adjunction of $\sqrt{k_0}$, where k_0 is in F_0, but $\sqrt{k_0}$ is not, consisting of all numbers OF THE FORM $a_0+b_0\sqrt{k_0}$, where $a_0,\ b_0\in F_0$. Next, construct an extension field F_2 of F_1 by the adjunction of $\sqrt{K_1}$, defined as the numbers $a_1+b_1\sqrt{k_1}$, where $a_1,\ b_1\in F_1$, and k_1 is a number in F_1 for which $\sqrt{K_1}$ does not lie in F_1. Continue the process n times. Then constructible numbers are precisely those which can be reached by such a sequence of extension fields F_n, where n is a measure of the

"complexity" of the construction (Courant and Robbins 1996).

Constructible Polygon

compass and straightedge constructions dating back to Euclid were capable of inscribing regular polygons of 3, 4, 5, 6, 8, 10, 12, 16, 20, 24, 32, 40, 48, 64, ..., sides. However, this listing is not a complete enumeration of "constructible" polygons. A regular n-gon ($n \geq 3$) can be constructed by straightedge and compass iff

$$n = 2^k p_1 p_2 \cdots p_s,$$

where k is in integer ≥ 0 and the p_i are distinct Fermat primes. Fermat numbers are of the form

$$F_m = 2^{2^m} + 1,$$

where m is an integer ≥ 0. The only known primes of this form are 3, 5, 17, 257, and 65537. The fact that this condition was sufficient was first proved by Gauss in 1796 when he was 19 years old. That this condition was also necessary was not explicitly proven by Gauss, and the first proof of this fact is credited to Wantzel (1836).

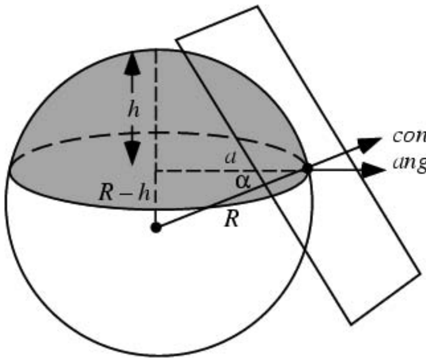
Construction



Braikenridge-Maclaurin Construction, Constructible Number, Constructible Polygon, Constructive Dilemma, Geometric Construction, Hauy Construction, Mascheroni Construction, Matchstick Construction, Neusis Construction, Paley Construction, Steiner Construction, Wythoff Construction

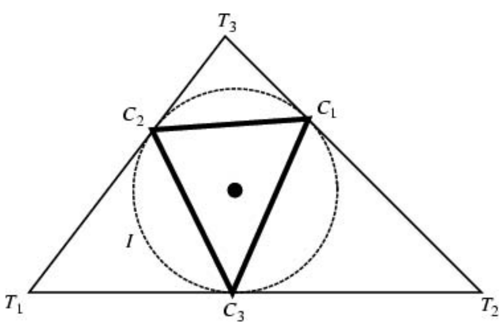
Constructive Dilemma

A formal argument in logic in which it is stated that (1) $P \Rightarrow Q$ and $R \Rightarrow S$ (where $\Rightarrow$ means "implies"), and (2) either P or R is true, from which two statements it follows that either Q or S is true.

See also Destructive Dilemma, Dilemma

Contact Angle

The ANGLE α between the normal vector of a SPHERE (or other geometric object) at a point where a PLANE is tangent to it and the normal vector of the plane. In the above figure,



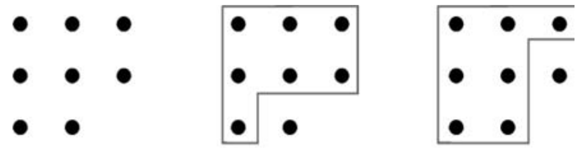
$$\alpha = \cos^{-1}\left(\frac{a}{R}\right) = \sin^{-1}\left(\frac{R-h}{R}\right).$$

See also SPHERICAL CAP

Contact Number

KISSING NUMBER

Contact Triangle



The TRIANGLE formed by the points of intersection of a TRIANGLE T's INCIRCLE with T. This is the PEDAL TRIANGLE of T with the INCENTER as the PEDAL POINT (cf., TANGENTIAL TRIANGLE). The lines from the vertices of the contact triangle to the vertices of the original triangle CONCUR in the GERGONNE POINT. Furthermore, the contact triangle and TANGENTIAL TRIANGLE are perspective from the GERGONNE POINT.

Contained Partition

A PARTITION p is said to contain another partition q if the FERRERS DIAGRAM of p contains the FERRERS DIAGRAM of q. For example, $\{3, 3, 2\}$ (left figure) contains both $\{3, 3, 1\}$ and $\{3, 3, 2\}$ (right figures). YOUNG'S LATTICE Y_P is the PARTIAL ORDER of partitions contained within p ordered by containment (Skiena 1990, p. 77).

See also PARTITION, YOUNG'S LATTICE

References

Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, 1990.

Contained Pattern

A subset $\tau \in S_n$ of a permutation $\{1, \ldots, n\}$ is said to contain $\alpha \in S_k$ if there exist $1 \leq i_1 < \ldots < i_k \leq n$ such that $\tau = (\tau_i, \ldots, \tau_k)$ is ORDER ISOMORPHIC to $\alpha = (\alpha_1, \ldots, \alpha_k)$. Here, S_n is the SYMMETRIC GROUP on n elements.

In other words, τ contains α IFF any K-SUBSET of τ is ORDER ISOMORPHIC to α.

References

Mansour, T. Permutations Avoiding a Pattern from S_k and at Least Two Patterns from S_3. 31 Jul 2000. http://xxx.lanl.gov/abs/math.CO/0007194/.

Content

The content of a POLYTOPE or other n-dimensional object is its generalized VOLUME (i.e., its "hypervolume"). Just as a three-dimensional object has VOLUME, SURFACE AREA, and GENERALIZED DIAMETER, an n-dimensional object has "measures" of order 1, 2, ..., n.

The content of an integer polynomial $P \in \mathbb{Z}(x)$, denoted cont(P), is the largest integer $k \geq 1$ such that P/k also has integer coefficients. Gauss's lemma for contents states that if P and Q are two polynomials with integer coefficients, then $\mathrm{cont}(PQ) = \mathrm{cont}(P)\mathrm{cont}(Q)$ (Séroul 2000, p. 287).

Contests

MATHEMATICS CONTESTS

Contiguous Function

A HYPERGEOMETRIC FUNCTION in which one parameter changes by +1 or −1 is said to be contiguous. There are 26 functions contiguous to ${}_2F_1(a,\ b;\ c;\ x)$ taking one pair at a time. There are 325 taking two or more pairs at a time. See Abramowitz and Stegun (1972, pp. 557–58).

See also HYPERGEOMETRIC FUNCTION

References

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing.* New York: Dover, 1972.

Contingency

A SENTENCE is called a contingency if its TRUTH TABLE contains at least one 'T' and at least one 'F.'

See also CONTRADICTION, TAUTOLOGY, TRUTH TABLE

References

Carnap, R. *Introduction to Symbolic Logic and Its Applications.* New York: Dover, p. 13, 1958.

Continued Fraction

A "general" continued fraction representation of a REAL NUMBER x is OF THE FORM

$$x = a_0 + \cfrac{b_1}{a_1 + \cfrac{b_2}{a_2 + \cfrac{b_3}{a_3 + \ldots}}}, \tag{1}$$

which can be written

$$x = a_0 + \frac{b_1}{a_1 +}\ \frac{b_2}{a_2 +} \ldots. \tag{2}$$

An archaic word for a continued fraction is ANTHYPHAIRETIC RATIO.

The SIMPLE CONTINUED FRACTION representation of a number x (which is usually what is meant when the term "continued fraction" is used without qualification) is given by

$$x = a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{a_3 + \ldots}}}, \tag{3}$$

which can be written in a compact abbreviated NOTATION as

$$x = [a_0,\ a_1,\ a_2,\ a_3,\ \ldots]. \tag{4}$$

Some care is needed, since some authors begin indexing the terms at a_1 instead of a_0, causing the parity of certain fundamental results in continued fraction theory to be reversed. Starting the indexing with a_0,

$$a_0 = \lfloor x \rfloor \tag{5}$$

is the integral part of x, where $\lfloor x \rfloor$ is the FLOOR FUNCTION,

$$a_1 = \left\lfloor \frac{1}{x - a_0} \right\rfloor \tag{6}$$

is the integral part of the RECIPROCAL of $x - a_0$,

$$a_2 = \left\lfloor \cfrac{1}{\cfrac{1}{x - a_0} - a_1} \right\rfloor \tag{7}$$

is the integral part of the reciprocal of the remainder, etc. Writing the remainders according to the RECURRENCE RELATION

$$r_0 = x \tag{8}$$

$$r_n = \frac{1}{r_{n-1} - a_{n-1}} \tag{9}$$

gives the concise formula

$$a_n = \lfloor r_n \rfloor. \tag{10}$$

The quantities a_n are called PARTIAL QUOTIENTS, and the quantity obtained by including n terms of the continued fraction

$$c_n = \frac{p_n}{q_n} = [a_0,\ a_1,\ \ldots,\ a_n] = a_0 + \cfrac{1}{a_1 + \cfrac{1}{a_2 + \cfrac{1}{\ldots + \cfrac{1}{a_n}}}} \tag{11}$$

is called the nth CONVERGENT. For example, consider the computation of the continued fraction of π, given by $\pi = [3,\ 7,\ 15,\ 1,\ 292,\ 1,\ 1,\ \ldots]$.

Term	Value	PQs	Convergent	Value
a_0	$\lfloor \pi \rfloor = 3$	[3]	3	3.00000
a_1	$\left\lfloor \frac{1}{\pi - 3} \right\rfloor = 7$	[3, 7]	$\frac{22}{7}$	3.14286
a_2	$\left\lfloor \frac{1}{\frac{1}{\pi-3} - 7} \right\rfloor = 15$	[3, 7, 15]	$\frac{333}{106}$	3.14151

Continued fractions provide, in some sense, a series of "best" estimates for an IRRATIONAL NUMBER. Functions can also be written as continued fractions, providing a series of better and better rational approximations. Continued fractions have also proved useful in the proof of certain properties of numbers such as e and π (PI). Because irrationals which are square roots of RATIONAL NUMBERS have periodic continued fractions, an exact representation for a tabulated numerical value (i.e., 1.414... for PYTHAGORAS'S CONSTANT, $\sqrt{2}$) can sometimes be found if it is suspected to represent an unknown QUADRATIC SURD.

Continued fractions are also useful for finding near commensurabilities between events with different periods. For example, the Metonic cycle used for calendrical purposes by the Greeks consists of 235 lunar months which very nearly equal 19 solar years, and 235/19 is the sixth CONVERGENT of the ratio of the lunar phase (synodic) period and solar period (365.2425/29.53059). Continued fractions can also be used to calculate gear ratios, and were used for this purpose by the ancient Greeks (Guy 1990).

Let P_n/Q_n be convergents of a *nonsimple* continued fraction. Then

$$P_{-1} \equiv 1 \quad Q_{-1} \equiv 0 \tag{12}$$

$$P_0 \equiv a_0 \quad Q_0 \equiv 1 \tag{13}$$

and subsequent terms are calculated from the RECURRENCE RELATIONS

$$P_j = a_j P_{j-1} + b_j P_{j-2} \tag{14}$$

$$Q_j = a_j Q_{j-1} + b_j Q_{j-2} \tag{15}$$

for $j = 1, 2, ..., n$. It is also true that

$$P_n Q_{n-1} - P_{n-1} Q_n = (-1)^{n-1} \prod_{k=1}^{n} b_k. \tag{16}$$

The error in approximating a number by a given CONVERGENT is roughly the MULTIPLICATIVE INVERSE of the square of the DENOMINATOR of the first neglected term.

A *finite simple* continued fraction representation terminates after a finite number of terms. To "round" a continued fraction, truncate the last term unless it is ± 1, in which case it should be added to the previous term (Gosper 1972, Item 101A). To take one over a continued fraction, add (or possibly delete) an initial 0 term. To negate, take the NEGATIVE of all terms, optionally using the identity

$$\begin{aligned}[-a, -b, -c, -d, \ldots] \\ = [-a-1, 1, b-1, c, d, \ldots].\end{aligned} \tag{17}$$

A particularly beautiful identity involving the terms of the continued fraction is

$$\frac{[a_0, a_1, \ldots, a_n]}{[a_0, a_1, \ldots, a_{n-1}]} = \frac{[a_n, a_{n-1}, \ldots, a_1, a_0]}{[a_n, a_{n-1}, \ldots, a_1]}. \tag{18}$$

Finite simple fractions represent rational numbers and all rational numbers are represented by finite continued fractions. There are two possible representations for a finite simple fraction:

$$[a_0, \ldots, a_n] = \begin{cases} [a_0, \ldots, a_{n-1}, a_n - 1, 1] & \text{for } a_n > 1 \\ [a_0, \ldots, a_{n-2}, a_{n-1} + 1] & \text{for } a_n = 1 \end{cases} \tag{19}$$

On the other hand, an infinite simple fraction represents a unique IRRATIONAL NUMBER, and each IRRATIONAL NUMBER has a unique infinite continued fraction.

Consider the CONVERGENTS $c_n = p_n/q_n$ of a *simple* continued fraction, and define

$$p_{-2} \equiv 0 \quad q_{-2} \equiv 1 \tag{20}$$

$$p_{-1} \equiv 1 \quad q_{-1} \equiv 0 \tag{21}$$

$$p_0 \equiv a_0 \quad q_0 \equiv 1. \tag{22}$$

Then subsequent terms can be calculated from the RECURRENCE RELATIONS

$$p_n = a_n p_{n-1} + p_{n-2} \tag{23}$$

$$q_n = a_n q_{n-1} + q_{n-2}. \tag{24}$$

The CONTINUED FRACTION FUNDAMENTAL RECURRENCE RELATION for *simple* continued fractions is

$$p_n q_{n-1} - p_{n-1} q_n = (-1)^{n+1}. \tag{25}$$

It is also true that if $a_0 \neq 0$,

$$\frac{p_n}{p_{n-1}} = [a_n, a_{n-1}, \ldots, a_0] \tag{26}$$

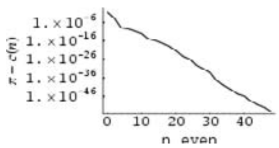
$$\frac{q_n}{q_{n-1}} = [a_n, \ldots, a_1]. \tag{27}$$

Furthermore,

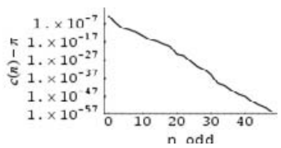
$$\frac{p_n}{q_n} = \frac{p_{n+1} - p_{n-1}}{q_{n+1} - q_{n-1}}. \tag{28}$$

Also, if a convergent $c_n = p_n/q_n > 1$, then

$$\frac{q_n}{p_n} = [0, a_0, a_1, \ldots, a_n]. \tag{29}$$



Similarly, if $c_n = p_n/q_n < 1$, then $a_0 = 0$ and



$$\frac{q_n}{p_n} = [a_1, \ldots, a_n]. \tag{30}$$

The convergents $c_n = p_n/q_n$ also satisfy

$$c_n - c_{n-1} = \frac{(-1)^{n+1}}{q_n q_{n-1}} \tag{31}$$

$$c_n - c_{n-2} = \frac{a_n(-1)^n}{q_n q_{n-2}}. \tag{32}$$

Plotted above on semilog scales are $c_n - \pi$ (n even; left figure) and $\pi - c_n$ (n odd; right figure) as a function of n for the convergents of π. In general, the EVEN convergents c_{2n+1} of an infinite simple continued fraction for a number x form an INCREASING SEQUENCE, and the ODD convergents c_{2n} form a DECREASING SEQUENCE (so any EVEN convergent is less than any ODD convergent). Summarizing,

$$c_0 < c_2 < c_4 < \cdots < c_{2n-2} < c_{2n} < \cdots < x \tag{33}$$

$$x < \cdots < c_{2n+1} < c_{2n-1} < c_5 < c_3 < c_1. \tag{34}$$

Furthermore, each convergent for $n \geq 3$ lies between the two preceding ones. Each convergent is nearer to the value of the infinite continued fraction than the previous one. In addition, for a number $x = [a_0, a_1, \ldots]$,

$$\frac{1}{(a_{n+1}+2)q_n^2} < \left| x - \frac{p_n}{q_n} \right| < \frac{1}{a_{n+1}q_n^2}. \tag{35}$$

The SQUARE ROOT of a SQUAREFREE INTEGER has a periodic continued fraction OF THE FORM

$$\sqrt{n} = [a_0, \overline{a_1, \ldots, a_n, 2a_0}] \tag{36}$$

(Rose 1994, p. 130). Furthermore, if D is not a SQUARE NUMBER, then the terms of the continued fraction of $\sqrt{D}$ satisfy

$$0 < a_n < 2\sqrt{D}. \tag{37}$$

In particular,

$$[\bar{a}] = \frac{a + \sqrt{a^2+4}}{2} \tag{38}$$

$$[1, \bar{a}] = \frac{-1 + \sqrt{1+4a}}{2} \tag{39}$$

$$[a, \overline{2a}] = \sqrt{a^2+1} \tag{40}$$

$$[\overline{a, b}] = \frac{ab\sqrt{ab + (ab(ab+4)}}{2b} \tag{41}$$

$$[\overline{a_1, \ldots, a_n}] = \frac{-(q_{n-1}-p_n) + \sqrt{(q_{n-1}-p_n)^2 + 4q_n p_{n-1}}}{2q_n} \tag{42}$$

$$[a_0, \overline{b_1, \ldots, b_n}] = a_0 + \frac{1}{[\overline{b_1, \ldots, b_n}]} \tag{43}$$

$$[\overline{b_1, \ldots, b_n}] = \frac{[\overline{b_1, \ldots, b_n}]p_n + p_{n-1}}{[\overline{b_1, \ldots, b_n}]q_n + q_{n-1}}. \tag{44}$$

The first follows from

$$\begin{aligned} \alpha &= n + \cfrac{1}{n + \cfrac{1}{n + \cfrac{1}{n + \ldots}}} \\ &= n + \cfrac{1}{n + \left(\cfrac{1}{n + \cfrac{1}{n + \ldots}} \right)}. \end{aligned} \tag{45}$$

Therefore,

$$\alpha - n = \cfrac{1}{n + \cfrac{1}{n + \cfrac{1}{n + \ldots}}}, \tag{46}$$

so plugging (46) into (45) gives

$$\alpha = n + \frac{1}{n + (\alpha - n)} = n + \frac{1}{\alpha}. \tag{47}$$

Expanding

$$\alpha^2 - n\alpha - 1 = 0, \tag{48}$$

and solving using the QUADRATIC FORMULA gives

$$\alpha = \frac{n + \sqrt{n^2+4}}{2}. \tag{49}$$

The analog of this treatment in the general case gives

$$\alpha = \frac{\alpha p_n + p_{n-1}}{\alpha q_n + q_{n-1}}. \tag{50}$$

The following table gives the repeating simple continued fractions for the square roots of the first few integers (excluding the trivial SQUARE NUMBERS).

N	$\alpha\sqrt{N}$	N	$\alpha\sqrt{N}$
2	$[1, \bar{2}]$	22	$[4, \overline{1, 2, 4, 2, 1, 8}]$
3	$[1, \overline{1, 2}]$	23	$[4, \overline{1, 3, 1, 8}]$
5	$[2, \bar{4}]$	24	$[4, \overline{1, 8}]$

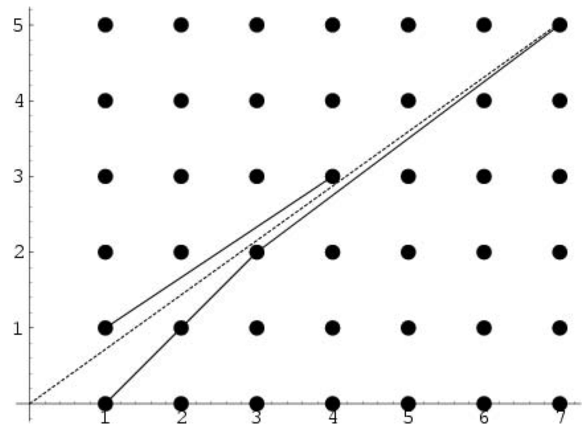
6	$[2, \overline{2, 4}]$	26	$[5, \overline{10}]$
7	$[2, \overline{1, 1, 1, 4}]$	27	$[5, \overline{5, 10}]$
8	$[2, \overline{1, 4}]$	28	$[5, \overline{3, 2, 3, 10}]$
10	$[3, \overline{6}]$	29	$[5, \overline{2, 1, 1, 2, 10}]$
11	$[3, \overline{3, 6}]$	30	$[5, \overline{2, 10}]$
12	$[3, \overline{2, 6}]$	31	$[5, \overline{1, 1, 3, 5, 3, 1, 1, 10}]$
13	$[3, \overline{1, 1, 1, 1, 6}]$	32	$[5, \overline{1, 1, 1, 10}]$
14	$[3, \overline{1, 2, 1, 6}]$	33	$[5, \overline{1, 2, 1, 10}]$
15	$[3, \overline{1, 6}]$	34	$[5, \overline{1, 4, 1, 10}]$
17	$[4, \overline{8}]$	35	$[5, \overline{1, 10}]$
18	$[4, \overline{4, 8}]$	37	$[6, \overline{12}]$
19	$[4, \overline{2, 1, 3, 1, 2, 8}]$	38	$[6, \overline{6, 12}]$
20	$[4, \overline{2, 8}]$	39	$[6, \overline{4, 12}]$
21	$[4, \overline{1, 1, 2, 1, 1, 8}]$	40	$[6, \overline{3, 12}]$

The periods of the continued fractions of the square roots of the first few nonsquare integers 2, 3, 5, 6, 7, 8, 10, 11, 12, 13, ... (Sloane's A000037) are 1, 2, 1, 2, 4, 2, 1, 2, 2, 5, ... (Sloane's A013943; Williams 1981, Jacobson *et al.* 1995). An upper bound for the length is roughly $\mathcal{O}(\ln D\sqrt{D})$.

An even stronger result is that a continued fraction is periodic IFF it is a ROOT of a quadratic POLYNOMIAL. Calling the portion of a number x remaining after a given convergent the "tail," it must be true that the relationship between the number x and terms in its tail is OF THE FORM

$$x = \frac{ax + b}{cd + d}, \tag{51}$$

which can only lead to a QUADRATIC EQUATION.



LOGARITHMS $\log_{b_0} b_1$ can be computed by defining b_2, ... and the POSITIVE INTEGER n_1, ...such that

$$b_1^{n_1} < b_0 < b_1^{n_1+1} \quad b_2 = \frac{b_0}{b_1^{n_1}} \tag{52}$$

$$b_2^{n_2} < b_1 < b_2^{n_2+1} \quad b_3 = \frac{b_1}{b_2^{n_2}} \tag{53}$$

and so on. Then

$$\log_{b_0} b_1 = [n_1, n_2, n_3, ...]. \tag{54}$$

A geometric interpretation for a reduced FRACTION y/x consists of a string through a LATTICE of points with ends at (1, 0) and (x, y) (Klein 1907, 1932; Steinhaus 1983, p. 40; Gardner 1984, pp. 210–11, Ball and Coxeter 1987, pp. 86–7; Davenport 1992). This interpretation is closely related to a similar one for the GREATEST COMMON DIVISOR. The pegs it presses against (x_i, y_i) give alternate CONVERGENTS y_i/x_i, while the other CONVERGENTS are obtained from the pegs it presses against with the initial end at (0, 1). The above plot is for $e-2$, which has convergents 0, 1, 2/3, 3/4, 5/7, ...

Let the continued fraction for x be written $[a_0, a_1, ..., a_n]$. Then the limiting value is *almost always* KHINTCHINE'S CONSTANT

$$K \equiv \lim_{n\to\infty} (a_1 a_2 \ldots a_n)^{1/n} = 2.68545\ldots. \tag{55}$$

Continued fractions can be used to express the POSITIVE ROOTS of any POLYNOMIAL equation. Continued fractions can also be used to solve linear DIOPHANTINE EQUATIONS and the PELL EQUATION. Euler showed that if a CONVERGENT SERIES can be written in the form

$$c_1 + c_1c_2 + c_1c_2c_3 + \ldots, \tag{56}$$

then it is equal to the continued fraction

$$\cfrac{c_1}{1 - \cfrac{c_2}{1 + c_2 - \cfrac{c_3}{1 + c_3 - \ldots}}}. \tag{57}$$

Gosper has invented an ALGORITHM for performing analytic ADDITION, SUBTRACTION, MULTIPLICATION, and DIVISION using continued fractions. It requires keeping track of eight INTEGERS which are conceptually arranged at the VERTICES of a CUBE. Although this ALGORITHM has not appeared in print, similar algorithms have been constructed by Vuillemin (1987) and Liardet and Stambul (1998).

Gosper's algorithm for computing the continued fraction for $(ax+b)/(cx+d)$ from the continued fraction

for x is described by Gosper (1972), Knuth (1981, Exercise 4.5.3.15, pp. 360 and 601), and Fowler (1999). (In line 9 of Knuth's solution, $X_k \leftarrow \lfloor A/C \rfloor$ should be replaced by $X_k \leftarrow \min(\lfloor A/C \rfloor, \lfloor (A+B)/(C+D) \rfloor)$.) Gosper (1972) and Knuth (1981) also mention the bivariate case $(axy+bx+cy+d)/(Axy+Bx+Cy+D)$.

Ramanujan developed a number of interesting closed-form expressions for continued fractions, including

$$\frac{1}{1+}\,\frac{e^{-2\pi}}{1+}\,\frac{e^{-4\pi}}{1+\ldots} = \left[\sqrt{\frac{5+\sqrt{5}}{2}} - \frac{\sqrt{5}+1}{2}\right] e^{2\pi/5} \tag{58}$$

$$\frac{1}{1+}\,\frac{e^{-2\pi\sqrt{5}}}{1+}\,\frac{e^{-4\pi\sqrt{5}}}{1+\ldots} = \left\{ \frac{\sqrt{5}}{1+\left[5^{3/4}\left(\frac{\sqrt{5}-1}{2}\right)^{5/2} - 1\right]} - \frac{\sqrt{5}+1}{2} \right\} e^{2\pi/\sqrt{5}} \tag{59}$$

and

$$4\int_0^\infty \frac{xe^{-2\sqrt{5}}}{\cosh x}\,dx = \tfrac{1}{2}[\zeta(2,\,\tfrac{1}{4}(1+\sqrt{5})) - \zeta(2,\,\tfrac{1}{4}(3+\sqrt{5})]$$
$$= \frac{1}{1+}\,\frac{1^2}{1+}\,\frac{1^2}{1+}\,\frac{2^2}{1+}\,\frac{2^2}{1+}\,\frac{3^2}{1+}\,\frac{3^2}{1+} \tag{60}$$

(Watson 1929; Preece 1931; Watson 1931; Hardy 1999, p. 8).

Continued Fraction Constant

A continued fraction with partial quotients which increase in ARITHMETIC PROGRESSION is

$$[A+D,\ A+2D,\ A+3D,\ \ldots] = \frac{I_{A/D}\left(\frac{2}{D}\right)}{I_{1+A/D}\left(\frac{2}{D}\right)},$$

where $I_n(x)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND (Schroeppel 1972). A special case is

$$C = 0 + \cfrac{1}{1 + \cfrac{1}{2 + \cfrac{1}{3 + \cfrac{1}{4 + \cfrac{1}{5 + \ldots}}}}},$$

which has the value

$$C = \frac{I_1(2)}{I_0(2)} = 0.697774658\ldots$$

(Lehmer 1973, Rabinowitz 1990).

Continued Fraction Factorization Algorithm

A PRIME FACTORIZATION ALGORITHM which uses RESIDUES produced in the CONTINUED FRACTION of $\sqrt{mN}$ for some suitably chosen m to obtain a SQUARE NUMBER. The ALGORITHM solves

$$x^2 \equiv y^2 \pmod{n}$$

by finding an m for which $m^2 \pmod{n}$ has the smallest upper bound. The method requires (by conjecture) about $\exp(\sqrt{2 \ln n \ln \ln n})$ steps, and was the fastest PRIME FACTORIZATION ALGORITHM in use before the QUADRATIC SIEVE, which eliminates the 2 under the SQUARE ROOT (Pomerance 1996), was developed.

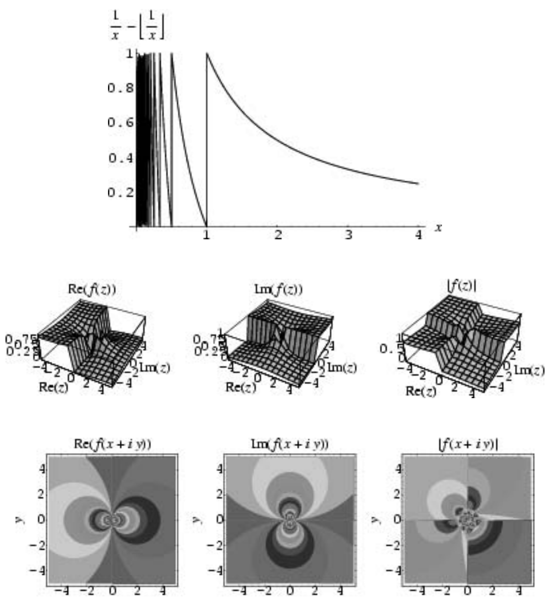
Continued Fraction Fundamental Recurrence Relation

For a SIMPLE CONTINUED FRACTION $x = [a_0, a_1, \ldots]$ with CONVERGENTS p_n/q_n, the fundamental RECUR-

RENCE RELATION is given by



$$p_n q_{n-1} - p_{n-1} q_n = (-1)^{n+1}.$$

Continued Fraction Map

$$f(x) = \frac{1}{x} - \left\lfloor \frac{1}{x} \right\rfloor$$

for $x \in [0, 1]$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION. The NATURAL INVARIANT of the map is

$$\rho(y) = \frac{1}{(1+y)\ln 2}.$$

Continuity Axioms

"The" continuity axiom is an additional AXIOM which must be added to those of Euclid's *ELEMENTS* in order to guarantee that two equal CIRCLES of RADIUS r intersect each other if the separation of their centers is less than $2r$ (Dunham 1990). The continuity *axioms* are the three of HILBERT'S AXIOMS which concern geometric equivalence.

ARCHIMEDES' LEMMA is sometimes also known as "the continuity axiom."

Continuity Correction

A correction to a discrete BINOMIAL DISTRIBUTION to approximate a continuous distribution.

$$P(a \leq X \leq b) \approx P\left(\frac{a - \frac{1}{2} - np}{\sqrt{np(1-p)}} \leq z \leq \frac{b + \frac{1}{2} - np}{\sqrt{np(1-p)}}\right),$$

where

$$z \equiv \frac{(x-\mu)}{\sigma}$$

is a continuous variate with a normal distribution and X is a variate of a binomial distribution.

Continuity Principle

The metric properties discovered for a primitive figure remain applicable, without modifications other than changes of signs, to all correlative figures which can be considered to arise from the first. As stated by Lachlan (1893), the principle states that if, from the nature of a particular problem, a certain number of solutions are expected (and are, in fact, found in any one case), then there will be the same number of solutions in all cases, although some solutions may be imaginary.

For example, two circles intersect in two points, so it can be stated that every two circles intersect in two points, although the points may be imaginary or may coincide. The principle is extremely powerful (if somewhat difficult to state precisely), and allows immediate derivation of some geometric propositions from other propositions which may appear simpler and may be substantially easier to prove.

The continuity principle was first enunciated by Kepler and thereafter enunciated by Boscovich. However, it was not generally accepted until formulated by Poncelet in 1822. Formally, it amounts to the statement that if an analytic identity in any finite number of variables holds for all real values of the variables, then it also holds by analytic continuation for all complex values (Bell 1945). This principle is also called "Poncelet's continuity principle," or sometimes the "permanence of mathematical relations principle" (Bell 1945).

Continuous

A general mathematical property obeyed by mathematical objects in which all elements are within a neighborhood of nearby points. The continuous maps between topological spaces form a category. The designation "continuous" is sometimes used to indicate membership in this category.

Continuous Function

There are several commonly used methods of defining the slippery, but extremely important, concept of a continuous function. The space of continuous functions is denoted C^0, and corresponds to the $k = 0$ case of a C-K FUNCTION.

A continuous function can be formally defined as a FUNCTION $f : X \to Y$ where the pre-image of every OPEN SET in Y is OPEN in X. More concretely, a function $f(x)$ in a single variable x is said to be continuous at point x_0 if

1. $f(x_0)$ is defined, so that x_0 is in the DOMAIN of f.
2. $\lim_{x \to x_0} f(x)$ exists for x in the DOMAIN of f.
3. $\lim_{x \to x_0} f(x) = f(x_0)$,

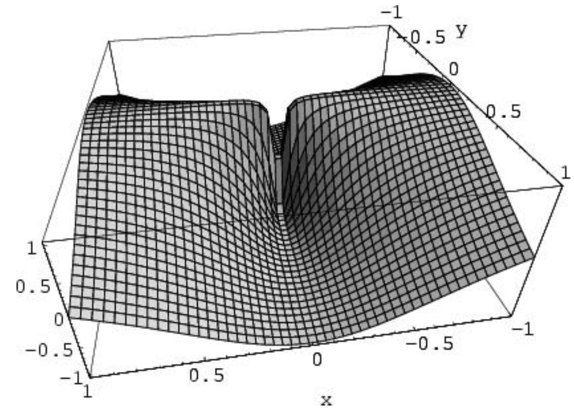
where lim denotes a LIMIT.

Many mathematicians prefer to define the continuity of a function via a so-called EPSILON-DELTA DEFINITION of a LIMIT. In this formalism, a LIMIT c of function $f(x)$ as x approaches a point x_0,

$$\lim_{x \to x_0} f(x) = c, \tag{1}$$

is defined when, given any $\epsilon > 0$, a $\delta > 0$ can be found such that for every x in some domain D and within the neighborhood of x_0 of radius δ (except possibly x_0 itself),

$$|f(x) - c| < \epsilon. \tag{2}$$



Then if x_0 is in D and

$$\lim_{x \to x_0} f(x) = f(x_0) = c, \tag{3}$$

$f(x)$ is said to be continuous at x_0.

If f is DIFFERENTIABLE at point x_0, then it is also continuous at x_0. If two functions f and g are continuous at x_0, then

1. $f + g$ is continuous at x_0.
2. $f - g$ is continuous at x_0.
3. $f \times g$ is continuous at x_0.
4. $f \div g$ is continuous at x_0 if $g(x_0) \neq 0$ and is discontinuous at x_0 if $g(x_0) = 0$.
5. $f \circ g$ is continuous at x_0, where $f \circ g$ denotes $f(g(x))$, the COMPOSITION of the functions f and g.

The notion of continuity for a function in two variables is slightly trickier, as illustrated above by the plot of the function

$$z = \frac{x^2 - y^2}{x^2 + y^2}. \tag{4}$$

This function is discontinuous at the origin, but has limit 0 along the line $x = y$, limit 1 along the X-AXIS, and limit -1 along the Y-AXIS (Kaplan 1992, p. 83).

Continuous Group

A GROUP having CONTINUOUS group operations. A continuous group is necessarily infinite, since an INFINITE GROUP just has to contain an infinite number of elements. But some infinite groups, such as the integers or rationals, are not continuous groups.

See also DISCRETE GROUP, FINITE GROUP, INFINITE GROUP

Continuous Space

A TOPOLOGICAL SPACE.

See also NET

Continuous Transformation

HOMEOMORPHISM

Continuous Vector Bundle

A continuous vector bundle is a VECTOR BUNDLE $\pi : E \to M$ with only the structure of a TOPOLOGICAL

MANIFOLD. The map π is CONTINUOUS. It has no SMOOTH STRUCTURE or METRIC.

See also BUNDLE, MANIFOLD, METRIC (BUNDLE), VECTOR BUNDLE

Continuously Differentiable Function

The space of continuously differentiable functions is denoted C^1, and corresponds to the $k = 1$ case of a C-k FUNCTION.

See also C-k FUNCTION, CONTINUOUS FUNCTION

References

Continuum

The nondenumerable set of REAL NUMBERS, denoted C. It satisfies

$$\aleph + C = C \tag{1}$$

and

$$C^r = C, \tag{2}$$

where $\aleph_0$ is ALEPH-0. It is also true that

$$\aleph_0^{\aleph_0} = C. \tag{3}$$

However,

$$C^C = F \tag{4}$$

is a SET larger than the continuum. Paradoxically, there are exactly as many points C on a LINE (or LINE SEGMENT) as in a PLANE, a 3-D SPACE, or finite HYPERSPACE, since all these SETS can be put into a ONE-TO-ONE correspondence with each other.

The CONTINUUM HYPOTHESIS, first proposed by Georg Cantor, holds that the CARDINAL NUMBER of the continuum is the same as that of ALEPH-1. The surprising truth is that this proposition is UNDECIDABLE, since neither it nor its converse contradicts the tenets of SET THEORY.

See also ALEPH-0, ALEPH-1, CONTINUUM HYPOTHESIS, DENUMERABLE SET

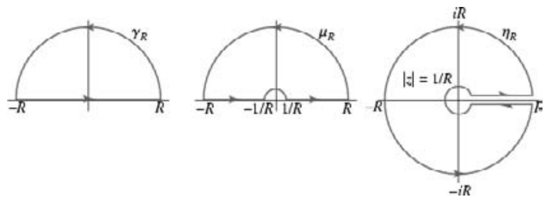
Continuum Hypothesis

Portions of this entry contributed by MATTHEW SZUDZIK

The proposal originally made by Georg Cantor that there is no infinite set with a CARDINAL NUMBER between that of the "small" infinite set of INTEGERS $\aleph_0$ and the "large" infinite set of REAL NUMBERS C (the "CONTINUUM"). Symbolically, the continuum hypothesis is that $\aleph_1 = C$.

Gödel showed that no CONTRADICTION would arise if the continuum hypothesis were added to conventional ZERMELO-FRAENKEL SET THEORY. However, using a technique called FORCING, Paul Cohen (1963, 1964) proved that no contradiction would arise if the *negation* of the continuum hypothesis was added to SET THEORY. Together, Gödel's and Cohen's results established that the validity of the continuum hypothesis depends on the version of SET THEORY being used, and is therefore UNDECIDABLE (assuming the ZERMELO-FRAENKEL AXIOMS together with the AXIOM OF CHOICE).

Conway and Guy (1996, p. 282) recount a generalized version of the continuum hypothesis originally due to Hausdorff in 1908 which is also UNDECIDABLE: is $2^{\aleph_\alpha} = \aleph_{\alpha+1}$ for every α? The continuum hypothesis follows from generalized continuum hypothesis, so $\mathrm{ZF} + \mathrm{GCH} \vdash \mathrm{CH}$.



In 2000, H. Woodin formulated a new plausible "axiom" whose adoption (in addition to the ZERMELO-FRAENKEL AXIOMS and AXIOM OF CHOICE) would imply that the Continuum Hypothesis is false. Since set theoreticians have felt for some time that the Continuum Hypothesis should be false, if Woodin's axiom proves to be particularly elegant, useful, or intuitive, it may catch on. It is interesting to compare this to a situation with Euclid's PARALLEL POSTULATE more than 300 years ago, when Wallis proposed an additional axiom that would imply the PARALLEL POSTULATE (Greenberg 1994, pp. 152–53).

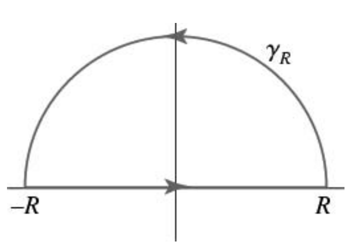
Contour

A path in the COMPLEX PLANE over which CONTOUR INTEGRATION is performed to compute a CONTOUR INTEGRAL. When choosing a contour to evaluate an integral on the REAL LINE, a contour is generally chosen based on the range of integration and the position of POLES in the COMPLEX PLANE. For example, for an integral from $-\infty$ to $+\infty$ along the real axis, the contour at left could be chosen if the function f had no POLES on the REAL LINE, and the middle contour could be chosen if it had a POLE at the origin. To perform an integral over the positive real axis from 0 to $+\infty$ for a function with a POLE at 0, the contour at right could be chosen.

See also CONTOUR INTEGRAL, CONTOUR INTEGRATION, HANKEL CONTOUR, INSIDE-OUTSIDE THEOREM, POLE, RESIDUE (COMPLEX ANALYSIS)

Contour Integral

An integral obtained by CONTOUR INTEGRATION. The particular path in the COMPLEX PLANE used to compute the integral is called a CONTOUR. Watson (1966 p. 20) uses the notation $\int^{(a+)} f(z)\,dz$ to denote the contour integral of $f(z)$ with CONTOUR encircling the point a once in a counterclockwise direction.



See also CONTOUR, CONTOUR INTEGRATION

References

Watson, G. N. *A Treatise on the Theory of Bessel Functions, 2nd ed.* Cambridge, England: Cambridge University Press, 1966.

Contour Integration

Contour integration is the process of calculating the values of a CONTOUR INTEGRAL around a given CONTOUR in the COMPLEX PLANE. As a result of a truly amazing property of HOLOMORPHIC FUNCTIONS, such integrals can be computed easily simply by summing the values of the RESIDUES *inside* the CONTOUR.

Let $P(x)$ and $Q(x)$ be POLYNOMIALS of DEGREES n and m with COEFFICIENTS $b_n, ..., b_0$ and $c_m, ..., c_0$. Take the CONTOUR in the UPPER HALF-PLANE, replace x by z, and write $z \equiv Re^{i\theta}$. Then

$$\int_{-\infty}^{\infty} \frac{P(z)\,dz}{Q(z)} = \lim_{R\to\infty} \int_{-R}^{R} \frac{P(z)\,dz}{Q(z)}. \tag{1}$$

Define a path γ_R which is straight along the REAL axis from $-R$ to R and make a circular half-arc to connect the two ends in the upper half of the COMPLEX PLANE. The RESIDUE THEOREM then gives

$$\lim_{R\to\infty} \int_{\gamma_R} \frac{P(z)\,dz}{Q(z)}$$
$$= \lim_{R\to\infty} \int_{-R}^{R} \frac{P(z)\,dz}{Q(z)} + \lim_{R\to\infty} \int_{0}^{\pi} \frac{P(Re^{i\theta})}{Q(Re^{i\theta})}\, iRe^{i\theta}\,d\theta$$
$$= 2\pi i \sum_{\Im[z]>0} \operatorname{Res}\left[\frac{P(z)}{Q(z)}\right], \tag{2}$$

where Res denotes the RESIDUES. Solving,

$$\lim_{R\to\infty} \int_{-R}^{R} \frac{P(z)\,dz}{Q(z)}$$
$$= 2\pi i \sum_{\Im[z]>0} \operatorname{Res}\frac{P(z)}{Q(z)} - \lim_{R\to\infty} \int_{0}^{\pi} \frac{P(Re^{i\theta})}{Q(Re^{i\theta})}\, iRe^{i\theta}\,d\theta$$

Define

$$I_r \equiv \lim_{R\to\infty} \int_{0}^{\pi} \frac{P(Re^{i\theta})}{Q(Re^{i\theta})}\, iRe^{i\theta}\,d\theta$$
$$= \lim_{R\to\infty} \int_{0}^{\pi} \frac{b_n(Re^{i\theta})^n + b_{n-1}(Re^{i\theta})^{n-1} + \ldots + b_0}{c_m(Re^{i\theta})^m + c_{m-1}(Re^{i\theta})^{m-1} + \ldots + c_0}\, iR\,d\theta$$
$$= \lim_{R\to\infty} \int_{0}^{\pi} \frac{b_n}{c_m}(Re^{i\theta})^{n-m} iR\,d\theta$$
$$= \lim_{R\to\infty} \int_{0}^{\pi} \frac{b_n}{c_m} R^{n+1-m} i(e^{i\theta})^{n-m}\,d\theta \tag{3}$$

and set

$$\epsilon \equiv -(n+1-m), \tag{4}$$

then equation (3) becomes

$$I_r \equiv \lim_{R\to\infty} \frac{i}{R^\epsilon} \frac{b_r}{c_m} \int_{0}^{\pi} e^{i(n-m)\theta}\,d\theta. \tag{5}$$

Now,

$$\lim_{R\to\infty} R^{-\epsilon} = 0 \tag{6}$$

for $\varepsilon > 0$. That means that for $-n-1+m \geq 1$, or $m \geq n+2$, $I_R = 0$, so

$$\int_{-\infty}^{\infty} \frac{P(z)\,dz}{Q(z)} = 2\pi i \sum_{\Im[z]>0} \operatorname{Res}\left[\frac{P(z)}{Q(z)}\right] \tag{7}$$

for $m \geq n+2$. Apply JORDAN'S LEMMA with $f(x) \equiv P(x)/Q(x)$. We must have

$$\lim_{x \to \infty} f(x) = 0, \quad (8)$$

so we require $m \geq n+1$. Then

$$\int_{-\infty}^{\infty} \frac{P(z)}{Q(z)} e^{iaz}\, dz = 2\pi i \sum_{\Im[z]>0} \operatorname{Res}\left[\frac{P(z)}{Q(z)} e^{iaz}\right] \quad (9)$$

for $m \geq n+1$.

Since this must hold separately for REAL and IMAGINARY PARTS, this result can be extended to

$$\int_{-\infty}^{\infty} \frac{P(x)}{Q(x)} \cos(ax)\, dx = 2\pi \Re\left\{\sum_{\Im[z]>0} \operatorname{Res}\left[\frac{P(z)}{Q(z)} e^{iaz}\right]\right\} \quad (10)$$

$$\int_{-\infty}^{\infty} \frac{P(x)}{Q(x)} \sin(ax)\, dx = 2\pi \Im\left\{\sum_{\Im[z]>0} \operatorname{Res}\left[\frac{P(z)}{Q(z)} e^{iaz}\right]\right\}. \quad (11)$$

It is also true that

$$\int_{-\infty}^{\infty} \frac{P(z)}{Q(z)} \ln(az)\, dz = 0. \quad (12)$$

Contractant

CONDENSATION

Contracted Cycloid

CURTATE CYCLOID

Contraction (Geometry)

An AFFINE TRANSFORMATION in which the scale is reduced.

See also EXPANSION

Contraction (Graph)

The merging of nodes in a GRAPH by eliminating segments between two nodes.

Contraction (Ideal)

When $f: A \to B$ is a ring HOMOMORPHISM and $\mathfrak{b}$ is an IDEAL in B, then $f-1(\mathfrak{b})$ is an ideal in A, called the contraction of $\mathfrak{b}$ and sometimes denoted $\mathfrak{b}^c$.

The contraction of a PRIME IDEAL is always prime. For example, consider $f: \mathbb{Z} \to \mathbb{Z}[\sqrt{2}]$. Then the contraction of $\langle\sqrt{2}\rangle$ is the ideal of even integers.

See also ALGEBRAIC NUMBER THEORY, EXTENSION (IDEAL), IDEAL, PRIME IDEAL, RING

References

Atiyah, M. F. and MacDonald, I. G. *Introduction to Commutative Algebra.* Reading, MA: Addison-Wesley, pp. 9–0, 1969.

Contraction (Tensor)

The contraction of a TENSOR is obtained by setting unlike indices equal and summing according to the EINSTEIN SUMMATION convention. Contraction reduces the RANK of a TENSOR by 2. For a second RANK TENSOR,

$$\operatorname{contr}(B'^{i}_{j}) \equiv B'^{i}_{i}$$

$$B'^{i}_{i} = \frac{\partial x'_i}{\partial x_k} \frac{\partial x_l}{\partial x'_i} B^k_l = \frac{\partial x_l}{\partial x_k} B^k_l = \delta^l_k B^k_l = B^k_k.$$

Therefore, the contraction is invariant, and must be a SCALAR. In fact, this SCALAR is known as the TRACE of a MATRIX in MATRIX theory.

Contravariant Tensor

A contravariant tensor is a TENSOR having specific transformation properties (cf., a COVARIANT TENSOR). To examine the transformation properties of a contravariant tensor, first consider a TENSOR of RANK 1 (a VECTOR)

$$d\mathbf{r} = dx_1\hat{\mathbf{x}}_1 + dx_2\hat{\mathbf{x}}_2 + dx_3\hat{\mathbf{x}}_3, \tag{1}$$

for which

$$dx'_i = \frac{\partial x'_i}{\partial x_j}\, dx_j. \tag{2}$$

Now let $A_i \equiv dx_i$, then any set of quantities A_j which transform according to

$$A'_i = \frac{\partial x'_i}{\partial x_j}\, A_j, \tag{3}$$

or, defining

$$a_{ij} \equiv \frac{\partial x'_i}{\partial x_j}, \tag{4}$$

according to

$$A'_i = a_{ij}A_j \tag{5}$$

is a contravariant tensor. Contravariant tensors are indicated with raised indices, i.e., a^μ.

COVARIANT TENSORS are a type of TENSOR with differing transformation properties, denoted a_ν. However, in 3-D CARTESIAN COORDINATES,

$$\frac{\partial x_j}{\partial x'_i} = \frac{\partial x'_i}{\partial x_j} \equiv a_{ij} \tag{6}$$

for $i, j = 1, 2, 3$, meaning that contravariant and covariant tensors are equivalent. The two types of tensors do differ in higher dimensions, however. Contravariant FOUR-VECTORS satisfy

$$a^\mu = \Lambda^\mu_\nu a^\nu, \tag{7}$$

where Λ is a LORENTZ TENSOR.

To turn a COVARIANT TENSOR a_ν into a contravariant tensor a^μ (INDEX RAISING), use the METRIC TENSOR $g^{\mu\nu}$ to write

$$g^{\mu\nu}a_\nu = a^\mu. \tag{8}$$

Covariant and contravariant indices can be used simultaneously in a MIXED TENSOR.

See also CONTRAVARIANT VECTOR, COVARIANT TENSOR, FOUR-VECTOR, INDEX RAISING, LORENTZ TENSOR, METRIC TENSOR, MIXED TENSOR, TENSOR

References

Zabczyk, J. *Mathematical Control Theory: An Introduction.* Boston, MA: Birkhäuser, 1993.

Convective Acceleration

The acceleration of an element of fluid, given by the CONVECTIVE DERIVATIVE of the VELOCITY $\mathbf{v}$,

$$\frac{D\mathbf{v}}{Dt} = \frac{\partial \mathbf{v}}{\partial t} + \mathbf{v}\cdot\nabla\mathbf{v},$$

where ∇ is the GRADIENT operator.

See also ACCELERATION, CONVECTIVE DERIVATIVE, CONVECTIVE OPERATOR

References

Batchelor, G K. *An Introduction to Fluid Dynamics.* Cambridge, England: Cambridge University Press, p. 73, 1977.

Convective Derivative

A DERIVATIVE taken with respect to a moving coordinate system, also called a LAGRANGIAN DERIVATIVE. It is given by

$$\frac{D}{Dt} = \frac{\partial}{\partial t} + \mathbf{v} \cdot \nabla,$$

where ∇ is the GRADIENT operator and $\mathbf{v}$ is the VELOCITY of the fluid. This type of derivative is especially useful in the study of fluid mechanics. When applied to $\mathbf{v}$,

$$\frac{D\mathbf{v}}{Dt} = \frac{\partial \mathbf{v}}{\partial t} + (\nabla \times \mathbf{v}) \times \mathbf{v} + \nabla(\tfrac{1}{2}\mathbf{v}^2).$$

See also CONVECTIVE OPERATOR, DERIVATIVE, VELOCITY

References

Batchelor, G K. *An Introduction to Fluid Dynamics.* Cambridge, England: Cambridge University Press, p. 73, 1977.

Convective Operator

Defined for a VECTOR FIELD $\mathbf{A}$ by $(\mathbf{A} \cdot \nabla)$, where ∇ is the GRADIENT operator.

Applied in arbitrary orthogonal 3-D coordinates to a VECTOR FIELD $\mathbf{B}$, the convective operator becomes

$$[(\mathbf{A} \cdot \nabla)\mathbf{B}]_j = \sum_{k=1}^{3} \left[\frac{A_k}{h_k} \frac{\partial B_j}{\partial q_k} + \frac{B_k}{h_k h_j} \left(A_j \frac{\partial h_j}{\partial q_k} - A_k \frac{\partial h_k}{\partial q_j} \right) \right], \quad (1)$$

where the h_is are related to the METRIC TENSORS by $h_i = \sqrt{g_{ii}}$. In CARTESIAN COORDINATES,

$$(\mathbf{A} \cdot \nabla)\mathbf{B} = \left(A_x \frac{\partial B_x}{\partial x} + A_y \frac{\partial B_x}{\partial y} + A_z \frac{\partial B_x}{\partial z} \right) \hat{\mathbf{x}} + \left(A_x \frac{\partial B_y}{\partial x} + A_y \frac{\partial K_y}{\partial y} + A_z \frac{\partial B_y}{\partial z} \right) \hat{\mathbf{y}} + \left(A_x \frac{\partial B_z}{\partial x} + A_y \frac{\partial B_z}{\partial y} + A_z \frac{\partial B_z}{\partial z} \right) \hat{\mathbf{z}}. \quad (2)$$

In CYLINDRICAL COORDINATES,

$$(\mathbf{A} \cdot \nabla)\mathbf{B} = \left(A_r \frac{\partial B_r}{\partial r} + \frac{A_\phi}{r} \frac{\partial B_r}{\partial \phi} + A_z \frac{\partial B_r}{\partial z} - \frac{A_\phi B_\phi}{r} \right) \hat{\mathbf{r}} + \left(A_r \frac{\partial B_\phi}{\partial r} + \frac{A_\phi}{r} \frac{\partial B_\phi}{\partial \phi} + A_z \frac{\partial B_\phi}{\partial z} + \frac{A_\phi B_r}{r} \right) \hat{\boldsymbol{\phi}} + \left(A_r \frac{\partial B_z}{\partial r} + \frac{A_\phi}{r} \frac{\partial B_z}{\partial \phi} + A_z \frac{\partial B_z}{\partial z} \right) \hat{\mathbf{z}}. \quad (3)$$

In SPHERICAL COORDINATES,

$$(\mathbf{A} \cdot \nabla)\mathbf{B} = \left(A_r \frac{\partial B_r}{\partial r} + \frac{A_\theta}{r} \frac{\partial B_r}{\partial \theta} + \frac{A_\phi}{r \sin\theta} \frac{\partial B_r}{\partial \phi} - \frac{A_\theta B_\theta + A_\phi B_\phi}{r} \right) \hat{\mathbf{r}} + \left(A_r \frac{\partial B_\theta}{\partial r} + \frac{A_\theta}{r} \frac{\partial B_\theta}{\partial \theta} + \frac{A_\phi}{r \sin\theta} \frac{\partial B_\theta}{\partial \phi} + \frac{A_\theta B_r}{r} - \frac{A_\phi B_\phi \cot\theta}{r} \right) \hat{\boldsymbol{\theta}} + \left(A_r \frac{\partial B_\phi}{\partial r} + \frac{A_\theta}{r} \frac{\partial B_\phi}{\partial \theta} + \frac{A_\phi}{r \sin\theta} \frac{\partial B_\phi}{\partial \phi} + \frac{A_\phi B_r}{r} + \frac{A_\phi B_\theta \cot\theta}{r} \right) \hat{\boldsymbol{\phi}}. \quad (4)$$

Convergence Acceleration

CONVERGENCE IMPROVEMENT

Convergence Improvement

The improvement of the convergence properties of a SERIES, also called CONVERGENCE ACCELERATION, such that a SERIES reaches its limit to within some accuracy with fewer terms than required before. Convergence improvement can be effected by forming a LINEAR COMBINATION with a SERIES whose sum is known. Useful sums include

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)} = 1 \quad (1)$$

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)(n+2)} = \frac{1}{4} \quad (2)$$

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)(n+2)(n+3)} = \frac{1}{18} \quad (3)$$

$$\sum_{n=1}^{\infty} \frac{1}{n(n+1)\cdots(n+p)} = \frac{1}{p \cdot p!}. \quad (4)$$

Kummer's transformation takes a convergent series

$$s = \sum_{k=0}^{\infty} a_k \quad (5)$$

and another convergent series

$$c = \sum_{k=0}^{\infty} c_k \quad (6)$$

with known c such that

$$\lim_{k\to\infty} \frac{a_k}{c_k} = \lambda \neq 0. \tag{7}$$

Then a series with more rapid convergence to the same value is given by

$$s = \lambda c + \sum_{k=0}^{\infty} \left(1 - \lambda \frac{c_k}{a_k}\right) a_k \tag{8}$$

(Abramowitz and Stegun 1972).

The EULER TRANSFORM takes a convergent alternating series

$$\sum_{k=0}^{\infty} (-1)^k a_k = a_0 - a_1 + a_2 \ldots \tag{9}$$

into a series with more rapid convergence to the same value to

$$s = \sum_{k=0}^{\infty} \frac{(-1)^k \Delta^k a_0}{2^{k+1}}, \tag{10}$$

where

$$\Delta^k a_0 = \sum_{m=0}^{k} \equiv (-1)^m \binom{k}{m} a_{k-m} \tag{11}$$

(Abramowitz and Stegun 1972; Beeler *et al.* 1972).

Given a series OF THE FORM

$$S = \sum_{n=1}^{\infty} f\left(\frac{1}{n}\right), \tag{12}$$

where $f(z)$ is an ANALYTIC at 0 and on the closed unit DISK, and

$$f(z)|_{z\to 0} = \mathcal{O}(z^2), \tag{13}$$

then the series can be rearranged to

$$S = \sum_{n=1}^{\infty} \sum_{m=2}^{\infty} f_m \left(\frac{1}{n}\right)^m$$

$$= \sum_{m=2}^{\infty} \sum_{n=1}^{\infty} f_m \left(\frac{1}{n}\right)^m = \sum_{m=2}^{\infty} f_m \zeta(m), \tag{14}$$

where

$$f(z) = \sum_{m=2}^{\infty} f_m z^m \tag{15}$$

is the MACLAURIN SERIES of f and ζ is the RIEMANN ZETA FUNCTION (Flajolet and Vardi 1996). The transformed series exhibits geometric convergence. Similarly, if $f(z)$ is ANALYTIC in $|z| \leq 1/n_0$ for some POSITIVE INTEGER n_0, then

$$S = \sum_{n=1}^{n_0-1} f\left(\frac{1}{n}\right) + \sum_{m=2}^{\infty} f_m \left[\zeta(m) - \frac{1}{1^m} - \ldots - \frac{1}{(n_0-1)^m}\right], \tag{16}$$

which converges geometrically (Flajolet and Vardi 1996). (16) can also be used to further accelerate the convergence of series (14).

Convergent

The RATIONAL NUMBER obtained by keeping only a limited number of terms in a CONTINUED FRACTION is called a convergent. For example, in the SIMPLE CONTINUED FRACTION for the GOLDEN RATIO,

$$\phi = 1 + \cfrac{1}{1 + \cfrac{1}{1 + \ldots}},$$

the convergents are

$$1,\ 1 + \frac{1}{1} = 2,\ 1 + \frac{1}{1 + \frac{1}{1}} = \frac{3}{2},\ \ldots$$

The word convergent is also used to describe a CONVERGENT SEQUENCE or CONVERGENT SERIES.

See also Continued Fraction, Convergent Sequence, Convergent Series, Partial Quotient, Simple Continued Fraction

Convergent Sequence

A sequence S_n converges to the limit S

$$\lim_{n\to\infty} S_n = S$$

if, for any $\epsilon > 0$, there exists an N such that $|S_n - S| < \epsilon$ for $n > N$. If S_n does not converge, it is said to diverge. This condition can also be written as

$$\overline{\lim_{n\to\infty}}\, S_n = \underline{\lim_{n\to\infty}}\, S_n = S.$$

Every bounded monotonic sequence converges. Every unbounded sequence diverges.

Convergent Series

The infinite series $\Sigma_{n=1}^{\infty} a_n$ is convergent if the sequence of partial sums

$$S_n = \sum_{k=1}^{n} a_k$$

is convergent. Conversely, a series is divergent if the sequence of partial sums is divergent. If Σu_k and Σv_k are convergent series, then $\Sigma(u_k + v_k)$ and $\Sigma(u_k - v_k)$ are convergent. If $c \neq 0$, then Σu_k and $c\Sigma u_k$ both converge or both diverge. Convergence and divergence are unaffected by deleting a finite number of terms from the beginning of a series. Constant terms in the denominator of a sequence can usually be deleted without affecting convergence. All but the highest power terms in polynomials can usually be deleted in both numerator and denominator of a series without affecting convergence. If a series converges absolutely, then it converges.

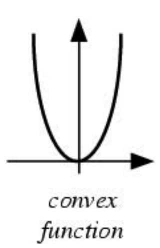
Convex



A set in Euclidean space $\mathbb{R}^d$ is a convex set if it contains *all* the line segments connecting any pair of its points. If the set does not contain all the line segments, it is called concave.

Convex Function

A function whose value at the midpoint of every interval in its domain does not exceed the average of its values at the ends of the interval. In other words, a function $f(x)$ is convex on an interval $[a, b]$ if for any two points x_1 and x_2 in $[a, b]$,

$$f[\tfrac{1}{2}(x_1 + x_2)] \leq \tfrac{1}{2}[f(x_1) + f(x_2)]$$

(Gradshteyn and Ryzhik 2000). If $f(x)$ has a second derivative in $[a, b]$, then a necessary and suffi-

CIENT condition for it to be convex on that INTERVAL is that the second DERIVATIVE $f''(x) > 0$ for all x in $[a, b]$. If the inequality above is STRICT for all x_1 and x_2, then $f(x)$ is called strictly convex. Examples of convex functions include x^p for $p \geq 1$, $x \ln x$ for $x > 0$, and $|x|$ for all x. If the sign of the inequality is reversed, the function is called CONCAVE.

Convex Hull

The convex hull of a set of points S in n-D is the INTERSECTION of all convex sets containing S. For N points $p_1, ..., p_N$, the convex hull C is then given by the expression

$$C \equiv \left\{ \sum_{j=1}^{N} \lambda_j p_j : \lambda_j \geq 0 \text{ for all } j \text{ and } \sum_{j=1}^{N} \lambda_j = 1 \right\}.$$

Computing the convex hull is a problem in COMPUTATIONAL GEOMETRY. The *indices* of the points specifying the convex hull of a set of points in two dimensions is given by the command `ConvexHull[`*pts*`]` in the *Mathematica* add-on package `DiscreteMath'ComputationalGeometry'` (which can be loaded with the command `<<DiscreteMath'`). Future versions of *Mathematica* will support n-dimensional convex hulls.

In d dimensions, the "gift wrapping" algorithm, which has complexity $\mathcal{O}(n^{\lfloor d/2 \rfloor + 1})$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION, can be used (Skiena 1997, p. 352). In 2- and 3-D, however, specialized algorithms exist with complexity $\mathcal{O}(n \ln n)$ (Skiena 1997, pp. 351–52). Yao (1981) has proved that any decision-tree algorithm for the 2-D case requires quadratic or higher-order tests, and that any algorithm using quadratic tests (which includes all currently known algorithms) cannot be done with lower complexity than $\mathcal{O}(n \ln n)$. However, it remains an open problem whether better complexity can be obtained using higher-order polynomial tests (Yao 1981). O'Rourke (1997) gives a robust 2-D implementation as well as an $\mathcal{O}(n^2)$ 3-D implementation. `Qhull` works efficiently in 2 to 8 dimensions (Barber *et al.* 1997).

The DUAL POLYHEDRON of any non-convex UNIFORM POLYHEDRON is a stellated form of the CONVEX HULL of the given polyhedron (Wenninger 1983, pp. 3– and 40).

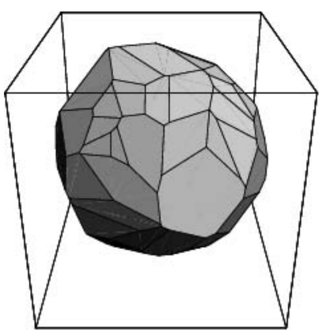
Convex Optimization Theory

The problem of maximizing a linear function over a CONVEX POLYHEDRON, also known as OPERATIONS RESEARCH or OPTIMIZATION THEORY. The general problem of convex optimization is to find the minimum of a convex (or quasiconvex) function f on a FINITE-dimensional convex body A. Methods of solution include Levin's algorithm and the method of circumscribed ELLIPSOIDS, also called the Nemirovsky-Yudin-Shor method.

References

Tokhomirov, V. M. "The Evolution of Methods of Convex Optimization." *Amer. Math. Monthly* **103**, 65–1, 1996.

Convex Polygon



A POLYGON is CONVEX if it contains *all* the LINE SEGMENTS connecting any pair of its points. Let $f(n)$ be the smallest number such that when W is a set of more than $f(n)$ points in GENERAL POSITION (with no three points COLLINEAR) in the plane, all of the VERTICES of some convex n-gon are contained in W. The answers for $n = 2$, 3, and 4 are 2, 4, and 8. It is conjectured that $f(n) = 2^{n-2}$, but only proven that

$$2^{n-2} \leq f(n) \leq \binom{2n-4}{n-2},$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

See also CONVEX POLYOMINO, CONVEX POLYHEDRON, CONVEX POLYOMINO, CONVEX POLYTOPE, HAPPY END PROBLEM, LATTICE POLYGON, POLYGON

Convex Polyhedron

A convex polyhedron can be defined algebraically as the set of solutions to a system of linear inequalities

$$\mathsf{m}\mathbf{x} \leq \mathbf{b}, \qquad (1)$$

where m is a real $s \times 3$ MATRIX and $\mathbf{b}$ is a real s-VECTOR. Although usage varies, most authors additionally require that a solution be bounded for it to define a CONVEX POLYHEDRON. An example of a convex polyhedron is illustrated above. The more simple DODECAHEDRON is given by a system with $s = 12$. Explicit examples are given in the following table.

convex polyhedron	s	m	$\mathbf{b}$
TETRAHEDRON	4	$\begin{bmatrix} 1 & 1 & 1 \\ 1 & -1 & -1 \\ -1 & 1 & -1 \\ -1 & -1 & 1 \end{bmatrix}$	$\begin{bmatrix} 2 \\ 0 \\ 0 \\ 0 \end{bmatrix}$
CUBE	6	$\begin{bmatrix} 1 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & -1 \end{bmatrix}$	$\begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$
OCTAHEDRON	8	$\begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & -1 \\ 1 & -1 & 1 \\ 1 & -1 & -1 \\ -1 & 1 & 1 \\ -1 & 1 & -1 \\ -1 & -1 & 1 \\ -1 & -1 & -1 \end{bmatrix}$	$\begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$

In general, given the MATRICES, the VERTICES (and FACES) can be found using an algorithmic procedure known as VERTEX ENUMERATION.

Geometrically, a convex polyhedron can be defined as a POLYHEDRON for which a line connecting any two (noncoplanar) points on the surface always lies in the interior of the polyhedron. The 92 convex polyhedra having only REGULAR POLYGONS as faces are called the JOHNSON SOLIDS, which include the PLATONIC SOLIDS and ARCHIMEDEAN SOLIDS. No method is known for computing the VOLUME of a general convex polyhedron (Ogilvy 1990, p. 173).

Every convex polyhedron can be represented in the plane or on the surface of a sphere by a 3-connected PLANAR GRAPH (called a POLYHEDRAL GRAPH). Conversely, by a theorem of Steinitz as restated by Grünbaum, every 3-connected PLANAR GRAPH can be realized as a convex polyhedron (Duijvestijn and Federico 1981). The numbers of vertices V, edges E, and faces F of a convex polyhedron are related by the POLYHEDRAL FORMULA

$$V + F - E = 2.$$

Convex Polyomino

A convex polyomino (sometimes called a "convex polygon") is a polyomino whose PERIMETER is equal to that of its minimal bounding box (Bousquet-Mélou *et al.* 1999). Furthermore, if it contains at least one corner of its minimal bounding box, it is said to be a DIRECTED CONVEX POLYOMINO. A COLUMN-CONVEX POLYOMINO is a self-avoiding polyomino such that the intersection of any vertical line with the polyomino has at most two connected components, and a ROW-CONVEX POLYOMINO is similarly defined.

The anisotropic perimeter and area generating function

$$G(x,\ y,\ q)=\sum_{m\geq 1}\sum_{n\geq 1}\sum_{a\geq 1}C(m,\ n,\ a)x^m y^n q^a, \tag{1}$$

where $C(m,\ n,\ a)$ is the number of polygons with $2m$ horizonal bonds, $2n$ vertical bonds, and area a is given by

$$\begin{aligned}G(x,\ y,\ q)=2&\sum_{m\geq 1}\frac{y^{m+2}}{(xq)_m^2 N(xq^{m-1})N(xq^m)}\\ &\times[T_{m+1}S(xq^m)-yT_m S(xq^{m+1})]^2\\ &+\sum_{m\geq 1}\frac{xy^m q^m (T_m)^2}{(xq)_{m-1}(xq)m},\end{aligned} \tag{2}$$

where

$$N(x)=\sum_{n\geq 0}\frac{(-1)^n x^n q^{\binom{n+1}{2}}}{(q)_n(yq)_n} \tag{3}$$

$$S(x)=\sum_{n\geq 1}\left[\frac{x^n q^n}{(yq)_n}\sum_{j=0}^{n-1}\frac{(-1)^j q^{\binom{j}{2}}}{(q)_j(yq^{j+1})_{n-j}}\right] \tag{4}$$

and $T_n(x)$ is the polynomial RECURRENCE RELATION

$$T_n(x)=2T_{n-1}(x)+(xq^{n-1}-1)T_{n-2}(x) \tag{5}$$

with $T_0(x)=1$ and $T_1(x)=1$ (Bousquet-Mélou 1992b). The first few of these polynomials are given by

$$T_2(x)=1+qx$$

$$T_3(x)=1+(2q+q^2)x$$

$$T_4(x)=1+(3q+2q^2+q^3)x+q^4x^2$$

$$T_5(x)=1+(4q+3q^2+2q^3+q^4)x+(2q^4+2q^5+q^6)x^2.$$

Expanding the generating function shows that the number of convex polyominoes having PERIMETER $2n+8$ is given by

$$(2n+11)4^n-4(2n+1)\binom{2n}{n}, \tag{6}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT (Delest and Viennot 1984, Bousquet-Mélou 1992).

This function has been computed exactly for the column-convex and directed column-convex polyominoes (Bousquet-Mélou 1996, Bousquet-Mélou *et al.* 1999). $G(1,\ 1,\ q)$ is a Q-SERIES, but becomes algebraic for column-convex polyominoes. However, $G(x,\ y,\ q)$ for column-convex polyominoes again involves Q-SERIES (Temperley 1956, Bousquet-Mélou *et al.* 1999).

$G(x,\ y)=G(x,\ y,\ 1)$ is an algebraic function of x and y (called the "fugacities") given by

$$\begin{aligned}G(x,\ y)&=\sum_{x\geq 1}\sum_{y\geq 1}C(m,\ n)x^m y^n\\ &=\frac{R(x,\ y)xy}{[\Delta(x,\ y)]^2}-\frac{4x^2y^2}{\Delta^{3/2}},\end{aligned} \tag{7}$$

where

$$\begin{aligned}R(x,\ y)=1&-3x-3y+3x^2+3y^2+5xy-x^3-y^3-x^2y\\ &-xy^2-xy(x-y)^2\end{aligned} \tag{8}$$

$$\begin{aligned}\Delta(x,\ y)&=1-2x-2y-2xy+x^2+y^2\\ &=(1-y)^2\left[1-\frac{x(2+2y-x)}{(1-y)^2}\right]\end{aligned} \tag{9}$$

(Lin and Chang 1988, Bousquet-Mélou 1992). This can be solved to explicitly give

$$\begin{aligned}C(m,\ n)=&\frac{mn-1}{m+n-2}\binom{2m+2n-4}{2m-2}\\ &-2(m+n-2)\binom{m+n-3}{m-1}\binom{m+n-3}{n-1}\end{aligned} \tag{10}$$

(Gessel 1990, Bousquet-Mélou 1992).

$G(x,\ y)$ satisfies the inversion relation

$$G(x,\ y)+y^3G(x/y,\ 1/y)=xy-x^3y\frac{\partial}{\partial x}\frac{1-x+y}{\Delta(x,\ y)}, \tag{11}$$

where

$$\Delta(x,\ y) = 1 - 2x - 2y - 2xy + x^2 + y^2$$
$$= (1-y)^2\left[1 - \frac{x(2+2y-x)}{(1-y)^2}\right] \quad (12)$$

(Lin and Chang 1988, Bousquet-Mélou *et al.* 1999).

The half-vertical perimeter and area generating function for column-convex polyominos of width 3 is given by the special case

$$H_3(y,\ q) = \frac{yq^3}{(1-yq)^4(1-yq^2)^2(1-yq^3)}$$
$$\times(y^6q^8 + 4y^5q^7 + 2y^5q^6 + y^4q^6 - y^4q^4$$
$$-4y^3q^5 - 6y^3q^4 - 4y^3q^3 - y^2q^4 + y^2q^2 + 2yq^2 + 4yq + 1) \quad (13)$$

of the general rational function (Bousquet-Mélou *et al.* 1999), which satisfies the reciprocity relation

$$H_3(1/y,\ 1/q) = -\frac{1}{yq^3}H_3(y,\ q). \quad (14)$$

The anisotropic area and perimeter generating function $G(x,\ y,\ q)$ and partial generating functions $H_m(y,\ q)$, connected by

$$G(x,\ y,\ q) = \sum_{m\geq 1} H_m(y,\ q)x^m, \quad (15)$$

satisfy the self-reciprocity and inversion relations

$$H_m(1/y,\ 1/q) = -\frac{1}{yq^m}H_m(y,\ q) \quad (16)$$

and

$$G(x,\ y,\ q) + yG(xq,\ 1/y,\ 1/q) = 0$$

(Bousquet-Mélou *et al.* 1999).

Convolution

A convolution is an integral which expresses the amount of overlap of one function $g(t)$ as it is shifted over another function $f(t)$. It therefore "blends" one function with another. For example, in synthesis imaging, the measured dirty map is a convolution of the "true" CLEAN map with the dirty beam (the Fourier transform of the sampling distribution). The convolution is sometimes also known by its German name, *faltung* ("folding").

A convolution over a finite range $[0,\ t]$ is given by

$$f(t) * g(t) \equiv \int_0^t f(\tau)g(t-\tau)\,d\tau, \quad (1)$$

where the symbol $f * g$ (occasionally also written as $f \otimes g$) denotes convolution of f and g. Convolution is more often taken over an infinite range,

$$f(t) * g(t) \equiv \int_{-\infty}^{\infty} f(\tau)g(t-\tau)\,d\tau$$
$$= \int_{-\infty}^{\infty} g(\tau)f(t-\tau)\,d\tau. \quad (2)$$

Let f, g, and h be arbitrary functions and a a constant. Convolution the satisfies the following properties,

$$f * g = g * f \quad (3)$$

$$f * (g * h) = (f * g) * h \quad (4)$$

$$f * (g + h) = (f * g) + (f * h) \quad (5)$$

(Bracewell 1999, p. 27), as well as

$$a(f*g)=(af)*g=f*(ag). \tag{6}$$

Taking the DERIVATIVE of a convolution gives

$$\frac{d}{dx}(f*g)=\frac{df}{dx}*g=f*\frac{dg}{dx}. \tag{7}$$

The AREA under a convolution is the product of areas under the factors,

$$\begin{aligned}\int_{-\infty}^{\infty}(f*g)\,dx&=\int_{-\infty}^{\infty}\left[\int_{-\infty}^{\infty}f(u)g(x-u)\,du\right]dx\\&=\int_{-\infty}^{\infty}f(u)\left[\int_{-\infty}^{\infty}g(x-u)\,dx\right]du\\&=\left[\int_{-\infty}^{\infty}f(u)\,du\right]\left[\int_{-\infty}^{\infty}g(x)\,dx\right].\end{aligned} \tag{8}$$

The horizontal CENTROIDS add

$$\langle x(f*g)\rangle=\langle xf\rangle+\langle xg\rangle, \tag{9}$$

as do the VARIANCES

$$\langle x^2(f*g)\rangle=\langle x^2f\rangle+\langle x^2g\rangle, \tag{10}$$

where

$$\langle x^nf\rangle\equiv\frac{\int_{-\infty}^{\infty}x^nf(x)\,dx}{\int_{-\infty}^{\infty}f(x)\,dx}. \tag{11}$$

There is also a definition of the convolution which arises in probability theory and is given by

$$F(t)*G(t)=\int F(t-x)\,dG(x), \tag{12}$$

where $\int F(t-x)\,dG(x)$ is a STIELTJES INTEGRAL.

Convolution Theorem

Let $f(t)$ and $g(t)$ be arbitrary functions of time t with FOURIER TRANSFORMS. Take

$$f(t)=\mathcal{F}^{-1}[F(\nu)]=\int_{-\infty}^{\infty}F(\nu)e^{2\pi i\nu t}\,d\nu \tag{1}$$

$$g(t)=\mathcal{F}^{-1}[G(\nu)]=\int_{-\infty}^{\infty}G(\nu)e^{2\pi i\nu t}\,d\nu, \tag{2}$$

where $\mathcal{F}^{-1}$ denotes the inverse FOURIER TRANSFORM (where the transform pair is defined to have constants $A=1$ and $B=-2\pi$). Then the CONVOLUTION is

$$\begin{aligned}f*g&\equiv\int_{-\infty}^{\infty}g(t')f(t-t')\,dt'\\&=\int_{-\infty}^{\infty}g(t')\left[\int_{-\infty}^{\infty}F(\nu)e^{2\pi i\nu(t-t')}\,d\nu\right]dt'.\end{aligned} \tag{3}$$

Interchange the order of integration,

$$\begin{aligned}f*g&=\int_{-\infty}^{\infty}F(\nu)\left[\int_{-\infty}^{\infty}g(t')e^{-2\pi i\nu t'}\,dt'\right]e^{2\pi i\nu t}\,d\nu\\&=\int_{-\infty}^{\infty}F(\nu)G(\nu)e^{2\pi i\nu t}\,d\nu=\mathcal{F}^{-1}[F(\nu)G(\nu)].\end{aligned} \tag{4}$$

So, applying a FOURIER TRANSFORM to each side, we have

$$\mathcal{F}[f*g]=\mathcal{F}[f]\mathcal{F}[g]. \tag{5}$$

The convolution theorem also takes the alternate forms

$$\mathcal{F}[fg]=\mathcal{F}[f]*\mathcal{F}[g] \tag{6}$$

$$\mathcal{F}^{-1}(\mathcal{F}[f]\mathcal{F}[g])=f*g \tag{7}$$

$$\mathcal{F}^{-1}(\mathcal{F}[f]*\mathcal{F}[g])=fg. \tag{8}$$

Conway Groups

The AUTOMORPHISM GROUP Co_1 of the LEECH LATTICE modulo a center of order two is called "the" Conway group. There are 15 exceptional CONJUGACY CLASSES of the Conway group. This group, combined with the GROUPS Co_2 and Co_3 obtained similarly from the LEECH LATTICE by stabilization of the 1-D and 2-D sublattices, are collectively called Conway groups. The Conway groups are SPORADIC GROUPS.

Conway Notation

CONWAY'S KNOT NOTATION, CONWAY POLYHEDRON NOTATION

Conway Polyhedron Notation

A NOTATION for POLYHEDRA which begins by specifying a "seed" polyhedron using a capital letter. The PLATONIC SOLIDS are denoted T (TETRAHEDRON), O (OCTAHEDRON), C (CUBE), I (ICOSAHEDRON), and D (DODECAHEDRON), according to their first letter. Other polyhedra include the PRISMS, Pn, ANTIPRISMS, An, and PYRAMIDS, Yn, where $n \geq 3$ specifies the number of sides of the polyhedron's base.

Operations to be performed on the polyhedron are then specified with lower-case letters preceding the capital letter.

Coordinate Chart

A coordinate chart is a way of expressing the points of a small NEIGHBORHOOD, usually on a MANIFOLD M, as coordinates in EUCLIDEAN SPACE. An example from geography is the coordinate chart given by the functions of LATITUDE and LONGITUDE. This coordinate chart is not valid on the whole globe, since it doesn't give unique coordinates at the north or south pole (which way is east from the north pole?).

Technically, a coordinate chart is a map

$$\phi:\ U \to V$$

where U is an open set in M, V is an open set in $\mathbb{R}^n$ and n is the dimension of the manifold. Often, through notational abuse, the open set U is equated with V, and calculations on the manifold are done in the coordinate chart. This technique has the drawback that it must be checked whether a change of coordinates affects the result of a calculation.

The map ϕ must be one-to-one, and in fact must be a HOMEOMORPHISM. On a SMOOTH MANIFOLD, it must be a DIFFEOMORPHISM, although if the chart defines the smooth structure then this is a tautology. Similarly, on a complex manifold, the map ϕ is holomorphic.

If there are two neighborhoods U_1 and U_2 with coordinate charts ϕ_1 and ϕ_2, the TRANSITION FUNCTION $\phi_2 \circ \phi_1^{-1}$ is WELL DEFINED since coordinate charts are one-to-one.

Coordinate Geometry

ANALYTIC GEOMETRY, CARTESIAN GEOMETRY

Coordinate System

A system for specifying points using COORDINATES measured in some specified way. The simplest coordinate system consists of coordinate axes oriented perpendicularly to each other, known as CARTESIAN COORDINATES. Depending on the type of problem under consideration, coordinate systems possessing special properties may allow particularly simple solution.

See also CURVILINEAR COORDINATES, CYCLIDIC COORDINATES, SKEW COORDINATE SYSTEM, ORTHOGONAL COORDINATE SYSTEM

Coordinates

A set of n variables which fix a geometric object. If the coordinates are distances measured along PERPENDICULAR axes, they are known as CARTESIAN COORDINATES. The study of GEOMETRY using one or more coordinate systems is known as ANALYTIC GEOMETRY.

Coordination Number

KISSING NUMBER

Copeland-Erdos Constant

The decimal 0.23571113171923... (Sloane's A033308) obtained by concatenating the PRIMES: 2, 23, 235, 2357, 235711, ... (Sloane's A019518; one of the SMARANDACHE SEQUENCES). Copeland and Erdos (1946) showed that it is a NORMAL NUMBER in base 10.

The first few digits of the CONTINUED FRACTION of the Copeland-Erdos constant are 0, 4, 4, 8, 16, 18, 5, 1, ... (Sloane's A030168). The positions of the first occurrence of n in the CONTINUED FRACTION are 8, 16, 20, 2, 7, 15, 12, 4, 17, 254, ... (Sloane's A033309). The incrementally largest terms are 4, 8, 16, 18, 58, 87, 484, ... (Sloane's A033310), which occur at positions 2, 4, 5, 6, 18, 36, 82, 89, ... (Sloane's A033311).

DE BRUIJN CONSTANT

Copson's Inequality

Let $\{a_n\}$ be a NONNEGATIVE SEQUENCE and $f(x)$ a NONNEGATIVE integrable function. Define

$$A_n = \sum_{k=1}^{n} a_k \qquad (1)$$

$$B_n = \sum_{k=n}^{\infty} a_k \qquad (2)$$

and

$$F(x) = \int_0^x f(t)\, dt \qquad (3)$$

$$G(x) = \int_x^\infty f(t)\, dt, \qquad (4)$$

and take $0 < p < 1$. For integrals,

$$\int_0^\infty \left[\frac{G(x)}{x}\right]^p dx > \left(\frac{p}{p-1}\right)^p \int_0^\infty [f(x)]^p\, dx \qquad (5)$$

(unless f is identically 0). For sums,

$$\left(1+\frac{1}{p-1}\right)B_1^p+\sum_{n=2}^{\infty}\left(\frac{B_n}{n}\right)^p > \left(\frac{p}{p-1}\right)^p \sum_{n=1}^{\infty} a_n^p \quad (6)$$

(unless all $a_n = 0$).

Copula

A function that joins univariate distribution functions to form multivariate distribution functions. A 2-D copula is a function $C: I^2 \to I$ such that

$$C(0, t) = C(t, 0) = 0$$

and

$$C(1, t) = C(t, 1) = t$$

for all $t \in I$, and

$$C(u_2, v_2) - C(u_1, v_2) - C(u_2, v_1) + C(u_1, v_1) \geq 0$$

for all $u_1, u_2, v_1, v_2 \in I$ such that $u_1 \leq u_2$ and $v_1 \leq v_2$.

See also SKLAR'S THEOREM

Cordial Graph

A GRAPH is called cordial if it is possible to label its vertices with 0s and 1s so that when the edges are labeled with the difference of the labels at their endpoints, the number of vertices (edges) labeled with ones and zeros differ at most by one. Cordial labelings were introduced by Cahit (1987) as a weakened version of GRACEFUL and HARMONIOUS.

An EULER GRAPH is not cordial if the number of its vertices is multiple of four. For example, all TREES are cordial, CYCLE GRAPHS of length n are cordial if n is not a multiple of four, COMPLETE GRAPHS on n vertices are cordial if $n < 4$, and the WHEEL GRAPH on $n+1$ vertices is cordial IFF n is not congruent to 3 modulo 4.

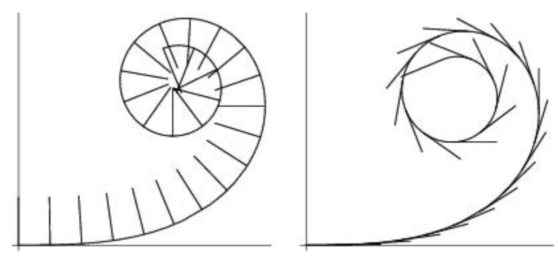
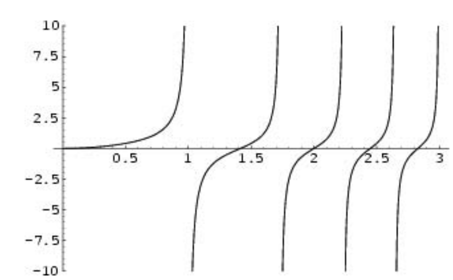
Cornu Spiral



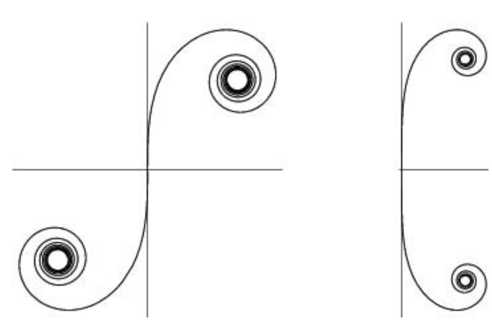
A plot in the COMPLEX PLANE of the points

$$B(t) = S(t) + iC(t), \tag{1}$$

where $S(t)$ and $C(t)$ are the FRESNEL INTEGRALS (von Seggern 1993, p. 210; Gray 1997, p. 65). The Cornu spiral is also known as the CLOTHOID or EULER'S SPIRAL. It was probably first studied by Johann Bernoulli around 1696 (Bernoulli 1967, pp. 1084–086). A Cornu spiral describes diffraction from the edge of a HALF-PLANE.



The quantities $C(t)/S(t)$ and $S(t)/C(t)$ are plotted above.



The SLOPE of the curve's TANGENT VECTOR (above right figure) is

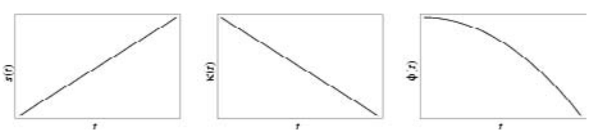
$$m_T(t) = \frac{S'(t)}{C'(t)} = \tan\left(\tfrac{1}{2}\pi t^2\right), \tag{2}$$

plotted below.

The CESÀRO EQUATION for a Cornu spiral is $\rho = c^2/s$, where ρ is the RADIUS OF CURVATURE and s the ARC LENGTH. The TORSION is $\tau = 0$.

Gray (1997) defines a generalization of the Cornu spiral given by PARAMETRIC EQUATIONS

$$x(t) = a\int_0^t \sin\left(\frac{u^{n+1}}{n+1}\right)du \quad (3)$$



$$= \frac{at^{n+2}}{(n+1)(n+2)}$$

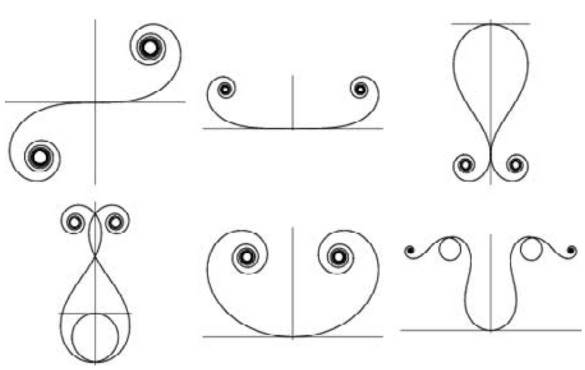
$$\times {}_1F_2\left(\frac{1}{2}+\frac{1}{2(n+1)};\ \frac{3}{2},\ \frac{3}{2}+\frac{1}{2(n+1)};\ -\frac{t^{2(n+1)}}{4(n+1)^2}\right) \quad (4)$$

$$y(t) = a\int_0^t \cos\left(\frac{u^{n+1}}{n+1}\right)du \quad (5)$$

$$= at\,{}_1F_2\left(\frac{1}{2(n+1)};\ \frac{1}{2},\ 1+\frac{1}{2(n+1)};\ -\frac{t^{2(n+1)}}{4(n+1)^2}\right), \quad (6)$$

where ${}_1F_2(a;\ b,\ c;\ x)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION.

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE of this curve are



$$s(t) = at \quad (7)$$

$$\kappa(t) = -\frac{t^n}{a} \quad (8)$$

$$\phi(t) = -\frac{t^{n+1}}{n+1}. \quad (9)$$

The CESÀRO EQUATION is

$$\kappa = -\frac{s^n}{a^{n+1}}. \quad (10)$$

Dillen (1990) describes a class of "polynomial spirals" for which the CURVATURE is a polynomial function of the ARC LENGTH. These spirals are a further generalization of the Cornu spiral. The curves plotted above correspond to $\kappa = s$, $\kappa = s^2$, $\kappa = s^2 - 2.19$, $\kappa = s^2 - 4$, $\kappa = s^2 + 1$, and $\kappa = 5s^4 - 18s^2 + 5$, respectively.

Coxeter, H. S. M. "Collineations and Correlations." §14.6 in *Introduction to Geometry, 2nd ed.* New York: Wiley, pp. 247–52, 1969.

Correlation (Statistical)

For two variables x and y, the correlation is defined by

$$\operatorname{cor}(x, y) \equiv \frac{\operatorname{cov}(x, y)}{\sigma_x \sigma_y}, \tag{1}$$

where σ_x denotes STANDARD DEVIATION and $\operatorname{cov}(x, y)$ is the COVARIANCE of these two variables. For the general case of variables x_i and x_j, where $i, j = 1, 2, \ldots, n$,

$$\operatorname{cor}(x_i, x_j) = \frac{\operatorname{cov}(x_i, y_j)}{\sqrt{V_{ii} V_{jj}}}, \tag{2}$$

where V_{ii} are elements of the COVARIANCE MATRIX. In general, a correlation gives the strength of the relationship between variables. For $i = j$,

$$\operatorname{cor}(x_i, x_i) = \frac{\operatorname{cov}(x_i, x_i)}{\sigma_i} = \frac{\sigma_{ii}}{\sigma_i} = \frac{\sigma_i^2}{\sigma_i} = \sigma_i. \tag{3}$$

The variance of any quantity is always NONNEGATIVE by definition, so

$$\operatorname{var}\left(\frac{x}{\sigma_x} + \frac{y}{\sigma_y}\right) \geq 0. \tag{4}$$

From a property of VARIANCES, the sum can be expanded

$$\operatorname{var}\left(\frac{x}{\sigma_x}\right) + \operatorname{var}\left(\frac{y}{\sigma_y}\right) + 2\operatorname{cov}\left(\frac{x}{\sigma_x}, \frac{y}{\sigma_y}\right) \geq 0 \tag{5}$$

$$\frac{1}{\sigma_x^2}\operatorname{var}(x) + \frac{1}{\sigma_y^2}\operatorname{var}(y) + \frac{2}{\sigma_x\sigma_y}\operatorname{cov}(x, y) \geq 0 \tag{6}$$

$$1 + 1 + \frac{2}{\sigma_x\sigma_y}\operatorname{cov}(x, y) = 2 + \frac{2}{\sigma_x\sigma_y}\operatorname{cov}(x, y) \geq 0. \tag{7}$$

Therefore,

$$\operatorname{cor}(x, y) = \frac{\operatorname{cov}(x, y)}{\sigma_x\sigma_y} \geq -1. \tag{8}$$

Similarly,

$$\operatorname{var}\left(\frac{x}{\sigma_x}\right) - \left(\frac{y}{\sigma_y}\right) \geq 0 \tag{9}$$

$$\operatorname{var}\left(\frac{x}{\sigma_x}\right) + \operatorname{var}\left(-\frac{y}{\sigma_y}\right) + 2\operatorname{cov}\left(\frac{x}{\sigma_x}, -\frac{y}{\sigma_y}\right) \geq 0 \tag{10}$$

$$\frac{1}{\sigma_x^2}\operatorname{var}(x) + \frac{1}{\sigma_y^2}\operatorname{var}(y) - \frac{2}{\sigma_x\sigma_y}\operatorname{cov}(x, y) \geq 0 \tag{11}$$

$$1 + 1 - \frac{2}{\sigma_x\sigma_y}\operatorname{cov}(x, y) = 2 - \frac{2}{\sigma_x\sigma_y}\operatorname{cov}(x, y) \geq 0. \tag{12}$$

Therefore,

$$\operatorname{cor}(x, y) = \frac{\operatorname{cov}(x, y)}{\sigma_x\sigma_y} \leq 1, \tag{13}$$

so $-1 \leq \operatorname{cor}(x, y) \leq 1$. For a LINEAR COMBINATION of two variables,

$$\begin{aligned}\operatorname{var}(y - bx) &= \operatorname{var}(y) + \operatorname{var}(-bx) = 2\operatorname{cov}(y, -bx)\\ &= \operatorname{var}(y) + b^2\operatorname{var}(x) - 2b\operatorname{cov}(x, y)\\ &= \sigma_y^2 + \sigma_x^2 - 2b\operatorname{cov}(x, y).\end{aligned} \tag{14}$$

Examine the cases where $\operatorname{cor}(x, y) = \pm 1$,

$$\operatorname{cor}(x, y) \equiv \frac{\operatorname{cov}(x, y)}{\sigma_x\sigma_y} = \pm 1 \tag{15}$$

$$\operatorname{var}(y - bx) = b^2\sigma_x^2 + \sigma_y^2 \mp 2b\sigma_x\sigma_y = (b\sigma_x \mp \sigma_y)^2. \tag{16}$$

The VARIANCE will be zero if $b \equiv \pm\sigma_y/\sigma_x$, which

requires that the argument of the VARIANCE is a constant. Therefore, $y - bx = a$, so $y = a + bx$. If $\operatorname{cor}(x, y) = \pm 1$, y is either perfectly correlated ($b > 0$) or perfectly anticorrelated ($b < 0$) with x.

Correlation Coefficient

The correlation coefficient is a quantity which gives the quality of a LEAST SQUARES FITTING to the original data. To define the correlation coefficient, first consider the sum of squared values ss_{xx}, ss_{xy}, and ss_{yy} of a set of n data points (x_i, y_i) about their respective means,

$$ss_{xx} \equiv \sum (x_i - \bar{x})^2 \tag{1}$$

$$= \sum x^2 - 2\bar{x} \sum x + \sum \bar{x}^2$$

$$= \sum x^2 - 2n\bar{x}^2 + n\bar{x}^2 = \sum x^2 - n\bar{x}^2 \tag{2}$$

$$ss_{yy} \equiv \sum (y_i - \bar{y})^2 \tag{3}$$

$$= \sum y^2 - 2\bar{y} \sum y + \sum \bar{y}^2$$

$$= \sum y^2 - 2n\bar{y}^2 + n\bar{y}^2 = \sum y^2 - n\bar{y}^2 \tag{4}$$

$$ss_{xy} \equiv \sum (x_i - \bar{x})(y_i - \bar{y}) \tag{5}$$

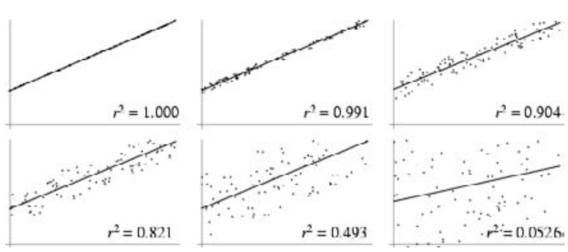
$$= \sum (x_i y_i - \bar{x} y_i - x_i \bar{y} + \bar{x}\,\bar{y})$$

$$= \sum xy - n\bar{x}\bar{y} - n\bar{x}\bar{y} + n\bar{x}\bar{y} = \sum xy - n\bar{x}\bar{y}. \tag{6}$$

For linear LEAST SQUARES FITTING, the COEFFICIENT b in

$$y = a + bx \tag{7}$$

is given by



$$b = \frac{n \sum xy - \sum x \sum y}{n \sum x^2 - \left(\sum x\right)^2} = \frac{ss_{xy}}{ss_{xx}}, \tag{8}$$

and the COEFFICIENT b' in

$$x = a' + b'y \tag{9}$$

is given by

$$b' = \frac{n \sum xy - \sum x \sum y}{n \sum y^2 - \left(\sum y\right)^2}. \tag{10}$$

The correlation coefficient r^2 (sometimes also denoted R^2) is then defined by

$$r \equiv \sqrt{bb'}$$

$$= \frac{n \sum xy - \sum x \sum y}{\sqrt{\left[n \sum x^2 - \left(\sum x\right)^2\right]\left[n \sum y^2 - \left(\sum y\right)^2\right]}}, \tag{11}$$

which can be written more simply as

$$r^2 = \frac{ss_{xy}^2}{ss_{xx} ss_{yy}}. \tag{12}$$

The correlation coefficient is also known as the PRODUCT-MOMENT COEFFICIENT OF CORRELATION or PEARSON'S CORRELATION. The correlation coefficients for linear fits to increasingly noisy data are shown above.

The correlation coefficient has an important physical interpretation. To see this, define

$$A \equiv \left[\sum x^2 - n\bar{x}^2\right]^{-1} \tag{13}$$

and denote the "expected" value for y_i as $\hat{y}_i$. Sums of $\hat{y}_i$ are then

$$\hat{y}_i = a + bx_i = \bar{y} - b\bar{x} + bx_i = \bar{x} + b(x_i - \bar{x})$$

$$= A(\bar{y} \sum x^2 - \bar{x} \sum xy + x_i \sum xy - n\bar{x}\bar{y}x_i)$$

$$= A[\bar{y} \sum x^2 + (x_i - \bar{x}) \sum xy - n\bar{x}\bar{y}x_i] \tag{14}$$

$$\sum \hat{y}_i = A(n\bar{y} \sum x^2 - n^2\bar{x}^2\bar{y}) \tag{15}$$

$$\sum \hat{y}_i^2 = A^2[n\bar{y}^2(\sum x^2)^2 - n^2\bar{x}^2\bar{y}^2(\sum x^2)$$

$$- 2n\bar{x}\bar{y}(\sum xy)(\sum x^2) + 2n^2\bar{x}^3\bar{y}(\sum xy)$$

$$+ (\sum x^2)(\sum xy)^2 - n\bar{x}^2(\sum xy)] \tag{16}$$

$$\sum y_i \hat{y}_i = A \sum [y_i \bar{y} \sum x^2 + y_i(x_i - \bar{x})$$

$$\times \sum xy - n\bar{x}\bar{y}x_i y_i]$$

$$= A[n\bar{y}^2 \sum x^2 + (\sum xy)^2 - n\bar{x}\bar{y}$$

$$\times \sum xy - n\bar{x}\bar{y}(\sum xy)]$$

$$= A[n\bar{y}^2 \sum x^2 + (\sum xy)^2 - 2n\bar{x}\bar{y} \sum xy]. \tag{17}$$

The sum of squared residuals is then

$$\mathrm{SSR} \equiv \sum (\hat{y}_i - \bar{y})^2 = \sum (\hat{y}_i^2 - 2\bar{y}\hat{y}_i + \bar{y}^2)$$

$$= A^2(\sum xy - n\bar{x}\bar{y})^2(\sum x^2 - n\bar{x}^2) = \frac{(\sum xy - n\bar{x}\bar{y})^2}{\sum x^2 - n\bar{x}^2}$$

$$= b\ ss_{xy} = \frac{ss_{xy}^2}{ss_{xx}} = ss_{yy} r^2 = b^2\ ss_{xx}, \tag{18}$$

and the sum of squared errors is

$$\begin{aligned}\mathrm{SSE} &\equiv \sum (y_i - \hat{y}_i)^2 = \sum (y_i - \bar{y} - b\bar{x} - bx_i)^2\\ &= \sum [y_i - \bar{y} - b(x_i - \bar{x})]^2\\ &= \sum (y_i - \bar{y})^2 + b^2 \sum (x_i - \bar{x})^2 - 2b\\ &\times \sum (x_i - \bar{x})(y_i - \bar{y}) = \mathrm{ss}_{yy} + b^2\, \mathrm{ss}_{xx} - 2b\mathrm{ss}_{xy}. \qquad (19)\end{aligned}$$

But

$$b = \frac{\mathrm{ss}_{xy}}{\mathrm{ss}_{xx}} \qquad (20)$$

$$r^2 = \frac{\mathrm{ss}_{xy}^2}{\mathrm{ss}_{xx}\mathrm{ss}_{yy}}, \qquad (21)$$

so

$$\mathrm{SSE} = \mathrm{ss}_{yy} + \frac{\mathrm{ss}_{xy}^2}{\mathrm{ss}_{xx}^2}\,\mathrm{ss}_{xx} - 2\,\frac{\mathrm{ss}_{xy}}{\mathrm{ss}_{xx}}\,\mathrm{ss}_{xy} \qquad (22)$$

$$= \mathrm{ss}_{yy} - \frac{\mathrm{ss}_{xy}^2}{\mathrm{ss}_{xx}} \qquad (23)$$

$$= \mathrm{ss}_{yy}\left(1 - \frac{\mathrm{ss}_{xy}^2}{\mathrm{ss}_{xx}\mathrm{ss}_{yy}}\right) \qquad (24)$$

$$= \mathrm{ss}_{yy}(1 - r^2), \qquad (25)$$

and

$$\mathrm{SSE} + \mathrm{SSR} = \mathrm{ss}_{yy}(1 - r^2) + \mathrm{ss}_{yy}r^2 = \mathrm{ss}_{yy}. \qquad (26)$$

The square of the correlation coefficient r^2 is therefore given by

$$r^2 \equiv \frac{\mathrm{SSR}}{\mathrm{ss}_{yy}} = \frac{\mathrm{ss}_{xy}^2}{\mathrm{ss}_{xx}\mathrm{ss}_{yy}} = \frac{(\sum xy - n\bar{x}\bar{y})^2}{(\sum x^2 - n\bar{x}^2)(\sum y^2 - n\bar{y}^2)}. \qquad (27)$$

In other words, r^2 is the proportion of ss_{yy} which is accounted for by the regression.

If there is complete correlation, then the lines obtained by solving for best-fit (a, b) and (a', b') coincide (since all data points lie on them), so solving (9) for y and equating to (7) gives

$$y = -\frac{a'}{b'} + \frac{x}{b'} = a + bx. \qquad (28)$$

Therefore, $a = -a'/b'$ and $b = 1/b'$, giving

$$r^2 = bb' = 1. \qquad (29)$$

The correlation coefficient is independent of both origin and scale, so

$$r(u, v) = r(x, y), \qquad (30)$$

where

$$u \equiv \frac{x - x_0}{h} \qquad (31)$$

$$v \equiv \frac{y - y_0}{h}. \qquad (32)$$

Correlation Coefficient—Gaussian Bivariate Distribution

For a Gaussian bivariate distribution, the distribution of correlation coefficients is given by

$$\begin{aligned}P(r) &= \frac{1}{\pi}(N-2)(1-r^2)^{(N-4)/2}\\ &\times (1-\rho^2)^{(N-1)/2} \int_0^\infty \frac{d\beta}{(\cosh\beta - \rho r)^{N-1}}\\ &= \frac{1}{\pi}(N-2)(1-r^2)^{(N-4)/2}(1-\rho^2)^{(N-1)/2}\sqrt{\frac{\pi}{2}}\frac{\Gamma(N-1)}{\Gamma\left(N-\frac{1}{2}\right)}\\ &\times (1-\rho r)^{-(N-3/2)}\,{}_2F_1\left(\frac{1}{2}, \frac{1}{2}, \frac{2N-1}{2}; \frac{\rho r+1}{2}\right)\\ &= \frac{(N-2)\Gamma(N-1)(1-\rho^2)^{(N-1)/2}(1-r^2)^{(N-4)/2}}{\sqrt{2\pi}\Gamma\left(N-\frac{1}{2}\right)(1-\rho r)^{N-3/2}}\\ &\times \left[1 + \frac{1}{4}\frac{\rho r+1}{2N-1} + \frac{9}{16}\frac{(\rho r+1)^2}{(2N-1)(2N+1)} + \cdots\right], \qquad (1)\end{aligned}$$

where ρ is the population correlation coefficient, ${}_2F_1(a, b; c; x)$ is a hypergeometric function, and $\Gamma(z)$ is the gamma function (Kenney and Keeping 1951, pp. 217–21). The moments are

$$\langle r\rangle = \rho - \frac{\rho(1-\rho^2)}{2n} \quad (2)$$

$$\operatorname{var}(r) = \frac{(1-\rho^2)^2}{n}\left(1+\frac{11\rho^2}{2n}+\cdots\right) \quad (3)$$

$$\gamma_1 = \frac{6\rho}{\sqrt{n}}\left(1+\frac{77\rho^2-30}{12n}+\cdots\right)$$

$$\gamma_2 = \frac{6}{n}(12\rho^2-1)+\ldots, \quad (4)$$

where $n \equiv n-1$. If the variates are uncorrelated, then $\rho = 0$ and

$$\begin{aligned}{}_2f_1\left(\frac{1}{2},\frac{1}{2},\frac{2n-1}{2};\frac{\rho r+1}{2}\right) &= {}_2F_1\left(\frac{1}{2},\frac{1}{2},\frac{2N-1}{2};\frac{1}{2}\right)\\ &= \frac{\Gamma\left(N-\frac{1}{2}\right)2^{3/2-N}\sqrt{\pi}}{\left[\Gamma\left(\frac{N}{2}\right)\right]^2},\end{aligned} \quad (5)$$

so

$$\begin{aligned}P(r) &= \frac{(N-2)\Gamma(N-1)}{\sqrt{2\pi}\Gamma\left(N-\frac{1}{2}\right)}\\ &\quad\times(1-r^2)^{(N-4)/2}\ \frac{\Gamma\left(N-\frac{1}{2}\right)2^{3/2-N}\sqrt{\pi}}{\left[\Gamma\left(\frac{N}{2}\right)\right]^2}\\ &= \frac{2^{1-N}(N-2)\Gamma(N-1)}{\left[\Gamma\left(\frac{N}{2}\right)\right]^2}(1-r^2)^{(N-4/2)}.\end{aligned} \quad (6)$$

But from the LEGENDRE DUPLICATION FORMULA,

$$\sqrt{\pi}\Gamma(N-1) = 2^{N-2}\Gamma\left(\frac{N}{2}\right)\Gamma\left(\frac{N-1}{2}\right), \quad (7)$$

so

$$\begin{aligned}P(r) &= \frac{(2^{1-N})(2^{N-2})(N-2)\Gamma\left(\frac{N}{2}\right)\Gamma\left(\frac{N-1}{2}\right)}{\sqrt{\pi}\left[\Gamma\left(\frac{N}{2}\right)\right]^2}\\ &\quad\times(1-r^2)^{(N-4)/2}\\ &= \frac{(N-2)\Gamma\left(\frac{N-1}{2}\right)}{2\sqrt{\pi}\Gamma\left(\frac{N}{2}\right)}(1-r^2)^{(N-4)/2}\\ &= \frac{1}{\sqrt{\pi}}\frac{\frac{v}{2}\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}+1\right)}(1-r^2)^{(v-2)/2}\\ &= \frac{1}{\sqrt{\pi}}\frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)}(1-r^2)^{(v-2)/2}.\end{aligned} \quad (8)$$

The uncorrelated case can be derived more simply by letting β be the true slope, so that $\eta = \alpha + \beta x$. Then

$$t \equiv (b-\beta)\frac{S_x}{S_y}\sqrt{\frac{N-2}{1-r^2}} = \frac{(b-\beta)r}{b}\sqrt{\frac{N-2}{1-r^2}} \quad (9)$$

is distributed as STUDENT'S t with $v \equiv N-2$ DEGREES OF FREEDOM. Let the population regression COEFFICIENT ρ be 0, then $\beta = 0$, so

$$t = r\sqrt{\frac{v}{1-r^2}}, \quad (10)$$

and the distribution is

$$P(t)\,dt = \frac{1}{\sqrt{v\pi}}\frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)\left(1+\frac{t^2}{v}\right)^{(v+1)/2}}\,dt. \quad (11)$$

Plugging in for t and using

$$\begin{aligned}dt &= \sqrt{v}\left[\frac{\sqrt{1-r^2}-r\left(\frac{1}{2}\right)(-2r)(1-r^2)^{-1/2}}{1-r^2}\right]dr\\ &= \sqrt{\frac{v}{1-r^2}}\left(\frac{1-r^2+r^2}{1-r^2}\right)dr = \sqrt{\frac{v}{(1-r)^3}}\,dr\end{aligned} \quad (12)$$

gives

$$\begin{aligned}P(t)\,dt &= \frac{1}{\sqrt{v\pi}}\frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)\left[1+\frac{r^2v}{(1-r^2)v}\right]^{(v+1)/2}}\sqrt{\frac{v}{(1-r)^3}}\,dr\\ &= \frac{(1-r^2)^{-3/2}}{\sqrt{\pi}}\frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)\left(\frac{1}{1-r^2}\right)^{(v+1)/2}}\,dr\end{aligned}$$

$$= \frac{1}{\sqrt{\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} (1-r^2)^{-3/2}(1-r^2)^{(\nu+1)/2}\,dr$$

$$= \frac{1}{\sqrt{\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} (1-r^2)^{(\nu-2)/2}\,dr, \qquad (13)$$

so

$$P(r) = \frac{1}{\sqrt{\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} (1-r^2)^{(\nu-2)/2} \qquad (14)$$

as before. See Bevington (1969, pp. 122–23) or Pugh and Winslow (1966, §12–). If we are interested instead in the probability that a correlation COEFFICIENT would be obtained $\geq |r|$, where r is the observed COEFFICIENT, then 392 Let $I \equiv \frac{1}{2}(\nu-2)$. For EVEN ν, the exponent I is an INTEGER so, by the BINOMIAL THEOREM,

$$(1-r^2)^I = \sum_{k=0}^{I} \binom{I}{k} (-r^2)^k \qquad (17)$$

and

$$P_c(r) = 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \times (-1)^k \frac{I!}{(I-k)!k!} \int_0^{|r|} \sum_{k=0}^{I} r'^{2k}\,dr'$$

$$= 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \times \sum_{k=0}^{I} \left[(-1)^k \frac{I!}{(I-k)!k!} \frac{|r|^{2k+1}}{2k+1}\right]. \qquad (18)$$

For ODD ν, the integral is

$$P_c(r) = 1 - 2\int_0^{|r|} P(r')\,dr'$$

$$= 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \int_0^{|r|} \left(\sqrt{1-r^2}\right)^{\nu-2}\,dr. \qquad (19)$$

Let $r \equiv \sin x$ so $dr = \cos x\,dx$, then

$$P_c(r) = 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \int_0^{\sin^{-1}|r|} \cos^{\nu-2} x \cos x\,dx$$

$$= 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} + \int_0^{\sin^{-1}|r|} \cos^{\nu-1} x\,dx. \qquad (20)$$

But ν is ODD, so $\nu - 1 \equiv 2n$ is EVEN. Therefore

$$\frac{2}{\sqrt{\pi}} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} = \frac{2}{\sqrt{\pi}} \frac{\Gamma(n+1)}{\Gamma\left(n+\frac{1}{2}\right)} = \frac{2}{\sqrt{\pi}} \frac{n!}{\frac{(2n-1)!!\sqrt{\pi}}{2^n}}$$

$$= \frac{2}{\pi} \frac{2^n n!}{\pi(2n-1)!!} = \frac{2}{\pi} \frac{(2n)!!}{(2n-1)!!}. \qquad (21)$$

Combining with the result from the COSINE INTEGRAL gives

$$P_c(r) = 1 - \frac{2}{\pi} \frac{(2n)!!(2n-1)!!}{(2n-1)!!(2n)!!} \times \left[\sin x \sum_{k=0}^{n-1} \frac{(2k)!!}{(2k+1)!!} \cos^{2k+1} x + x\right]_0^{\sin^{-1}|r|}. \qquad (22)$$

Use

$$\cos^{2k-1} x = (1-r^2)^{(2k-1)/2} = (1-r^2)^{(k-1/2)}, \qquad (23)$$

and define $J \equiv n - 1 = (\nu-3)/2$, then

$$P_c(r) = 1 - \frac{2}{\pi} \times \left[\sin^{-1}|r| + |r| \sum_{k=0}^{J} \frac{(2k)!!}{(2k+1)!!} (1-r^2)^{k+1/2}\right]. \qquad (24)$$

(In Bevington 1969, this is given incorrectly.) Combining the correct solutions

$$P_c(r) = \begin{cases} 1 - \frac{2}{\sqrt{\pi}} \frac{\Gamma[(\nu+1)/2]}{\Gamma(\nu/2)} \sum_{k=0}^{I} \left[(-1)^k \frac{I!}{(1-k)!k!} \frac{|r|^{2k+1}}{2k+1}\right] & \text{for } \nu \text{ even} \\ 1 - \frac{2}{\pi} \left[\sin^{-1}|r| + |r| \sum_{k=0}^{J} \frac{(2k)!!}{(2k+1)!!} (1-r^2)^{k+1/2}\right] & \text{for } \nu \text{ odd} \end{cases} \qquad (25)$$

If $\rho \neq 0$, a skew distribution is obtained, but the variable z defined by

$$z \equiv \tanh^{-1} r \qquad (26)$$

is approximately normal with

$$\mu_z = \tanh^{-1} \rho \tag{27}$$

$$\sigma_z^2 = \frac{1}{N-3} \tag{28}$$

(Kenney and Keeping 1962, p. 266).

Let b_j be the slope of a best-fit line, then the multiple correlation COEFFICIENT is

$$R^2 \equiv \sum_{j=1}^{n} \left(b_j \frac{s_{jy}^2}{s_y^2} \right) = \sum_{j=1}^{n} \left(b_j \frac{s_j}{s_y} r_{jy} \right), \tag{29}$$

where s_{jy} is the sample VARIANCE.

On the surface of a SPHERE,

$$r \equiv \frac{\int fg\, d\Omega}{\int f\, d\Omega \int g\, d\Omega}, \tag{30}$$

where $d\Omega$ is a differential SOLID ANGLE. This definition guarantees that $-1 < r < 1$. If f and g are expanded in REAL SPHERICAL HARMONICS,

$$f(\theta, \phi) \equiv \sum_{l=0}^{\infty} \sum_{m=0}^{l} [C_l^m Y_l^{mc}(\theta, \phi) \sin(m\phi) + S_l^m Y_l^{ms}(\theta, \phi)] \tag{31}$$

$$g(\theta,\ \phi) \equiv \sum_{t=0}^{\infty} \sum_{m=0}^{l} [A_l^m Y_l^{mc}(\theta,\ \phi) \sin(m\phi) + B_l^m Y_l^{ms}(\theta,\ \phi)]. \tag{32}$$

Then

$$r_1 = \frac{\sum_{m=0}^{l} (C_l^m A_l^m + S_l^m B_l^m)}{\sqrt{\sum_{m=0}^{l} (C_l^{m2} + S_l^{m2})} \sqrt{\sum_{m=0}^{l} (A_l^{m2} + B_l^{m2})}}. \tag{33}$$

The confidence levels are then given by

$$G_1(r) = r$$

$$G_2(r) = r\left(1 + \tfrac{1}{2} s^2\right) = \tfrac{1}{2} r(3 - r^2)$$

$$G_3(r) = r\left[1 + \tfrac{1}{2} s^2 \left(1 + \tfrac{3}{4} s^2\right)\right] = \tfrac{1}{8} r(15 - 10r^2 + 3r^4)$$

$$G_4(r) = r\left\{1 + \tfrac{1}{2} s^2 \left[1 + \tfrac{3}{4} s^2 \left(1 + \tfrac{5}{6} s^2\right)\right]\right\} = \tfrac{1}{16} r(35 - 35r^2 + 21r^4 - 5r^6),$$

where

$$s \equiv \sqrt{1 - r^2} \tag{34}$$

(Eckhardt 1984).

Correlation Dimension

Define the correlation integral as

$$C(\epsilon) \equiv \lim_{n\to\infty} \frac{1}{N^2} \sum_{\substack{i,j=1 \\ i\neq j}}^{\infty} H(\epsilon - \|x_i - x_j\|), \tag{1}$$

where H is the HEAVISIDE STEP FUNCTION. When the below limit exists, the correlation dimension is then defined as

$$D_2 \equiv d_{\text{cor}} \equiv \lim_{\epsilon, \epsilon' \to 0+} \frac{\ln\left[\frac{C(\epsilon)}{C(\epsilon')}\right]}{\ln\left(\frac{\epsilon}{\epsilon'}\right)}. \tag{2}$$

If ν is the CORRELATION EXPONENT, then

$$\lim_{\epsilon\to 0} \nu \to D_2. \tag{3}$$

It satisfies

$$d_{\text{cor}} \le d_{\text{inf}} \le d_{\text{cap}} \stackrel{?}{=} d_{\text{Lya}}. \tag{4}$$

To estimate the correlation dimension of an M-dimensional system with accuracy $(1-Q)$ requires N_{min} data points, where

$$N_{\text{min}} \ge \left[\frac{R(2-Q)}{2(1-Q)}\right]^M, \tag{5}$$

where $R \ge 1$ is the length of the "plateau region." If an ATTRACTOR exists, then an estimate of D_2 saturates above some M given by

$$M \ge 2D + 1, \tag{6}$$

which is sometimes known as the fractal Whitney embedding prevalence theorem.

Correlation Exponent

A measure ν of a STRANGE ATTRACTOR which allows the presence of CHAOS to be distinguished from random noise. It is related to the CAPACITY DIMENSION D and INFORMATION DIMENSION σ, satisfying

$$\nu \leq \sigma \leq D. \tag{1}$$

It satisfies

$$\nu \leq D_{\rm KY}, \tag{2}$$

where $D_{\rm KY}$ is the KAPLAN-YORKE DIMENSION. As the cell size goes to zero,

$$\lim_{\epsilon\to 0} \nu \to D_2, \tag{3}$$

where D_2 is the CORRELATION DIMENSION.

See also CORRELATION DIMENSION, INFORMATION DIMENSION, KAPLAN-YORKE DIMENSION

Correlation Index

Given a *curved* regression, the correlation index is defined by

$$r_c \equiv \frac{s_{y\hat{y}}}{s_y s_{\hat{y}}},$$

where s_y and $s_{\hat{y}}$ are the standard deviations of the data points y and the estimates $\hat{y}$ given by the regression line, and the quantity $s_{y\hat{y}}$ is not defined by Kenney and Keeping 1962. Then

$$r_c^2 = \frac{s_{\hat{y}}^2}{s_y^2} = 1 - \frac{s_{ey}^2}{s_y^2},$$

where s_{ey}^2 is the variance of the observed ys about the best-fitting curved line (Kenney and Keeping 1962, p. 293).

See also CORRELATION COEFFICIENT, REGRESSION

References

Kenney, J. F. and Keeping, E. S. *Mathematics of Statistics, Pt. 1, 3rd ed.* Princeton, NJ: Van Nostrand, 1962.

Correlation Integral

Consider a set of points $\mathbf{X}_i$ on an ATTRACTOR, then the correlation integral is

$$C(l) \equiv \lim_{N\to\infty} \frac{1}{N^2} f,$$

where f is the number of pairs (i, j) whose distance $|\mathbf{X}_i - \mathbf{X}_j| < l$. For small l,

$$C(l) \sim l^\nu,$$

where ν is the CORRELATION EXPONENT.

Grassberger, P. and Procaccia, I. "Measuring the Strangeness of Strange Attractors." *Physica D* **9**, 189–08, 1983.

Correlation Ratio

Let there be N_i observations of the ith phenomenon, where $i = 1, \ldots, p$ and

$$N \equiv \sum N_i \tag{1}$$

$$\bar{y}_i \equiv \frac{1}{N_i} \sum_\alpha y_{i\alpha} \tag{2}$$

$$\bar{y} \equiv \frac{1}{N} \sum_i \sum_\alpha y_{i\alpha}. \tag{3}$$

Then

$$E_{yx}^2 \equiv \frac{\sum_i N_i(\bar{y}_i - \bar{y})^2}{\sum_i \sum_\alpha (y_{i\alpha} - \bar{y})^2}. \tag{4}$$

Let η_{yx} be the population correlation ratio. If $N_i = N_j$ for $i \neq j$, then

$$f(E^2) = \frac{e^{-\lambda}(E^2)^{a-1}(1-E^2)^{b-1}\, {}_1F_1(a, b; \lambda E^2)}{B(a, b)}, \tag{5}$$

where

$$\lambda \equiv \frac{N\eta^2}{2(1-\eta^2)} \tag{6}$$

$$a \equiv \frac{n_1}{2} \tag{7}$$

$$b \equiv \frac{n_2}{2} \tag{8}$$

and ${}_1F_1(a, b; z)$ is the CONFLUENT HYPERGEOMETRIC LIMIT FUNCTION. If $\lambda = 0$, then

$$f(E^2) = \beta(a, b) \tag{9}$$

(Kenney and Keeping 1951, pp. 323–24).

Cos

COSINE

Cosecant

The function defined by $\csc x \equiv 1/\sin x$, where $\sin x$ is the SINE. The MACLAURIN SERIES of the cosecant function is

$$\csc x = \frac{1}{x} + \tfrac{1}{6}x + \tfrac{7}{360}x^3 + \tfrac{31}{15120}x^5 + \ldots + \frac{(-1)^{n+1}2(2^{2n-1}-1)B_{2n}}{(2n)!}x^{2n-1} + \ldots,$$

where B_{2n} is a BERNOULLI NUMBER.

Coset

This entry contributed by NICOLAS BRAY

For a SUBGROUP H of a GROUP G and an element x of G, define $xH$to be the set $\{xh : h \in H\}$ and Hx to be the set $\{hx : h \in H\}$. A SUBSET of G of the form xH for some $x \in G$ is said to be a LEFT COSET of H and a subset of the form Hx is said to be a RIGHT COSET of H.

For any SUBGROUP H, we can define an EQUIVALENCE RELATION $\sim$ by $x \sim y$ if $x = yh$ for some $h \in H$. The EQUIVALENCE CLASSES of this EQUIVALENCE RELATION are exactly the LEFT COSETS of H, and an element x of G is in the EQUIVALENCE CLASS xH. Thus the LEFT COSETS of H form a partition of G.

It is also true that any two LEFT COSETS of H have the same CARDINALITY, and in particular, every coset of H has the same CARDINALITY as $eH = H$, where e is the IDENTITY ELEMENT. Thus, the CARDINALITY of any LEFT COSET of H has CARDINALITY the order of H.

The same results are true of the RIGHT COSETS of G as well and, in fact, one can prove that the set of LEFT COSETS of H has the same CARDINALITY as the set of RIGHT COSETS of H.

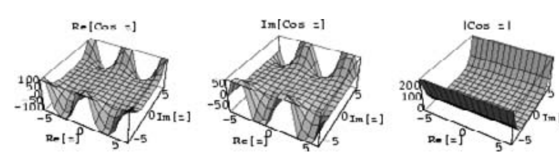
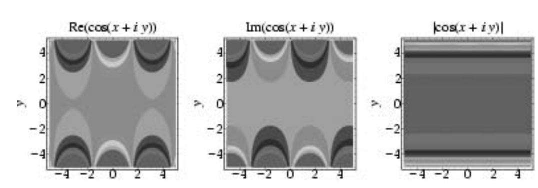
HYPERBOLIC COSINE



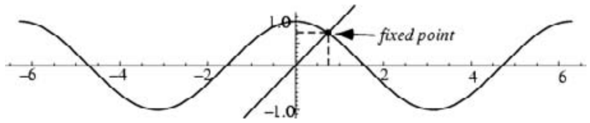
CoshIntegral



CHI

Cosine

One of the basic TRIGONOMETRIC FUNCTIONS encountered in TRIGONOMETRY. Let θ be an ANGLE measured counterclockwise from the X-AXIS along the arc of the unit CIRCLE. Then $\cos\theta$ is the horizontal coordinate of the arc endpoint. As a result of this definition, the cosine function is periodic with period 2π.



The definition of the cosine function can be extended to complex arguments z using the definition

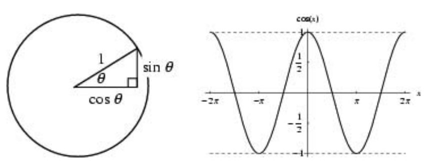
$$\cos z = \tfrac{1}{2}(e^{iz} + e^{-iz}), \tag{1}$$

where e is the base of the NATURAL LOGARITHM and i is the IMAGINARY NUMBER. A related function known as the HYPERBOLIC COSINE is similarly defined,

$$\cosh z = \tfrac{1}{2}(e^z + e^{-z}). \quad (2)$$

The cosine function has a FIXED POINT at 0.739085. The cosine function can be defined algebraically using the infinite sum

$$\cos x \equiv \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!} = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \ldots, \quad (3)$$



or the INFINITE PRODUCT

$$\cos x = \prod_{n=1}^{\infty} \left[1 - \frac{4x^2}{\pi^2(2n-1)^2}\right]. \quad (4)$$

A close approximation to $\cos(x)$ for $x \in [0, \pi/2]$ is

$$\cos\left(\frac{\pi}{2}x\right) \approx 1 - \frac{x^2}{x + (1-x)\sqrt{\frac{2-x}{3}}} \quad (5)$$

(Hardy 1959). The difference between $\cos x$ *and Hardy's approximation is plotted below.*

The cosine obeys the identity

$$\cos(n\theta) = 2\cos\theta\cos[(n-1)\theta] - \cos[(n-2)\theta] \quad (6)$$

and the MULTIPLE-ANGLE FORMULA

$$\cos(nx) = \sum_{k=0}^{n} \binom{n}{k} \cos^k x \sin^{n-k} x \cos[\tfrac{1}{2}(n-k)\pi], \quad (7)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

Summing the COSINE of a multiple angle from $n=0$ to $N-1$ can be done in closed form using

$$\sum_{n=0}^{N-1} \cos(nx) = \Re\left[\sum_{n=0}^{N-1} e^{inx}\right], \quad (8)$$

where $\Re[z]$ is the REAL PART of z. The EXPONENTIAL SUM FORMULAS give

$$\sum_{n=1}^{N} \cos(nx) = \Re\left[\frac{\sin(\frac{1}{2}Nx)}{\sin(\frac{1}{2}x)} e^{i(N+1)x/2}\right] = \frac{\sin(\frac{1}{2}Nx)}{\sin(\frac{1}{2}x)} \cos[\tfrac{1}{2}x(N+1)]. \quad (9)$$

Similarly,

$$\sum_{n=0}^{\infty} p^n \cos(nx) = \Re\left[\sum_{n=0}^{\infty} p^n e^{inx}\right], \quad (10)$$

where $|p| < 1$. The EXPONENTIAL SUM FORMULA gives

$$\sum_{n=0}^{\infty} p^n \cos(nx) = \Re\left[\frac{1 - pe^{-ix}}{1 - 2p\cos x + p^2}\right] = \frac{1 - p\cos x}{1 - 2p\cos x + p^2}. \quad (11)$$

The sum of $\cos^2(kx)$ can also be done in closed form,

$$\sum_{k=0}^{N} \cos^2(kx) = \tfrac{1}{4}\{3 + 2N + \csc x \sin[x(1+2N)]\}. \quad (12)$$

The FOURIER TRANSFORM of $\cos(2\pi k_0 x)$ is given by

$$\mathcal{F}[\cos(2\pi k_0 x)] = \int_{-\infty}^{\infty} e^{-2\pi ikx}\cos(2\pi k_0 x)\,dx = \tfrac{1}{2}[\delta(k-k_0) + \delta(k+k_0)], \quad (13)$$

where $\delta(k)$ is the DELTA FUNCTION.

Cvijovic and Klinowski (1995) note that the following series

$$C_\nu(\alpha) = \sum_{k=0}^{\infty} \frac{\cos(2k+1)\alpha}{(2k+1)^\nu} \quad (14)$$

has closed form for $\nu = 2n$,

$$C_{2n}(\alpha) = \frac{(-1)^n}{4(2n-1)!} \pi^{2n} E_{2n-1}\left(\frac{\alpha}{\pi}\right), \quad (15)$$

where $E_n(x)$ is an EULER POLYNOMIAL.

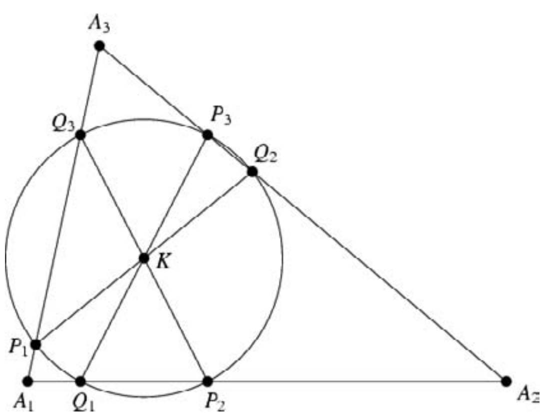
Cosine Apodization Function

The APODIZATION FUNCTION



$$A(x) = \cos\left(\frac{\pi x}{2a}\right).$$

Its FULL WIDTH AT HALF MAXIMUM is $4a/3$. Its INSTRUMENT FUNCTION is

$$I(k) = \frac{4a\,\cos(2\pi ak)}{\pi(1-16a^2k^2)}.$$

See also APODIZATION FUNCTION

Cosine Circle

Draw ANTIPARALLELS through the SYMMEDIAN POINT K. The points where these lines intersect the sides then lie on a CIRCLE, known as the cosine circle (or sometimes the second LEMOINE CIRCLE), which has center at K. The CHORDS P_2Q_3, P_3Q_1, and P_1Q_2 are proportional to the COSINES of the ANGLES of $\Delta A_1A_2A_3$, giving the circle its name. The center of the cosine circle is the CIRCUMCENTER O of ΔABC.

TRIANGLES $P_1P_2P_3$ and $\Delta A_1A_2A_3$ are directly similar, and TRIANGLES $\Delta Q_1Q_2Q_3$ and $A_1A_2A_3$ are similar. The MIQUEL POINT of $\Delta P_1P_2P_3$ is at the BROCARD POINT Ω of $\Delta P_1P_2P_3$.

The cosine circle is a special case of a TUCKER CIRCLE.

See also BROCARD POINTS, EXCOSINE CIRCLE, LEMOINE CIRCLE, MIQUEL POINT, TAYLOR CIRCLE, TUCKER CIRCLES

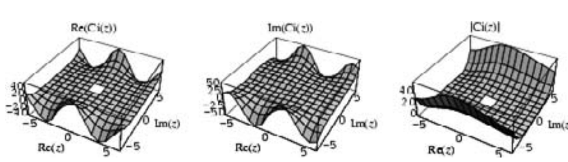
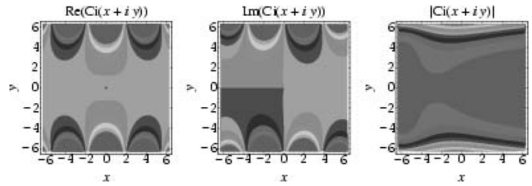
Cosine Hexagon





The closed cyclic self-intersecting hexagon formed by joining the adjacent ANTIPARALLELS in the construction of the COSINE CIRCLE. The sides of this hexagon have the property that, in addition to P_1Q_2, P_2Q_3, and P_3Q_1 being ANTIPARALLEL to A_1A_2, A_2A_3, A_1A_3, the remaining sides $P_1Q_1 \| A_2A_3$, $P_2Q_2 \| A_1A_3$, and $P_3Q_3 \| A_1A_2$. The cosine hexagon is a special case of a TUCKER HEXAGON.

See also COSINE CIRCLE, LEMOINE HEXAGON, TUCKER HEXAGON

Cosine Integral

There are (at least) three types of "cosine integrals," denoted ci(x), Ci(x), and Cin(x) :

$$\mathrm{ci}(x) \equiv -\int_x^\infty \frac{\cos t \, dt}{t} \tag{1}$$

$$= \tfrac{1}{2}[\mathrm{ei}(ix) + \mathrm{ei}(-ix)] \tag{2}$$

$$= -\tfrac{1}{2}[\mathrm{E}_1(ix) + \mathrm{E}_1(-ix)], \tag{3}$$

$$\mathrm{Ci}(x) \equiv \gamma + \ln z + \int_0^z \frac{\cos t - 1}{t} \, dt \tag{4}$$

$$\mathrm{Cin}(x) \equiv \int_0^z \frac{(1 - \cos t) \, dt}{t} \tag{5}$$

$$= -\mathrm{Ci}(x) + \ln x + \gamma. \tag{6}$$

Here, ei(x) is the EXPONENTIAL INTEGRAL, $\mathrm{E}_n(x)$ is the *En*-FUNCTION, and γ is the EULER-MASCHERONI CONSTANT. ci(x) is the function returned by the *Mathematica* command `CosIntegral[x]` and displayed above.

ci(x) has zeros at 0.616505, 3.38418, 6.42705, ... Extrema occur when

$$\mathrm{ci}'(x) = \frac{\cos x}{x} = 0, \tag{7}$$

or $\cos x = 0$, or $\pi/2$, $3\pi/2$, $5\pi/2$, ..., which are alternately maxima and minima. At these points, ci(x) equals 0.472001, –0.198408, 0.123772, ... Inflection points occur when

$$\mathrm{ci}''(x) = -\frac{\cos x}{x^2} - \frac{\sin x}{x} = 0, \tag{8}$$

which simplifies to

$$1 + x \tan x = 0, \tag{9}$$

which has solutions 2.79839, 6.12125, 9.31787, ...

To compute the integral of an EVEN power times a cosine,

$$I \equiv \int x^{2n} \cos(mx) \, dx, \tag{10}$$

use INTEGRATION BY PARTS. Let

$$u = x^{2n} \quad dv = \cos(mx) \, dx \tag{11}$$

$$du = 2nx^{2n-1} \, dx \quad v = \frac{1}{m} \sin(mx), \tag{12}$$

so

$$I = \frac{1}{m} x^{2n} \sin(mx) - \frac{2n}{m} \int x^{2n-1} \sin(mx) \, dx. \tag{13}$$

Using INTEGRATION BY PARTS again,

$$u = x^{2n-1} \quad dv = \sin(mx) \, dx \tag{14}$$

$$du = (2n-1)x^{2n-2} \, dx \quad v = -\frac{1}{m} \cos(mx), \tag{15}$$

and

$$\begin{aligned}
&\int x^{2n} \cos(mx) \, dx \\
&= \frac{1}{m} x^{2n} \sin(mx) - \frac{2n}{m} \\
&\quad \times \left[-\frac{1}{m} x^{2n-1} \cos(mx) + \frac{2n-1}{m} \int x^{2n-2} \cos(mx) \, dx \right] \\
&= \frac{1}{m} x^{2n} \sin(mx) + \frac{2n}{m^2} x^{2n-1} \cos(mx) \\
&\quad - \frac{(2n)(2n-1)}{m^2} \int x^{2n-2} \cos(mx) \, dx \\
&= \frac{1}{m} x^{2n} \sin(mx) + \frac{2n}{m^2} x^{2n-1} \cos(mx) + \ldots \\
&\quad + \frac{(2n)!}{m^{2n}} \int x^0 \cos(mx) \, dx \\
&= \frac{1}{m} x^{2n} \sin(mx) + \frac{2n}{m^2} x^{2n-1} \cos(mx) + \ldots \\
&\quad + \frac{(2n)!}{m^{2n+1}} \sin(mx) \\
&= \sin(mx) \sum_{k=0}^{n} (-1)^{k+1} \frac{(2n)!}{(2n-2k)! m^{2k+1}} x^{2n-2k} \\
&\quad + \cos(mx) \sum_{k=1}^{n} (-1)^{k+1} \frac{(2n)!}{(2k-2n-1)! m^{2k}} x^{2n-2k+1}.
\end{aligned} \tag{16}$$

Letting $k' \equiv n - k$,

$$\begin{aligned}
&\int x^{2n} \cos(mx) \, dx \\
&\quad = \sin(mx) \sum_{k=0}^{n} (-1)^{n-k+1} \frac{(2n)!}{(2k)! m^{2n-2k+1}} x^{2k} \\
&\quad + \cos(mx) \sum_{k=0}^{n-1} (-1)^{n-k+1} \frac{(2n)!}{(2k-1)! m^{2n-2k}} x^{2k+1}
\end{aligned}$$

$$= (-1)^{n+1}(2n)!\left[\sin(mx)\sum_{k=0}^{n-1}\frac{(-1)^k}{(2k)!m^{2n-2k+1}}\,x^{2k}\right.$$

$$\left.+\cos(mx)\sum_{k=1}^{n}\frac{(-1)^{k+1}}{(2k-3)!m^{2n-2k+2}}\,x^{2k+1}\right]. \tag{17}$$

To find a closed form for an integral power of a cosine function,

$$I \equiv \int \cos^m x\,dx, \tag{18}$$

perform an INTEGRATION BY PARTS so that

$$u = \cos^{m-1} x \quad dv = \cos x\,dx \tag{19}$$

$$du = -(m-1)\cos^{m-2} x \sin x\,dx \quad v = \sin x. \tag{20}$$

Therefore

$$I = \sin x \cos^{m-1} x + (m-1)\int \cos^{m-2} x \sin^2 x\,dx$$
$$= \sin x \cos^{m-1} x + (m-1)$$
$$\times \left[\int \cos^{m-2} x\,dx - \int \cos^m x\,dx\right]$$
$$= \sin x \cos^{m-1} x + (m-1)\left[\int \cos^{m-2} x\,dx - I\right], \tag{21}$$

so

$$I[1+(m-1)]$$
$$= \sin x \cos^{m-1} x + (m-1)\int \cos^{m-2} x\,dx \tag{22}$$

$$I = \int \cos^m x\,dx$$
$$= \frac{\sin x \cos^{m-1} x}{m} + \frac{m-1}{m}\int \cos^{m-2} x\,dx. \tag{23}$$

Now, if m is EVEN so $m \equiv 2n$, then

$$\int \cos^{2n} x\,dx = \frac{\sin x \cos^{2n-1} x}{2n} + \frac{2n-1}{2n}\int \cos^{2n-2} x\,dx$$
$$= \frac{\sin x \cos^{2n-1} x}{2n}$$
$$+ \tfrac{2n-1}{2n}\left[\frac{\sin x \cos^{2n-3} x}{2n-2} + \frac{2n-3}{2n-2}\int \cos^{2n-4} x\,dx\right]$$
$$= \sin x\left[\frac{1}{2n}\cos^{2n-1} x + \frac{2n-1}{(2n)(2n-2)}\cos^{2n-3} x\right]$$
$$+ \frac{(2n-1)(2n-3)}{(2n)(2n-2)}\int \cos^{2n-4} x\,dx$$
$$= \sin x\left[\frac{1}{2n}\cos^{2n-1} x + \frac{2n-1}{(2n)(2n-2)}\cos^{2n-3} x + \ldots\right]$$
$$+ \frac{(2n-1)(2n-3)\cdots 1}{(2n)(2n-2)\cdots 2}\int \cos^0 x\,dx$$
$$= \sin x \sum_{k=1}^{n}\frac{(2n-2k)!!}{(2n)!!}\,\tfrac{(2n-1)!!}{(2n-2k+1)!!}\cos^{2n-2k+1} x$$
$$+ \frac{(2n-1)!!}{(2n)!!}\,x. \tag{24}$$

Now let $k' \equiv n-k+1$, so $n-k = k'-1$,

$$\int \cos^{2n} x\,dx$$
$$= \sin x \sum_{k=1}^{n}\frac{(2k-2)!!}{(2n)!!}\,\frac{(2n-1)!!}{(2k-1)!!}\cos^{2k-1} x$$
$$+ \frac{(2n-1)!!}{(2n)!!}\,x$$
$$= \frac{(2n-1)!!}{(2n)!!}$$
$$\times \left[\sin x \sum_{k=0}^{n-1}\frac{(2k)!!}{(2k+1)!!}\cos^{2k+1} x + x\right]. \tag{25}$$

Now if m is ODD so $m \equiv 2n+1$, then

$$\int \cos^{2n+1} x\,dx = \frac{\sin x \cos^{2n} x}{2n+1} + \frac{2n}{2n+1}\int \cos^{2n-1} x\,dx$$
$$= \frac{\sin x \cos^{2n} x}{2n+1} + \frac{2n}{2n+1}$$
$$\times \left[\frac{\sin x \cos^{2n-2} x}{2n-1} + \frac{2n-2}{2n-1}\int \cos^{2n-3} x\,dx\right]$$
$$= \sin x\left[\frac{1}{2n+1}\cos^{2n} x + \frac{2n}{(2n+1)(2n-1)}\cos^{2n-2} x\right]$$
$$+ \frac{(2n)(2n-2)}{(2n+1)(2n-1)}\int \cos^{2n-3} x\,dx$$

$$= \sin x \left[\frac{1}{2n+1} \cos^{2n} x + \frac{2n}{(2n+1)(2n-1)} \cos^{2n-2} x + \ldots \right] + \frac{(2n)(2n-2)\cdots 2}{(2n+1)(2n-1)\cdots 3} \int \cos x \, dx$$

$$= \sin x \sum_{k=0}^{n} \frac{(2n-2k-1)!!}{(2n+1)!!} \frac{(2n)!!}{(2n-2k)!!} \cos^{2n-2k} x. \tag{26}$$

Now let $k' \equiv n - k$,

$$\int \cos^{2n} x \, dx = \frac{(2n)!!}{(2n+1)!!} \sin x \sum_{k=0}^{n} \frac{(2k-1)!!}{(2k)!!} \cos^{2k} x. \tag{27}$$

The general result is then

$$\int \cos^m x \, dx = \begin{cases} \frac{(2n-1)!!}{(2n)!!} \left[\sin x \sum_{k=0}^{n-1} \frac{(2k)!!}{(2k+1)!!} \cos^{2k+1} x + x \right] & \text{for } m = 2n \\ \frac{(2n)!!}{(2n+1)!!} \sin x \sum_{k=0}^{n} \frac{(2k-1)!!}{(2k)!!} \cos^{2k} x & \text{for } m = 2n+1. \end{cases} \tag{28}$$

The infinite integral of a cosine times a Gaussian can also be done in closed form,

$$\int_{-\infty}^{\infty} e^{-ax^2} \cos(kx) \, dx = \sqrt{\frac{\pi}{a}} e^{-k^2/4a}. \tag{29}$$

Cosmological Theorem

There exists an INTEGER N such that every string in the LOOK AND SAY SEQUENCE "decays" in at most N days to a compound of "common" and "transuranic elements."

The table below gives the periodic table of atoms associated with the LOOK AND SAY SEQUENCE as named by Conway (1987). The "abundance" is the average number of occurrences for long strings out of every million atoms. The asymptotic abundances are zero for transuranic elements, and 27.246... for arsenic (As), the next rarest element. The most common element is hydrogen (H), having an abundance of 91,970.383.... The starting element is U, represented by the string "3," and subsequent terms are those giving a description of the current term: one three (13); one one, one three (1113); three ones, one three (3113), etc.

Abundance	n	E_n	E_n is the derivate of E_{n+1}

Costa Minimal Surface

A COMPLETE MINIMAL EMBEDDABLE SURFACE of finite topology (i.e., it has no BOUNDARY and does not intersect itself). Until this surface was discovered by Costa (1984), the only other known complete minimal embeddable surfaces in $\mathbb{R}^3$ with no self-intersections were the PLANE, CATENOID, and HELICOID. The plane is genus 0 and the catenoid and the helicoid are genus 0 with two punctures, but the Costa minimal surface is genus 1 with three punctures (Schwalbe and Wagon 1999). In addition, and rather amazingly, the Costa surface belongs to the D_4 DIHEDRAL GROUP of symmetries. An animation by S. Dickson illustrates the homotopy of the TORUS into a Costa surface (Wolfram Research).

As discovered by Gray (Ferguson *et al.* 1996, Gray 1997), the Costa surface can be represented parametrically explicitly by

$$x = \tfrac{1}{2}\,\Re\left\{-\zeta(u+iv) + \pi u + \frac{\pi^2}{4e_1} + \frac{\pi}{2e_1}\left[\zeta(u+iv-\tfrac{1}{2}) - \zeta(u+iv-\tfrac{1}{2}i)\right]\right\}$$

$$y = \tfrac{1}{2}\,\Re\left\{-i\zeta(u+iv) + \pi v + \frac{\pi^2}{4e_1} - \frac{\pi}{2e_1}\left[i\zeta(u+iv-\tfrac{1}{2}) - i\zeta(u+iv-\tfrac{1}{2}i)\right]\right\}$$

$$z = \tfrac{1}{4}\sqrt{2\pi}\,\ln\left|\frac{\wp(u+iv)-e_1}{\wp(u+iv)+e_1}\right|,$$

where $\zeta(z)$ is the WEIERSTRASS ZETA FUNCTION, $\wp(g_2, g_3; z)$ is the WEIERSTRASS ELLIPTIC FUNCTION with $(g_2, g_3) = (189.072772\ldots,\ 0)$ the invariants corresponding to the half-periods 1/2 and $i/2$, and first root

$$e_1 = \wp(\tfrac{1}{2};\ 0,\ g_3) = \wp(\tfrac{1}{2}|\tfrac{1}{2},\ \tfrac{1}{2}i) \approx 6.87519,$$

where $\wp(z;\ g_2,\ g_3) = \wp(z|\omega_1,\ \omega_2)$ is the WEIERSTRASS ELLIPTIC FUNCTION.

COSTA MINIMAL SURFACE

Cosymmedian Triangles

Extend the SYMMEDIANS of a TRIANGLE $\Delta A_1A_2A_3$ to meet the CIRCUMCIRCLE at P_1, P_2, P_3. Then the SYMMEDIAN POINT K of $\Delta A_1A_2A_3$ is also the SYMMEDIAN POINT of $\Delta P_1P_2P_3$. The TRIANGLES $\Delta A_1A_2A_3$ and $\Delta P_1P_2P_3$ are cosymmedian triangles, and have the same BROCARD CIRCLE, second BROCARD TRIANGLE, BROCARD ANGLE, BROCARD POINTS, and CIRCUMCIRCLE.

See also BROCARD ANGLE, BROCARD CIRCLE, BROCARD POINTS, BROCARD TRIANGLES, CIRCUMCIRCLE, COMEDIAN TRIANGLES, SYMMEDIAN, SYMMEDIAN POINT

Cot

COTANGENT

Cotangent

The function defined by $\cot x \equiv 1/\tan x$, where $\tan x$ is the TANGENT. The notations ctn x (Erdélyi *et al.* 1981, p. 7) and ctg x (Gradshteyn and Ryzhik 2000, p. xxix) are sometimes used in place of $\cot x$.

The MACLAURIN SERIES for $\cot x$ is

$$\cot x = \frac{1}{x} - \tfrac{1}{3}x - \tfrac{1}{45}x^3 - \tfrac{2}{945}x^5 - \tfrac{1}{4725}x^7 - \ldots$$

$$- \frac{(-1)^{n+1}2^{2n}B_{2n}}{(2n)!} - \ldots,$$

where B_n is a BERNOULLI NUMBER.

$$\pi\cot(\pi x) = \frac{1}{x} + 2x\sum_{n=1}^{\infty}\frac{1}{x^2 - n^2}.$$

It is known that, for $n \geq 3$, $\cot(\pi/n)$ is rational only for $n = 4$.

Cotangent Bundle

The cotangent bundle of a MANIFOLD is similar to the TANGENT BUNDLE, except that it is the set (x, f) where $x \in M$ and f is a dual vector in the TANGENT SPACE to $x \in M$. The cotangent bundle is denoted T^*M.

See also TANGENT BUNDLE

Cotes Circle Property

$$x^{2n} + 1 = \left[x^2 - 2x\cos\left(\frac{\pi}{2n}\right) + 1\right] \times \left[x^2 - 2x\cos\left(\frac{3\pi}{2n}\right) + 1\right] \times \cdots \times \left[x^2 - 2x\cos\left(\frac{(2n-1)\pi}{2n}\right) + 1\right].$$

Coulomb Wave Function

A special case of the CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND. It gives the solution to the radial Schrödinger equation in the Coulomb potential $(1/r)$ of a point nucleus

$$\frac{d^2W}{d\rho^2}+\left[1-\frac{2\eta}{\rho}-\frac{L(L+1)}{\rho^2}\right]W=0 \tag{1}$$

(Abramowitz and Stegun 1972; Zwillinger 1997, p. 122). The complete solution is

$$W=C_1F_L(\eta,\ \rho)+C_2G_L(\eta,\ \rho). \tag{2}$$

The Coulomb function of the first kind is

$$F_L(\eta,\ \rho)=C_L(\eta)\rho^{L+1}e^{-ip}\ {}_1F_1(L+1-i\eta;\ 2L+2;\ 2i\rho), \tag{3}$$

where

$$C_L(\eta)\equiv\frac{2^Le^{-\pi\eta/2}|\Gamma(L+1+i\eta)|}{\Gamma(2L+2)}, \tag{4}$$

${}_1F_1(a;\ b;\ z)$ is the CONFLUENT HYPERGEOMETRIC FUNCTION, $\Gamma(z)$ is the GAMMA FUNCTION, and the Coulomb function of the second kind is

$$G_L(\eta,\ \rho)=\frac{2\eta}{C_0^2(\eta)}F_L(\eta,\ \rho)\left[\ln(2\rho)+\frac{q_L(\eta)}{p_L(\eta)}\right]+\frac{1}{(2L+1)C_L(\eta)}\ \rho^{-L}\sum_{K=-L}^{\infty}a_k^L(\eta)\rho^{K+L}, \tag{5}$$

where q_L, p_L, and a_k^L are defined in Abramowitz and Stegun (1972, p. 538).

Count

The largest n such that $|z_n|<4$ in a MANDELBROT SET. Points of different count are often assigned different colors.

Countable Additivity Probability Axiom

For a COUNTABLE SET of n disjoint events E_1, E_2, ..., E_n

$$P\left(\bigcup_{i=1}^{n}E_i\right)=\sum_{i=1}^{n}P(E_i).$$

See also COUNTABLE SET

Countable Set

A SET which is either FINITE or DENUMERABLE. However, some author (Ciesielski 1997, p. 64) use the definition "equipollent to the finite ordinals," commonly used to define a DENUMERABLE SET, to define a countable set.

See also ALEPH-0, ALEPH-1, COUNTABLY INFINITE, DENUMERABLE SET, FINITE, INFINITE, UNCOUNTABLY INFINITE

Countable Space

FIRST-COUNTABLE SPACE

Countably Infinite

Any SET which can be put in a ONE-TO-ONE correspondence with the NATURAL NUMBERS (or INTEGERS) so that a prescription can be given for identifying its members one at a time is called a countably infinite (or denumerably infinite) set. Once one countable set S is given, any other set which can be put into a ONE-TO-ONE correspondence with S is also countable. Countably infinite sets have CARDINAL NUMBER ALEPH-0.

Examples of countable sets include the INTEGERS, ALGEBRAIC NUMBERS, and RATIONAL NUMBERS. Georg Cantor showed that the number of REAL NUMBERS is

rigorously larger than a countably infinite set, and the postulate that this number, the so-called "CONTINUUM," is equal to ALEPH-1 is called the CONTINUUM HYPOTHESIS. Examples of nondenumerable sets include the REAL, COMPLEX, IRRATIONAL, and TRANSCENDENTAL NUMBERS.

Counterfeit Coin Problem

WEIGHING

Counting Generalized Principle

If r experiments are performed with n_i possible outcomes for each experiment $i = 1, 2, \ldots, r$, then there are a total of $\prod_{i=1}^{r} n_i$ possible outcomes.

Counting Number

A POSITIVE INTEGER: 1, 2, 3, 4, ... (Sloane's A000027), also called a NATURAL NUMBER. However, zero (0) is sometimes also included in the list of counting numbers. Due to lack of standard terminology, the following terms are recommended in preference to "counting number," "NATURAL NUMBER," and "WHOLE NUMBER."

set	name	symbol
..., -2, -1, 0, 1, 2, ...	INTEGERS	Z
1, 2, 3, 4, ...	POSITIVE INTEGERS	Z+
0, 1, 2, 3, 4, ...	NONNEGATIVE INTEGERS	Z*
0, -1, -2, -3, -4, ...	NONPOSITIVE INTEGERS	
-1, -2, -3, -4, ...	NEGATIVE INTEGERS	Z-

See also NATURAL NUMBER, WHOLE NUMBER, Z, Z-, Z+, Z*

Coupon Collector's Problem

Let n objects be picked repeatedly with probability p_i that object i is picked on a given try, with

$$\sum_i p_i = 1.$$

Find the earliest time at which all n objects have been picked at least once.

References

Hildebrand, M. V. "The Birthday Problem." *Amer. Math. Monthly* **100**, 643, 1993.

Cousin Primes

Pairs of PRIMES OF THE FORM $(p, p+4)$ are called cousin primes. The first few are (3, 7), (7, 11), (13, 17), (19, 23), (37, 41), (43, 47), (67, 71), ... (Sloane's A023200 and A046132). According to the first FIRST HARDY-LITTLEWOOD CONJECTURE, the cousin primes have the same asymptotic density as the TWIN PRIMES,

$$P_x(p, p+4) \sim 2 \prod_{p \geq 3} \frac{p(p-2)}{(p-1)^2} \int_2^x \frac{dx'}{(\ln x')^2}$$

$$= 1.320323632 \int_2^x \frac{dx'}{(\ln x')^2}$$

where $\prod_2 = 1.320323632$ is the TWIN PRIMES CONSTANT.

An analogy to BRUN'S CONSTANT, the constant

$$B_4 \equiv (\tfrac{1}{7} + \tfrac{1}{11}) + (\tfrac{1}{13} + \tfrac{1}{17}) + (\tfrac{1}{19} + \tfrac{1}{23}) + (\tfrac{1}{37} + \tfrac{1}{41}) + \ldots,$$

(omitting the initial term $1/3 + 1/7$) can be defined. Using cousin primes up to 2^{42}, the value of B_4 is estimated as

$$B_4 \approx 1.1970449$$

(Wolf 1996).

See also BRUN'S CONSTANT, PRIME CONSTELLATION, SEXY PRIMES, TWIN PRIMES, TWIN PRIMES CONSTANT

Covariance

Given n sets of variates denoted $\{x_1\}, \ldots, \{x_n\}$, the covariance $\sigma_{ij} \equiv \mathrm{cov}(x_i, x_j)$ of x_i and x_j is defined by

$$\mathrm{cov}(x_i, x_j) \equiv \langle (x_i - \mu_i)(x_j - \mu_j) \rangle \quad (1)$$

$$= \langle x_i x_j \rangle - \langle x_i \rangle \langle x_j \rangle, \quad (2)$$

where $\mu_i = \langle x_i \rangle$ and $\mu_j = \langle x_j \rangle$ are the MEANS of x_i and x_j, respectively. The matrix (V_{ij}) of the quantities

$V_{ij} = \text{cov}(x_i, x_j)$ is called the COVARIANCE MATRIX. In the special case $i = j$,

$$\text{cov}(x_i, x_i) = \langle x_i^2 \rangle - \langle x_i \rangle^2 = \sigma_i^2, \quad (3)$$

giving the usual VARIANCE $\sigma_{ii} = \sigma_i^2 = \text{var}(x_i)$, .
The covariance of two variates x_i and x_j provides a measure of how strongly correlated these variables are, and the derived quantity

$$\text{cor}(x_i, x_j) \equiv \frac{\text{cov}(x_i, x_j)}{\sigma_i \sigma_j}, \quad (4)$$

where σ_i, σ_j are the STANDARD DEVIATIONS, is called CORRELATION of x_i and x_j. The covariance is symmetric since

$$\text{cov}(x, y) = \text{cov}(y, x). \quad (5)$$

For two variables, the covariance is related to the VARIANCE by

$$\text{var}(x + y) = \text{var}(x) + \text{var}(y) + 2\ \text{cov}(x, y). \quad (6)$$

For two independent variates $x = x_i$ and $y = x_j$,

$$\text{cov}(x, y) = \langle xy \rangle - \mu_x \mu_y = \langle x \rangle \langle y \rangle - \mu_x \mu_y = 0, \quad (7)$$

so the covariance is zero. However, if the variables are correlated in some way, then their covariance will be NONZERO. In fact, if $\text{cov}(x, y) > 0$, then y tends to increase as x increases. If $\text{cov}(x, y) < 0$, then y tends to decrease as x increases.

The covariance obeys the identity

$$\begin{aligned} \text{cov}(x + z, y) &= \langle (x + z)y - (x + z)\langle y \rangle \rangle \\ &= \langle xy \rangle + \langle zy \rangle - (\langle x \rangle + \langle z \rangle)\langle y \rangle \\ &= \langle xy \rangle - \langle x \rangle \langle y \rangle + \langle zy \rangle - \langle z \rangle \langle y \rangle \\ &= \text{cov}(x, y) + \text{cov}(z, y). \end{aligned} \quad (8)$$

By induction, it therefore follows that

$$\text{cov}\left(\sum_{i=1}^n x_i, y \right) = \sum_{i=1}^n \text{cov}(x_i, y) \quad (9)$$

$$\text{cov}\left(\sum_{i=1}^n x_i, \sum_{j=1}^m y_j \right) = \sum_{i=1}^n \text{cov}\left(x_i \sum_{j=1}^m y_j \right) \quad (10)$$

$$= \sum_{i=1}^n \text{cov}\left(\sum_{j=1}^m y_j, x_i \right) \quad (11)$$

$$= \sum_{i=1}^n \sum_{j=1}^m \text{cov}(y_j, x_i) \quad (12)$$

$$= \sum_{i=1}^n \sum_{j=1}^n \text{cov}(x_i, y_j). \quad (13)$$

See also CORRELATION (STATISTICAL), COVARIANCE MATRIX, VARIANCE

Covariance Matrix

Given n sets of variates denoted $\{x_1\}, \ldots, \{x_n\}$, the first-order covariance matrix is defined by

$$V_{ij} = \text{cov}(x_i, x_j) \equiv \langle (x_i - \mu_i)(x_j - \mu_j) \rangle,$$

where μ_i is the MEAN. Higher order matrices are given by

$$V_{ij}^{mn} = \langle (x_i - \mu_i)^m (x_j - \mu_j)^n \rangle.$$

An individual matrix element $V_{ij} = \text{cov}(x_i, x_j)$ is called the COVARIANCE of x_i and x_j.

See also CORRELATION (STATISTICAL), COVARIANCE, ERROR PROPAGATION, VARIANCE

Covariant Derivative

The covariant derivative of a CONTRAVARIANT TENSOR A^a (also called the "semicolon derivative" since its symbol is a semicolon) is given by

$$\nabla \cdot \mathbf{A} \equiv A^a{}_{;b} = A^a{}_{,b} + \Gamma^a_{bk} A^k, \quad (1)$$

where $A^k_{,k}$ is a COMMA DERIVATIVE and $\nabla \cdot$ is a generalization of the symbol commonly used to denote the DIVERGENCE of a vector function in 3-D, Γ^k_{ij} is a CONNECTION COEFFICIENT, and EINSTEIN SUMMATION has been used in the last term. The covariant derivative of a COVARIANT TENSOR A_a is

$$A_{a;b} = \frac{1}{g^{bb}} \frac{\partial A_a}{\partial x_b} - \Gamma^k_{ab} A_k, \quad (2)$$

Schmutzer (1968, p. 72) uses the older notation $A^j{}_{||k}$ or $A_{j||k}$.

Covariant Tensor

A covariant tensor is a TENSOR having specific transformation properties (cf., a CONTRAVARIANT TENSOR). To examine the transformation properties of a covariant tensor, first consider the GRADIENT

$$\nabla \phi = \frac{\partial \phi}{\partial x_1} \hat{\mathbf{x}}_1 + \frac{\partial \phi}{\partial x_2} \hat{\mathbf{x}}_2 + \frac{\partial \phi}{\partial x_3} \hat{\mathbf{x}}_3, \quad (1)$$

for which

$$\frac{\partial \phi'}{\partial x_i'} = \frac{\partial \phi}{\partial x_j}\frac{\partial x_j}{\partial x_i'}, \qquad (2)$$

where $\phi(x_1, x_2, x_3) = \phi'(x_1', x_2', x_3')$. Now let

$$A_i \equiv \frac{\partial \phi}{\partial x_i}, \qquad (3)$$

then any set of quantities A_j which transform according to

$$A_i' = \frac{\partial x_j}{\partial x_i'} A_j \qquad (4)$$

or, defining

$$a_{ij} \equiv \frac{\partial x_j}{\partial x_i'}, \qquad (5)$$

according to

$$A_i' = a_{ij} A_j \qquad (6)$$

is a covariant tensor. Covariant tensors are indicated with lowered indices, i.e., a_μ.

CONTRAVARIANT TENSORS are a type of TENSOR with differing transformation properties, denoted a^ν. However, in 3-D CARTESIAN COORDINATES,

$$\frac{\partial x_j}{\partial x_i'} = \frac{\partial x_i'}{\partial x_j} \equiv a_{ij} \qquad (7)$$

for $i, j = 1, 2, 3$, meaning that contravariant and covariant tensors are equivalent. The two types of tensors do differ in higher dimensions, however. Covariant FOUR-VECTORS satisfy

$$a_\mu = \Lambda_\mu^\nu a_\nu, \qquad (8)$$

where Λ is a LORENTZ TENSOR.

To turn a CONTRAVARIANT TENSOR a^ν into a covariant tensor a_μ (INDEX LOWERING), use the METRIC TENSOR $g_{\mu\nu}$ to write

$$g_{\mu\nu} a^\nu = a_\mu. \qquad (9)$$

Covariant and contravariant indices can be used simultaneously in a MIXED TENSOR.

See also CONTRAVARIANT TENSOR, FOUR-VECTOR, INDEX LOWERING, LORENTZ TENSOR, METRIC TENSOR, MIXED TENSOR, TENSOR

Covariant Vector

A COVARIANT TENSOR of RANK 1, more commonly called a ONE-FORM (or "BRA").

See also BRA, CONTRAVARIANT VECTOR, CONTRAVARIANT TENSOR, KET, ONE-FORM, VECTOR

Cover

A family γ of nonempty SUBSETS of X whose UNION contains the given set X (and which contains no duplicated subsets) is called a cover (or covering) of X. For example, there is only a single cover of $\{1\}$, namely $\{1\}$ itself. However, there are five covers of $\{1, 2\}$, namely $\{\{1\},\{2\}\}$, $\{\{1, 2\}\}$, $\{\{1\},\{1, 2\}\}$, $\{\{2\},\{1, 2\}\}$, and $\{\{1\},\{2\},\{1, 2\}\}$.

A MINIMAL COVER is a cover for which removal of one member destroys the covering property. For example, of the five covers of $\{1, 2\}$, only $\{\{1\},\{2\}\}$ and $\{\{1, 2\}\}$ are minimal covers. There are various other types of specialized covers, including PROPER COVERS, antichain covers, k-covers, and k*-covers (Macula 1994).

The number of possible covers for a set of N elements are

$$|C(N)| = \frac{1}{2}\sum_{k=0}^{N}(-1)^k \binom{N}{k} 2^{2^{N-k}},$$

the first few of which are 1, 5, 109, 32297, 2147321017, 9223372023970362989, ... (Sloane's A003465).

Cover Relation

The transitive reflexive reduction of a PARTIAL ORDER. An element z of a POSET $(X, \leq)$ covers another element x provided that there exists no third element y in the poset for which $x \leq y \leq z$. In this case, z is called an "upper cover" of x and x a "lower cover" of z.

See also PARTIAL ORDER

Covering

COVER, COVERING MAP, PACKING

Covering Dimension

LEBESGUE COVERING DIMENSION

Covering Map

A covering map is a SURJECTIVE OPEN MAP $f: X \to Y$ whose preimages $f^{-1}(y)$ are a DISCRETE SET in X. For example, the map $f(z) = z^2$, as a map $f: \mathbb{C} - 0 \to \mathbb{C} -$

0, is a covering. Note that $f^{-1}(w)$ always consists of two points. In general, the cardinality of $f^{-1}(y)$ is independent of $y \in Y$.

Another example is $\pi : \mathbb{C} \to \mathbb{C}/\Gamma \simeq \mathbb{T}$, where $\Gamma = \{(a + bI) | a, b \in \mathbb{Z}\}$. The map π is actually the UNIVERSAL COVER of the torus $\mathbb{T}$. If $f : X \to \mathbb{T}$ is any covering of the torus, then there exists a covering $\tilde{\pi} : \mathbb{C} \to X$ such that π factors through $\tilde{\pi}$, i.e., $\pi = f \circ \tilde{\pi}$.

Cox's Theorem

Let σ_1, ..., σ_4 be four PLANES in GENERAL POSITION through a point P and let P_{ij} be a point on the LINE $\sigma_i \cdot \sigma_j$. Let σ_{ijk} denote the PLANE $P_{ij}P_{ik}P_{jk}$. Then the four PLANES σ_{234}, σ_{134}, σ_{124}, σ_{123} all pass through one point P_{1234}. Similarly, let σ_1, ..., σ_5 be five PLANES in GENERAL POSITION through P. Then the five points P_{2345}, P_{1345}, P_{1245}, P_{1235}, and P_{1234} all lie in one PLANE. And so on.

See also CLIFFORD'S CIRCLE THEOREM, PLANE

Cramér Conjecture

The unproven CONJECTURE that

$$\overline{\lim_{n\to\infty}} \frac{p_{n+1} - p_n}{(\ln p_n)^2} = 1,$$

where p_n is the nth PRIME.

Cramér-Euler Paradox

A curve of order n is generally determined by $n(n+3)/2$ points. So a CONIC SECTION is determined by five points and a CUBIC CURVE should require nine. But the MACLAURIN-BÉZOUT THEOREM says that two curves of degree n intersect in n^2 points, so two CUBICS intersect in nine points. This means that $n(n+3)/2$ points do not always uniquely determine a single curve of order n. The paradox was publicized by Stirling, and explained by Plücker.

See also CUBIC CURVE, MACLAURIN-BÉZOUT THEOREM

Cramer's Rule

Given a set of linear equations

$$\begin{cases} a_1x + b_1y + c_1z = d_1 \\ a_2x + b_2y + c_2z = d_2 \\ a_3x + b_3y + c_3z = d_3, \end{cases} \tag{1}$$

consider the DETERMINANT

$$D \equiv \begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}. \tag{2}$$

Now multiply D by x, and use the property of DETERMINANTS that MULTIPLICATION by a constant is equivalent to MULTIPLICATION of each entry in a given row by that constant

$$x\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} a_1x & b_1 & c_1 \\ a_2x & b_2 & c_2 \\ a_3x & b_3 & c_3 \end{vmatrix}. \tag{3}$$

Another property of DETERMINANTS enables us to add

a constant times any column to any column and obtain the same DETERMINANT, so add y times column 2 and z times column 3 to column 1,

$$xD = \begin{vmatrix} a_1x+b_1y+c_1z & b_1 & c_1 \\ a_2x+b_2y+c_2z & b_2 & c_2 \\ a_3x+b_3x+c_3z & b_3 & c_3 \end{vmatrix} = \begin{vmatrix} d_1 & b_1 & c_1 \\ d_2 & b_2 & c_2 \\ d_3 & b_3 & c_3 \end{vmatrix}. \quad (4)$$

If $\mathbf{d}=\mathbf{0}$, then (4) reduces to $xD=0$, so the system has nondegenerate solutions (i.e., solutions other than (0, 0, 0)) only if $D=0$ (in which case there is a family of solutions). If $\mathbf{d}\neq\mathbf{0}$ and $D=0$, the system has no unique solution. If instead $\mathbf{d}\neq\mathbf{0}$ and $D\neq 0$, then solutions are given by

$$x = \frac{\begin{vmatrix} d_1 & b_1 & c_1 \\ d_2 & b_2 & c_2 \\ d_3 & b_3 & c_3 \end{vmatrix}}{D}, \quad (5)$$

and similarly for

$$y = \frac{\begin{vmatrix} a_1 & d_1 & c_1 \\ a_2 & d_2 & c_2 \\ a_3 & d_3 & c_3 \end{vmatrix}}{D} \quad (6)$$

$$z = \frac{\begin{vmatrix} a_1 & b_1 & d_1 \\ a_2 & b_2 & d_2 \\ a_3 & b_3 & d_3 \end{vmatrix}}{D} \quad (7)$$

This procedure can be generalized to a set of n equations so, given a system of n linear equations

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} = \begin{bmatrix} d_1 \\ \vdots \\ d_n \end{bmatrix}, \quad (8)$$

let

$$D \equiv \begin{vmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{1n1} & a_{n2} & \cdots & a_{nn} \end{vmatrix}. \quad (9)$$

If $\mathbf{d}=\mathbf{0}$, then nondegenerate solutions exist only if $D=0$. If $\mathbf{d}\neq\mathbf{0}$ and $D=0$, the system has no unique solution. Otherwise, compute

$$D_k \equiv \begin{vmatrix} a_{11} & \cdots & a_{1(k-1)} & d_1 & a_{1(k+1)} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{n(k-1)} & d_n & a_{n(k+1)} & \cdots & a_{nn} \end{vmatrix}. \quad (10)$$

Then $x_k = D_k/D$ for $1\leq k\leq n$. In the 3-D case, the VECTOR analog of Cramer's rule is

$$(\mathbf{A}\times\mathbf{B})\times(\mathbf{C}\times\mathbf{D}) = (\mathbf{A}\cdot\mathbf{B}\times\mathbf{D})\mathbf{C} - (\mathbf{A}\cdot\mathbf{B}\times\mathbf{C})\mathbf{D}. \quad (11)$$

Cramér's Theorem

If X and Y are INDEPENDENT variates and $X+Y$ is a GAUSSIAN DISTRIBUTION, then both X and Y must have GAUSSIAN DISTRIBUTIONS. This was proved by Cramér in 1936.

Craps

A game played with two DICE. If the total is 7 or 11 (a "natural"), the thrower wins and retains the DICE for another throw. If the total is 2, 3, or 12 ("craps"), the thrower loses but retains the DICE. If the total is any other number (called the thrower's "point"), the thrower must continue throwing and roll the "point" value again before throwing a 7. If he succeeds, he wins and retains the DICE, but if a 7 appears first, the player loses and passes the DICE.

The following table summarizes the probabilities of winning on a roll-by-roll basis, where $P(p=n)$ is the probability of rolling a point n. For rolls that are not naturals (W) or craps (L), the probability that the point $p = n$ will be rolled first is found from

$$P(\text{win}|p=n) = \frac{P(p=n)}{P(p=7)+P(p=n)} = \frac{P(p=n)}{\frac{1}{6}36 + P(p=n)}.$$

n	$P(p=n)$	W/L	$P(\text{win}\mid p=n)$
2	$\frac{1}{36}$	L	0
3	$\frac{2}{36}$	L	0
4	$\frac{3}{36}$		$\frac{3}{9}$
5	$\frac{4}{36}$		$\frac{4}{10}$
6	$\frac{5}{36}$		$\frac{5}{11}$
7	$\frac{6}{36}$	W	1
8	$\frac{5}{36}$		$\frac{5}{11}$
9	$\frac{4}{36}$		$\frac{4}{10}$
10	$\frac{3}{36}$		$\frac{3}{9}$
11	$\frac{2}{36}$	W	1
12	$\frac{1}{36}$	L	0

Summing $P(p=n)$ from $n=1$ to 12 then gives the probability of winning as $244/495\approx 0.492929$ (Kraitchik 1942), just under 50%.

Cribbage
Cribbage is a game in which each of two players is dealt a hand of six CARDS. Each player then discards two of his six cards to a four-card "crib" which alternates between players. After the discard, the top card in the remaining deck is turned up. Cards are then alternately played out by the two players, with points being scored for pairs, runs, cumulative total of 15 and 31, and playing the last possible card ("go") not giving a total over 31. All face cards are counted as 10 for the purpose of playing out, but the normal values of $\text{Jack} = 11$, $\text{Queen} = 12$, $\text{King} = 13$ are used to determine runs. Aces are always low $(\text{ace} = 1)$. After all cards have been played, each player counts the four cards in his hand taken in conjunction with the single top card. Points are awarded for pairs, flushes, runs, and combinations of cards giving 15. A Jack having the same suit as a top card is awarded an additional point for "nobbs." The crib is then also counted and scored. The winner is the first person to "peg" a certain score, as recorded on a "cribbage board."

The best possible score in a hand is 29, corresponding to three 5s and a Jack with a top 5 the same suit as the Jack. Hands with scores of 19, 25, 26, and 27 are not possible. A hand scoring zero points is therefore sometimes humorously referred to as a "19-point" hand.

Criss-Cross Method
A standard form of the LINEAR PROGRAMMING problem of maximizing a linear function over a CONVEX POLYHEDRON is to maximize $\mathbf{c} \cdot \mathbf{x}$ subject to $\mathbf{mx} \le \mathbf{b}$ and $\mathbf{x} \ge \mathbf{0}$, where m is a given $s \times d$ matrix, $\mathbf{c}$ and $\mathbf{b}$ are given d-vector and s-vectors, respectively. The Criss-cross method always finds a VERTEX solution if an optimal solution exists.

Critical Damping
DAMPED SIMPLE HARMONIC MOTION–CRITICAL DAMPING

Critical Index
Let F be the MACLAURIN SERIES of a MEROMORPHIC FUNCTION f with a finite or infinite number of POLES at points z_k, indexed so that

$$0 < |z_1| \le |z_2| \le |z_3| \le \ldots,$$

then a POLE will occur as many times in the sequence $\{z_k\}$ as indicated by its order. Any index such that

$$|z_m| < |z_{m+1}|$$

holds is then called a critical index of f (Henrici 1988, pp. 641–42).

Crofton's Integrals

Consider a convex plane curve K with PERIMETER L, and the set of points P exterior to K. Further, let t_1 and t_2 be the perpendicular distances from P to K (with corresponding tangent points A_1 and A_2 on K), and let $\omega = \angle A_1PA_2$. Then

$$\int_{P \text{ ext. to } K} \frac{\sin\omega}{t_1t_2}\, dP = 2\pi^2 \qquad (1)$$

(Crofton 1885; Solomon 1978, p. 28).

If K has a continuous RADIUS OF CURVATURE and the radii of curvature at points A_1 and A_2 are ρ_1 and ρ_2, then

$$\int_{P \text{ ext. to } K} \frac{\sin\omega}{t_1t_2}\, \rho_1\rho_2\, dP = \tfrac{1}{2}L^2 \qquad (2)$$

(Solomon 1978, p. 28), and furthermore

$$\int_{P \text{ ext. to } K} \frac{\sin\omega}{t_1t_2}(\rho_1+\rho_2)\, dP = 2\pi L \qquad (3)$$

(Santaló 1953; Solomon 1978, p. 28).

Crookedness

Let a KNOT K be parameterized by a VECTOR FUNCTION $\mathbf{v}(t)$ with $t \in \mathbb{S}^1$, and let $\mathbf{w}$ be a fixed UNIT VECTOR in $\mathbb{R}^3$. Count the number of RELATIVE MINIMA of the projection function $\mathbf{w} \cdot \mathbf{v}(t)$. Then the MINIMUM such number over all directions $\mathbf{w}$ and all K of the given type is called the crookedness $\mu(K)$. Milnor (1950) showed that $2\pi\mu(K)$ is the INFIMUM of the total curvature of K. For any TAME KNOT K in $\mathbb{R}^3$, $\mu(K) = b(K)$ where $b(K)$ is the BRIDGE INDEX.

See also BRIDGE INDEX

Cross

In general, a cross is a figure formed by two intersecting LINE SEGMENTS. In LINEAR ALGEBRA, a cross is defined as a set of n mutually PERPENDICULAR pairs of VECTORS of equal magnitude from a fixed origin in EUCLIDEAN n-SPACE.

The word "cross" is also used to denote the operation of the CROSS PRODUCT, so $\mathbf{a} \times \mathbf{b}$ would be pronounced "**a** cross **b**."

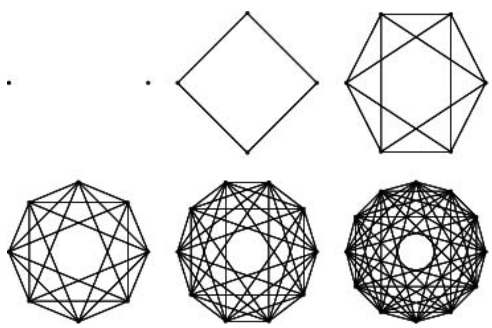
GAULLIST CROSS

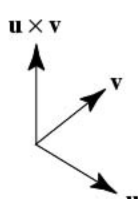
Cross Polytope



A regular POLYTOPE in n-D corresponding to the CONVEX HULL of the points formed by permuting the coordinates ($\pm$ 1, 0, 0, ..., 0). A cross-polytope (also called an orthoplex) is denoted ? missing and has $2n$ vertices and SCHLÄFLI SYMBOL

$$\{\underbrace{3, \ldots, 3}_{n-2}, 4\}.$$

The cross polytope is named because its $2n$ vertices are located equidistant from the origin along the Cartesian axes in n-space, which each such axis perpendicular to all others. A cross polytope is bounded by 2^n $(n-1)$-simplexes, and is a dipyramid erected (in both directions) into the nth dimension, with an $(n-1)$-dimensional cross polytope as its base.



In 1-D, the cross polytope is the LINE SEGMENT [−1, 1]. In 2-D, the cross polytope {4} is the filled SQUARE with vertices (−1, 0), (0, −1), (1, 0), (0, 1). In 3-D, the cross polytope (3, 4) is the convex hull of the OCTAHEDRON with vertices (−1, 0, 0), (0, −1, 0), (0, 0, −1), (1, 0, 0), (0, 1, 0), (0, 0, 1). In 4-D, the cross polytope {3, 3, 4} is the 16-CELL, depicted in the above figure by projecting onto one of the four mutually perpendicular 3-spaces within the 4-space obtained by dropping one of the four vertex components (R. Towle).

The graph of β_n missing is isomorphic with the CIRCULANT GRAPH $Ci_{1,\ 2,\ldots,(n-1)}(2n)$.

See also 16-CELL, HYPERCUBE, POLYTOPE, SIMPLEX

Cross Product

For VECTORS **u** and **v**, the cross product is defined by

$$\mathbf{u}\times\mathbf{v}=\hat{\mathbf{x}}(u_y v_z - u_z v_y)-\hat{\mathbf{y}}(u_x v_z - u_z v_x) + \hat{\mathbf{z}}(u_x v_y - u_y v_x). \qquad (1)$$

This can be written in a shorthand NOTATION which takes the form of a DETERMINANT

$$\mathbf{u}\times\mathbf{v}=\begin{vmatrix}\hat{\mathbf{x}} & \hat{\mathbf{y}} & \hat{\mathbf{z}}\\ u_x & u_y & u_z\\ v_x & v_y & v_z\end{vmatrix}. \qquad (2)$$

Here, $\mathbf{u}\times\mathbf{v}$ is always PERPENDICULAR to both **u** and **v**, with the orientation determinant by the RIGHT-HAND RULE. It is also true that

$$|\mathbf{u}\times\mathbf{v}|=|\mathbf{u}||\mathbf{v}|\sin\theta, \qquad (3)$$

$$=|\mathbf{u}||\mathbf{v}|\sqrt{1-(\hat{\mathbf{u}}\cdot\hat{\mathbf{v}})^2}, \qquad (4)$$

where θ is the angle between **u** and **v**, given by the DOT PRODUCT

$$\cos\theta\equiv\hat{\mathbf{u}}\cdot\hat{\mathbf{v}}. \qquad (5)$$

Jeffreys and Jeffreys (1988) use the notation $\mathbf{u}\wedge\mathbf{v}$ to denote the cross product.
The cross product is implemented in *Mathematica* 3.0 and higher as Cross[*a*, *b*].
Identities involving the cross product include

$$\frac{d}{dt}[\mathbf{r}_1(t)\times\mathbf{r}_2(t)]=\mathbf{r}_1(t)\times\frac{d\mathbf{r}_2}{dt}+\frac{d\mathbf{r}_1}{dt}\times\mathbf{r}_2(t) \qquad (6)$$

$$\mathbf{A}\times\mathbf{B}=-\mathbf{B}\times\mathbf{A} \qquad (7)$$

$$\mathbf{A}\times(\mathbf{B}+\mathbf{C})=\mathbf{A}\times\mathbf{B}+\mathbf{A}\times\mathbf{C} \qquad (8)$$

$$(t\mathbf{A})\times\mathbf{B}=t(\mathbf{A}\times\mathbf{B}). \qquad (9)$$

For a proof that $\mathbf{A}\times\mathbf{B}$ is a PSEUDOVECTOR, see Arfken (1985, pp. 22–3). In TENSOR notation,

$$\mathbf{A}\times\mathbf{B}=\epsilon_{ijk}A^jB^k, \qquad (10)$$

where ϵ_{ijk} is the PERMUTATION SYMBOL.

Cross Section

The cross section of a SOLID is a plane figure obtained by its intersection with a PLANE. The cross section of an object therefore represents an infinitesimal "slice" of a solid, and may be different depending on the orientation of the slicing plane. While the cross section of a SPHERE is always a DISK, the cross section of a CUBE may be a SQUARE, HEXAGON, or other shape.

See also AXONOMETRY, CAVALIERI'S PRINCIPLE, INNER QUERMASS, LAMINA, PLANE, PROJECTION, RADON TRANSFORM, STEREOLOGY

Cross Sequence

A sequence

$$s_n^{(\lambda)}(x)=[h(t)]^\lambda s_n(x),$$

where $s_n(x)$ is a SHEFFER SEQUENCE, $h(t)$ is invertible, and λ ranges over the real numbers is called a STEFFENSEN SEQUENCE. If $s_n(x)$ is an associated SHEFFER SEQUENCE, then $s_n^{(\lambda)}$ is called a cross sequence.

Examples include the ACTUARIAL POLYNOMIAL and POISSON-CHARLIER POLYNOMIAL.

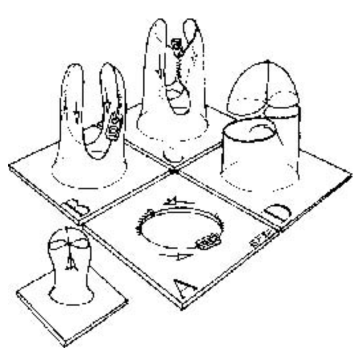
Cross Surface

A SPHERE with a single CROSS-CAP. This term is more appropriate in purely topological applications than the more common term REAL PROJECTIVE PLANE, which implies the presence of an affine structure (Francis and Weeks 1999). The double cross surface is the KLEIN BOTTLE and the triple cross surface is called DYCK'S SURFACE (Francis and Collins 1993, Francis and Weeks 1999).



See also CROSS-CAP, REAL PROJECTIVE PLANE

References

Francis, G. and Collins, B. "On Knot-Spanning Surfaces: An Illustrated Essay on Topological Art." Ch. 11 in *The Visual Mind: Art and Mathematics* (Ed. M. Emmer). Cambridge, MA: MIT Press, 1993.

Cross-Cap

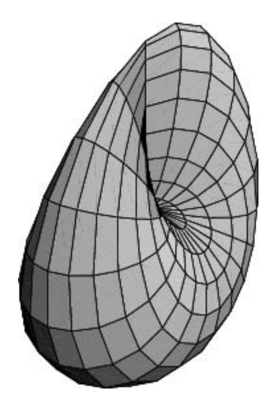
The self-intersection of a one-sided SURFACE. "Cross-cap" is sometimes also written without the hyphen as the single word "crosscap." The cross-cap can be thought of as the object produced by puncturing a surface a single time, attaching two ZIPS around the puncture in the same direction, distorting the hole so that the zips line up, requiring that the surface intersect itself, and then zipping up. The cross-cap can also be described as a circular HOLE which, when entered, exits from its opposite point (from a topological viewpoint, both singular points on the cross-cap are equivalent).

The cross-cap has a segment of double points which terminates at two "PINCH POINTS" known as WHITNEY SINGULARITIES. A CROSS-HANDLE is homeomorphic to two cross-caps (Francis and Weeks 1999).

A SPHERE with one cross-cap has traditionally been called a REAL PROJECTIVE PLANE. While this is appropriate in the study of PROJECTIVE GEOMETRY when an affine structure is present, J. H. Conway advocates use of the term CROSS SURFACE in a purely topological interpretation (Francis and Weeks 1999). The cross-cap is one of the three possible SURFACES obtained by sewing a MÖBIUS STRIP to the edge of a DISK. The other two are the BOY SURFACE and ROMAN SURFACE.

The cross-cap can be generated using the general method for NONORIENTABLE SURFACES using the polynomial function

$$\mathbf{f}(x,\ y,\ z)=(xz,\ yz,\ \tfrac{1}{2}(z^2-x^2)) \tag{1}$$



(Pinkall 1986). Transforming to SPHERICAL COORDINATES gives

$$x(u,\ v)=\tfrac{1}{2}\cos u\ \sin(2v) \tag{2}$$

$$y(u,\ v)=\tfrac{1}{2}\sin u\ \sin(2v) \tag{3}$$

$$z(u,\ v)=\tfrac{1}{2}(\cos^2 v-\cos^2 u\ \sin^2 v) \tag{4}$$

for $u\in[0,\ 2\pi)$ and $v\in[0,\ \pi/2]$. To make the equations slightly simpler, all three equations are normally multiplied by a factor of 2 to clear the arbitrary scaling constant. Three views of the cross-cap generated using this equation are shown above. Note that the middle one looks suspiciously like BOUR'S MINIMAL SURFACE.

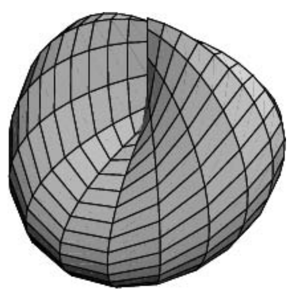
Another representation is

$$\mathbf{f}(x,\ y,\ z)=(yz,\ 2xy,\ x^2-y^2), \tag{5}$$

(Gray 1997), giving PARAMETRIC EQUATIONS

$$x = \frac{1}{2}\sin u \sin(2v) \quad (6)$$

$$y = \sin(2u)\sin^2 v \quad (7)$$



$$z = \cos(2u)\sin^2 v, \quad (8)$$

(Geometry Center) where, for aesthetic reasons, the y- and z-coordinates have been multiplied by 2 to produce a squashed, but topologically equivalent, surface. Nordstrand gives the implicit equation

$$4x^2(x^2+y^2+z^2+z)+y^2(y^2+z^2-1)=0 \quad (9)$$

which can be solved for z to yield

$$z = \frac{-2x^2 \pm \sqrt{(y^2+2x^2)(1-4x^2-y^2)}}{4x^2+y^2}. \quad (10)$$

Taking the inversion of a cross-cap such that (0, 0, –1/2) is sent to ∞ gives a CYLINDROID, shown above (Pinkall 1986).

Cross-Correlation

The cross-correlation of two COMPLEX FUNCTIONS $f(t)$ and $g(t)$ of a real variable t, denoted $f \star g$ is defined by

$$f \star g \equiv \bar{f}(-t) * g(t), \quad (1)$$

where $*$ denotes CONVOLUTION and $\bar{f}(t)$ is the COMPLEX CONJUGATE of $f(t)$. Since CONVOLUTION is defined by

$$f(t) * g(t) = \int_{-\infty}^{\infty} f(\tau)g(t-\tau)\,d\tau, \quad (2)$$

it follows that

$$f \star g \equiv \int_{-\infty}^{\infty} \bar{f}(-\tau)g(t-\tau)\,d\tau. \quad (3)$$

Letting $\tau' = -\tau$, $d\tau' = -d\tau$ so (3) is equivalent to

$$f \star g = \int_{\infty}^{-\infty} \bar{f}(\tau')g(t+\tau')(-d\tau')$$

$$= \int_{-\infty}^{\infty} \bar{f}(\tau)g(t+\tau)\,d\tau. \quad (4)$$

The cross-correlation satisfies the identity

$$(g \star h) \star (g \star h) = (g \star g) \star (h \star h). \quad (5)$$

If f or g is EVEN, then

$$f \star g = f * g, \quad (6)$$

where $*$ again denotes CONVOLUTION.

Cross-Correlation Coefficient

The COEFFICIENT ρ in a GAUSSIAN BIVARIATE DISTRIBUTION.

Cross-Correlation Theorem

Let $f \star g$ denote the CROSS-CORRELATION of functions $f(t)$ and $g(t)$. Then

$$\begin{aligned}f \star g &= \int_{-\infty}^{\infty} \bar{f}(\tau) g(t+\tau)\, d\tau \\ &= \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} \bar{F}(\nu) e^{2\pi i \nu \tau}\, d\nu \int_{-\infty}^{\infty} G(\nu') e^{-2\pi i \nu' (t+\tau)}\, d\nu' \right] d\tau \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \bar{F}(\nu) G(\nu') e^{-2\pi i \tau (\nu' - \nu)}\, e^{-2\pi i \nu' t}\, d\tau\, d\nu\, d\nu' \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \bar{F}(\nu) G(\nu') e^{-2\pi i \nu' t} \left[\int_{-\infty}^{\infty} e^{-2\pi i \tau (\nu' - \nu)}\, d\tau \right] d\nu\, d\nu' \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \bar{F}(\nu) G(\nu') e^{-2\pi i \nu' t} \delta(\nu' - \nu)\, d\nu'\, d\nu \\ &= \int_{-\infty}^{\infty} \bar{F}(\nu) G(\nu) e^{-2\pi i \nu t}\, d\nu \end{aligned} \quad (1)$$

where $\mathcal{F}$ denotes the FOURIER TRANSFORM, $\bar{z}$ is the COMPLEX CONJUGATE, and

$$f(t) \equiv \mathcal{F}[F(\nu)] = \int_{-\infty}^{\infty} F(\nu) e^{-2\pi i \nu t}\, dt \quad (2)$$

$$g(t) \equiv \mathcal{F}[G(\nu)] = \int_{-\infty}^{\infty} G(\nu) e^{-2\pi i \nu t}\, dt. \quad (3)$$

Applying a FOURIER TRANSFORM on each side gives the cross-correlation theorem,

$$f \star g = \mathcal{F}[\bar{F}(\nu) G(\nu)]. \quad (4)$$

If $F = G$, then the cross-correlation theorem reduces to the WIENER-KHINTCHINE THEOREM.

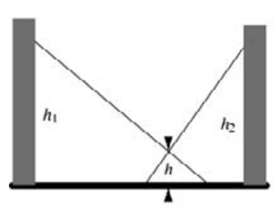
Crossed Ladders Problem

Given two crossed LADDERS resting against two buildings, what is the distance between the buildings? Let the height at which they cross be h and the lengths of the LADDERS l_1 and l_2. The height at which l_2 touches the building h_2 is then obtained by simultaneously solving the equations

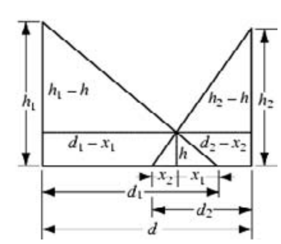
$$l_1^2 = h_1^2 + d^2 \quad (1)$$

$$l_2^2 = h_2^2 + d^2 \quad (2)$$

and



$$\frac{1}{h} = \frac{1}{h_1} + \frac{1}{h_2}, \quad (3)$$

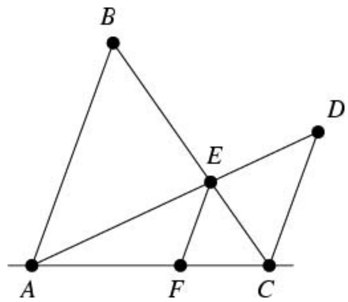


the latter of which follows either immediately from the CROSSED LADDERS THEOREM or from similar triangles with $d_1 = dh/h_2$, $d_2 = dh/h_1$, and $d = d_1 + d_2$. Eliminating d gives the equations

$$h_1^4 - 2hh_1^3 + (h - h_1)^2 (l_2^2 - l_1^2) = 0. \quad (4)$$

$$h_2^4 - 2hh_2^3 + (h - h_2)^2 (l_1^2 - l_2^2) = 0. \quad (5)$$

These quartic equations can be solved for h_1 and h_2 given known values of h, l_1, and l_2.
There are solutions in which not only l_1, l_2, h_1, h_2, and h are all integers, but so are d_1, and d_2. One example is $h_1 = 119$, $h_1 = 70$, $h = 30$, $d_1 = 40$, $d_2 = 16$.



The problem can also be generalized to the situation in which the ends of the ladders are not pinned against the buildings, but propped fixed distances d_1 and d_2 away.

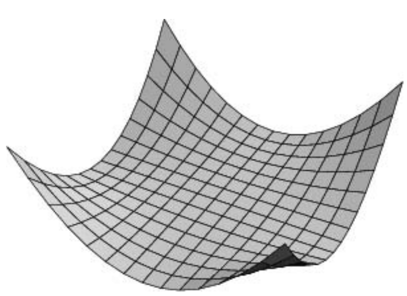
Crossed Ladders Theorem

In the above figure, let E be the intersection of AD and BC and specify that $AB \parallel EF \parallel CD$. Then

$$\frac{1}{AB}+\frac{1}{CD}=\frac{1}{EF}.$$



A beautiful related theorem due to H. Stengel can be stated as follows. In the above figure, let E lie on the side AB and D lie on the side BC. Now let EC intersect the line AD at a point F, and construct points H, I, and J so that $EI \parallel DH \parallel FJ \parallel BG$. Then

$$\frac{1}{EI}+\frac{1}{DH}=\frac{1}{FJ}+\frac{1}{BG}.$$

Cross-Handle

A cross-handle is a topological structure which can be thought of as the object produced by puncturing a surface twice, attaching a ZIP around each puncture travelling in the same direction, pulling the edges of the zips together after one tube first passes through itself it order for the direction of the zips to match up, and then zipping up. In 3-space, the cross-handle contains a line of self-intersection.

A cross-handle is homeomorphic to two CROSS-CAPS (Francis and Weeks 1999). DYCK'S THEOREM states that HANDLES and cross-handles are equivalent in the presence of a CROSS-CAP.

See also CAP, CROSS-CAP, DYCK'S THEOREM, HANDLE

Crossing Number (Graph)

Given a "good" GRAPH G (i.e., one for which all intersecting EDGES intersect in a single point and arise from four distinct VERTICES), the crossing number $\nu(G)$ is the minimum possible number of crossings with which the GRAPH can be drawn. A GRAPH with crossing number 0 is a PLANAR GRAPH. Garey and Johnson (1983) showed that determining the crossing number is an NP-COMPLETE PROBLEM.

GUY'S CONJECTURE suggests that the crossing number for the COMPLETE GRAPH K_n is

$$\nu(K_n)=\frac{1}{4}\left\lfloor\frac{n}{2}\right\rfloor\left\lfloor\frac{n-1}{2}\right\rfloor\left\lfloor\frac{n-2}{2}\right\rfloor\left\lfloor\frac{n-3}{2}\right\rfloor, \quad (1)$$

which can be rewritten

$$\nu(K_n) = \begin{cases} \frac{1}{64} n(n-2)^2(n-4) & \text{for } n \text{ even} \\ \frac{1}{64}(n-1)^2(n-3)^2 & \text{for } n \text{ odd.} \end{cases} \tag{2}$$

The values of (2) for $n = 1, 2, \ldots$ are then given by 0, 0, 0, 0, 1, 3, 9, 18, 36, 60, 100, 150, 225, 315, 441, 588, ... (Sloane's A000241), although it has not been proven that these agree with the actual crossing numbers for $n \geq 11$.

ZARANKIEWICZ'S CONJECTURE asserts that the crossing number for a COMPLETE BIGRAPH is

$$\nu(K_{m,\,n}) = \left\lfloor \frac{n}{2} \right\rfloor \left\lfloor \frac{n-1}{2} \right\rfloor \left\lfloor \frac{m}{2} \right\rfloor \left\lfloor \frac{m-1}{2} \right\rfloor. \tag{3}$$

It has been checked up to $m,\ n = 7$, and Zarankiewicz has shown that, in general, the FORMULA provides an upper bound to the actual number. The table below gives known results. When the number is not known exactly, the prediction of ZARANKIEWICZ'S CONJECTURE is given in parentheses.

	1	2	3	4	5	6	7
1	0	0	0	0	0	0	0
2		0	0	0	0	0	0
3			1	2	4	6	9
4				4	8	12	18
5					16	24	36
6						36	54
7							77, 79, or (81)

Kleitman (1970, 1976) computed the exact crossing numbers $\nu(K_{5,\,n})$ for all positive n.

Cross-Ratio

$$[a,\ b,\ c,\ d] \equiv \frac{(a-b)(c-d)}{(a-d)(c-b)}. \tag{1}$$

For a MÖBIUS TRANSFORMATION f,

$$[a,\ b,\ c,\ d] = [f(a),\ f(b),\ f(c),\ f(d)]. \tag{2}$$

There are six different values which the cross-ratio may take, depending on the order in which the points

are chosen. Let $\lambda \equiv [a, b, c, d]$. Possible values of the cross-ratio are then λ, $1-\lambda$, $1/\lambda$, $(\lambda-1)/\lambda$, $1/(1-\lambda)$, and $\lambda/(\lambda-1)$.

Given lines a, b, c, and d which intersect in a point O, let the lines be cut by a line l, and denote the points of intersection of l with each line by A, B, C, and D. Let the distance between points A and B be denoted AB, etc. Then the cross-ratio

$$[AB, CD] \equiv \frac{(AB)(CD)}{(BC)(AD)} \tag{3}$$

is the same for any position of the l (Coxeter and Greitzer 1967). Note that the definitions $(AB/AD)/(BC/CD)$ and $(CA/CB)/(DA/DB)$ are used instead by Kline (1990) and Courant and Robbins (1966), respectively. The identity

$$[AD, BC] + [AB, DC] = 1 \tag{4}$$

holds IFF $AC//BD$, where // denotes SEPARATION.

The cross-ratio of four points on a radial line of an INVERSION CIRCLE is preserved under INVERSION (Ogilvy 1990, p. 40).

Cruciform

A plane curve also called the CROSS CURVE and POLICEMAN ON POINT DUTY CURVE (Cundy and Rollett 1989). It is given by the equation

$$x^2y^2 - a^2x^2 - b^2y^2 = 0, \tag{1}$$

which is equivalent to

$$1 - \frac{a^2}{x^2} - \frac{b^2}{y^2} = 0 \tag{2}$$

$$\frac{a^2}{x^2} + \frac{b^2}{y^2} = 1, \tag{3}$$

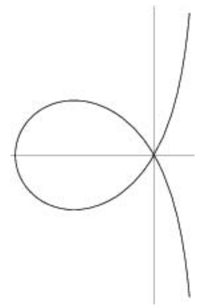
or, rewriting,

$$y^2 = \frac{b^2x^2}{x^2 - a^2}. \tag{4}$$

In parametric form,

$$x = a \sec t \tag{5}$$

$$y = b \csc t. \tag{6}$$



The CURVATURE is

$$\kappa = \frac{3ab \csc^2 t \sec^2 t}{(b^2 \cos^2 t \cos^2 t a^2 \sec^2 t \tan^2 t)^{3/2}}. \tag{7}$$

Crystallographic Point Groups

The crystallographic point groups are the point groups in which translational periodicity is required (the so-called crystallography restriction). There are 32 such groups, summarized in the following table which organized them by Schönflies symbol type.

type	point groups
nonaxial	C_i, C_s
cyclic	C_1, C_2, C_3, C_4, C_6
cyclic with horizontal planes	C_{2h}, C_{3h}, C_{4h}, C_{6h}
cyclic with vertical planes	C_{2v}, C_{3v}, C_{4v}, C_{6v}
dihedral	D_2, D_3, D_4, D_6
dihedral with horizontal planes	D_{2h}, D_{3h}, D_{4h}, D_{6h}
dihedral with planes between axes	D_{2d}, D_{3d}
improper rotation	S_4, S_6
cubic groups	T, T_h, T_d, O, O_h

Note that while the tetrahedral T_d and octahedral O_h point groups are also crystallographic point groups, the icosahedral group I_h is not. The orders, classes, and group operations for these groups can be concisely summarized in their character tables.

Crystallography Restriction

If a discrete group of displacements in the plane has more than one center of rotation, then the only rotations that can occur are by 2, 3, 4, and 6. This can be shown as follows. It must be true that the sum of the interior angles divided by the number of sides is a divisor of 360°.

$$\frac{180°(n-2)}{n}=\frac{360°}{m},$$

where m is an integer. Therefore, symmetry will be possible only for

$$\frac{2n}{n-2}=m,$$

where m is an integer. This will hold for 1-, 2-, 3-, 4-, and 6-fold symmetry. That it does not hold for $n>6$ is seen by noting that $n=6$ corresponds to $m=3$. The $m=2$ case requires that $n=n-2$ (impossible), and the $m=1$ case requires that $n=-2$ (also impossible).

The point groups that satisfy the crystallographic restriction are called crystallographic point groups.

Császár Polyhedron

A POLYHEDRON topologically equivalent to a TORUS which was discovered in the late 1940s by Ákos Császár (Gardner 1975). It has 7 VERTICES, 14 faces, and 21 EDGES, and is the DUAL POLYHEDRON of the SZILASSI POLYHEDRON.

The SKELETON of the Császár polyhedron, illustrated above, is ISOMORPHIC to the COMPLETE GRAPH K_7. Rather surprisingly, the graph of the Császár polyhedron's skeleton and its DUAL GRAPH can be used to find STEINER TRIPLE SYSTEMS (Gardner 1975).

The figure above shows how to construct the Császár polyhedron.

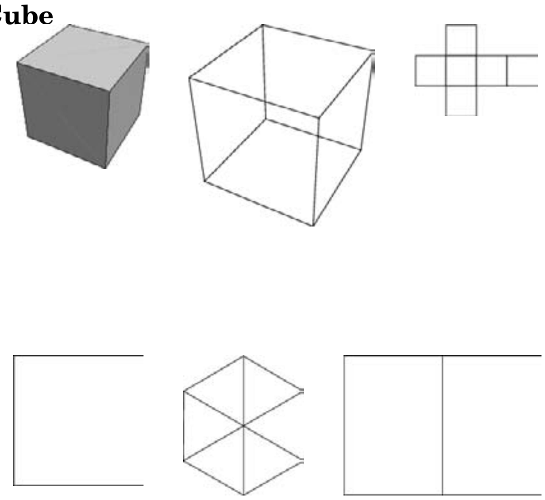
Cubature



Ueberhuber (1997, p. 71) and Krommer and Ueberhuber (1998, pp. 49 and 155–65) use the word "QUADRATURE" to mean numerical computation of a univariate INTEGRAL, and "cubature" to mean numerical computation of a MULTIPLE INTEGRAL. Cubature techniques available in *Mathematica* include MONTE CARLO INTEGRATION, implemented as `NIntegrate[`*f*, ..., `Method->MonteCarlo]` or `NIntegrate[`*f*, ..., `Method->QuasiMonteCarlo]`, and the adaptive Genz-Malik algorithm, implemented as `NIntegrate[`*f*, ..., `Method->MultiDimensional]`.

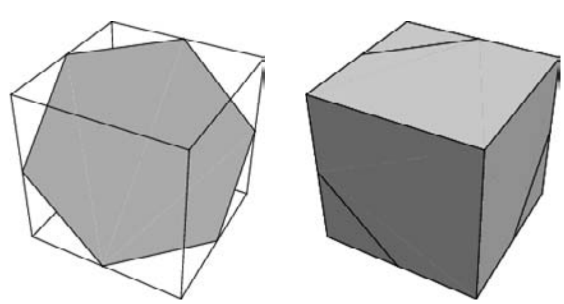
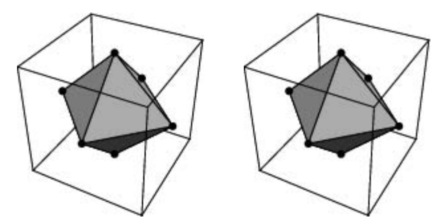
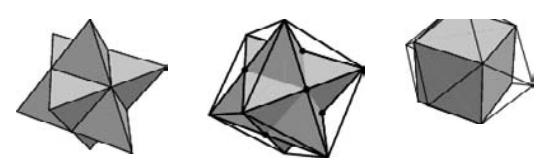
Cube



The three-dimensional PLATONIC SOLID P_3 which is also called the HEXAHEDRON. The cube is composed of six SQUARE faces, $6\{4\}$, which meet each other at RIGHT ANGLES, and has eight VERTICES and 12 EDGES. It is also the UNIFORM POLYHEDRON U_6 and Wenninger model W_3. It is described by the SCHLÄFLI SYMBOL $\{4, 3\}$ and WYTHOFF SYMBOL $3|24$.



The DUAL POLYHEDRON of the cube is the OCTAHEDRON. It has the O_h OCTAHEDRAL GROUP of symmetries, and is a ZONOHEDRON. The connectivity of the vertices is given by the CUBICAL GRAPH.



Because the VOLUME of a cube of side length n is given by n^3, a number OF THE FORM n^3 is called a CUBIC NUMBER (or sometimes simply "a cube"). Similarly, the operation of taking a number to the third POWER is called CUBING. Sodium chloride (NaCl; common table salt) naturally forms cubic crystals. Using so-called "wallet hinges," a ring of six cubes can be rotated continuously (Wells 1975; Wells 1991, pp. 218–19).

The cube cannot be STELLATED. A PLANE passing through the MIDPOINTS of opposite sides (perpendicular to a C_3 axis) cuts the cube in a regular HEXAGONAL CROSS SECTION (Gardner 1960; Steinhaus 1983, p. 170; Cundy and Rollett 1989, p. 157; Holden 1991, pp. 22–3). Since there are four such axes, there are four possible HEXAGONAL CROSS SECTIONS. If the vertices of the cube are $(\pm 1, \pm 1, \pm 1)$, then the vertices of the inscribed HEXAGON are $(0, -1, -1)$, $(1, 0, -1)$, $(1, 1, 0)$, $(0, 1, 1)$, $(-1, 0, 1)$, and $(-1, -1, 0)$. A HEXAGON is also obtained when the cube is viewed from above a corner along the extension of a space diagonal (Steinhaus 1983, p. 170). A HYPERBOLOID of one sheet is obtained as the envelope of a cube rotated about a space diagonal (Steinhaus 1983, pp. 171–72).

The centers of the faces of an OCTAHEDRON form a cube, and the centers of the faces of a cube form an OCTAHEDRON (Steinhaus 1983, pp. 194–95). The largest SQUARE which will fit inside a cube of side a has each corner a distance 1/4 from a corner of a cube. The resulting SQUARE has side length $3\sqrt{2}\,a/4$, and the cube containing that side is called PRINCE RUPERT'S CUBE.

The solid formed by the faces having the sides of the STELLA OCTANGULA (left figure) as DIAGONALS is a cube (right figure; Ball and Coxeter 1987). Affixing a SQUARE PYRAMID of height 1/2 on each face of a cube having unit edge length results in a RHOMBIC DODECAHEDRON (Brückner 1900, p. 130; Steinhaus 1983, p. 185).

The cube can be constructed by CUMULATION of a unit edge-length TETRAHEDRON by a pyramid with height $\frac{1}{6}\sqrt{6}$. The following table gives polyhedra which can be constructed by CUMULATION of a *cube* by pyramids of given heights h.

h	$(r+h)/h$	Result
$\frac{1}{6}$	$4/3$	TETRAKIS HEXAHEDRON
$\frac{1}{2}$	2	RHOMBIC DODECAHEDRON
$\frac{1}{2}\sqrt{2}$	$1+\sqrt{2}$	24-faced star DELTAHEDRON

The VERTICES of a cube of side length 2 with face-centered axes are given by $(\pm 1, \pm 1, \pm 1)$. If the cube is oriented with a space diagonal along the Z-AXIS, the coordinates are $(0, 0, \sqrt{3})$, $(0, 2\sqrt{2/3}, 1/\sqrt{3})$, $(\sqrt{2}, \sqrt{2/3}, -1/\sqrt{3})$, $(\sqrt{2}, -\sqrt{2/3}, 1/\sqrt{3})$, $(0, -2\sqrt{2/3}, -1/\sqrt{3})$, $(-\sqrt{2}, -\sqrt{2/3}, 1/\sqrt{3})$, $(-\sqrt{2}, \sqrt{2/3}, -1/\sqrt{3})$, and the negatives of these vectors. A FACETED version is the GREAT CUBICUBOCTAHEDRON.

A cube of side length 1 has INRADIUS, MIDRADIUS, and CIRCUMRADIUS of

$$r = \tfrac{1}{2} = 0.5 \tag{1}$$

$$\rho = \tfrac{1}{2}\sqrt{2} \approx 0.70710 \tag{2}$$

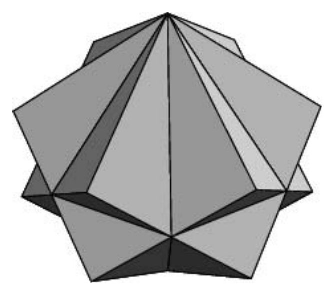
$$R = \tfrac{1}{2}\sqrt{3} \approx 0.86602. \tag{3}$$

The cube has a DIHEDRAL ANGLE of

$$\alpha = \tfrac{1}{2}\pi. \tag{4}$$

The SURFACE AREA and VOLUME of the cube are

$$S = 6a^2 \tag{5}$$



$$V = a^3. \tag{6}$$

Cube 3-Compound

A compound with the symmetry of the CUBE which arises by joining three CUBES such that each shares

two C_2 axes (Holden 1971, p. 35). The solid is depicted atop the left pedestle in M. C. Escher's woodcut *Waterfall*.

Weisstein, E. W. "Polyhedra." MATHEMATICA NOTEBOOK POLYHEDRA.M.

Cube 4-Compound

A compound also called BAKOS' COMPOUND having the symmetry of the CUBE which arises by joining four CUBES such that each C_3 axis falls along the C_3 axis of one of the other CUBES (Bakos 1959; Holden 1971, p. 35). Let the first cube c_1 consists of a cube in standard position rotated by $\pi/3$ radians around the (1, 1, 1)-axis, then the other three cubes are obtained by rotating c_1 around the (0, 0, 1)-axis (Z-AXIS) by $\pi/2$, $-\pi/2$, and π radians, respectively.

Cube 5-Compound

A POLYHEDRON COMPOUND consisting of the arrangement of five CUBES in the VERTICES of a DODECAHEDRON (or the centers of the faces of the ICOSAHEDRON). The cube 5-compound is the dual of the OCTAHEDRON 5-COMPOUND.

In the above figure, let $a = 1$ be the length of a CUBE EDGE. Then

$$x = \tfrac{1}{2}(3 - \sqrt{5})$$

$$\theta = \tan^{-1}\left(\frac{3 - \sqrt{5}}{2}\right) \approx 20°54'$$

$$\phi = \tan^{-1}\left(\frac{\sqrt{5} - 1}{2}\right) \approx 31°43'$$

$$\psi = 90° - \phi \approx 58°17'$$

$$\alpha = 90° - \theta \approx 69°06'.$$

The compound is most easily constructed using pieces like the ones in the above line diagram. The cube 5-compound has the 30 facial planes of the RHOMBIC TRIACONTAHEDRON (Steinhaus 1983, pp. 199 and 209; Ball and Coxeter 1987).

For cubes of unit edge lengths, the resulting compound has edge lengths

$$s_1 = \tfrac{1}{2}\sqrt{\tfrac{1}{2}(65 - 29\sqrt{5})} \qquad (1)$$

$$s_2 = \tfrac{1}{2}\sqrt{27 - 12\sqrt{5}} \qquad (2)$$

$$s_3 = \tfrac{1}{2}\sqrt{\tfrac{1}{2}(25 - 11\sqrt{5})} \qquad (3)$$

$$s_4 = \sqrt{5} - 2 \qquad (4)$$

$$s_5 = \tfrac{1}{2}\sqrt{\tfrac{3}{2}(7 - 3\sqrt{5})} \qquad (5)$$

$$s_6 = \tfrac{1}{2}\sqrt{5 - 2\sqrt{5}} \qquad (6)$$

$$s_7 = \tfrac{1}{2}(3 - \sqrt{5}). \qquad (7)$$

The CIRCUMRADIUS is

$$R = \tfrac{1}{2}\sqrt{3}, \qquad (8)$$

and the SURFACE AREA and VOLUME are

$$S = 165\sqrt{5} - 360 \qquad (9)$$

$$V=\tfrac{1}{2}(55\sqrt{5}-120). \qquad (10)$$

Cube Dissection

A CUBE can be divided into n subcubes for only $n=1$, 8, 15, 20, 22, 27, 29, 34, 36, 38, 39, 41, 43, 45, 46, and $n \geq 48$ (Sloane's A014544).

The seven pieces used to construct the $3\times 3\times 3$ cube dissection known as the SOMA CUBE are one 3-POLYCUBE and six 4-POLYCUBES $(1\cdot 3+6\cdot 4=27)$, illustrated above.

Another $3\times 3\times 3$ cube dissection due to Steinhaus (1983) uses three 5-POLYCUBES and three 4-POLYCUBES $(3\cdot 5+3\cdot 4=27)$, illustrated above. There are two solutions.

It is possible to cut a 1×3 RECTANGLE into two identical pieces which will form a CUBE (without overlapping) when folded and joined. In fact, an INFINITE number of solutions to this problem were discovered by C. L. Baker (Hunter and Madachy 1975).

Lonke (2000) has considered the number $f(j,\ k,\ n)$ of j-dimensional faces of a random k-dimensional central section of the n-cube $B_\infty^n=[-1,\ 1]^n$, and gives the special result

$$f(0,\ k,\ n)=2^k\binom{n}{k}\sqrt{\frac{2k}{\pi}}\int_0^\infty e^{-kt^2/2}\gamma_{n-k}(tB_\infty^{n-k})\,dt,$$

where γ_{n-k} is the $(n-k)$-dimensional Gaussian probability measure.

Cube Duplication

Also called the Delian problem or Duplication of the cube. A classical problem of antiquity which, given the edge of a cube, requires a second cube to be constructed having double the volume of the first using only a straightedge and compass.

Under these restrictions, the problem cannot be solved because the Delian constant $2^{1/3}$ (the required ratio of sides of the original cube and that to be constructed) is not a Euclidean number. The problem can be solved, however, using a Neusis construction.

Cube Line Picking

The average distance between two points chosen at random inside a unit cube (the $n=3$ case of hypercube line picking) is

$$\Delta(3) = \tfrac{1}{105}[4 + 17\sqrt{2} - 6\sqrt{3} + 21\ln(1+\sqrt{2}) + 42\ln(2+\sqrt{3}) - 7\pi]$$

(Robbins 1978, Le Lionnais 1983).

Pick n points on a cube, and space them as far apart as possible. The best value known for the minimum straight line distance between any two points is given in the following table.

n	$d(n)$
5	1.1180339887498
6	1.0606601482100
7	1
8	1
9	0.86602540378463
10	0.74999998333331

11	0.70961617562351
12	0.70710678118660
13	0.70710678118660
14	0.70710678118660
15	0.625

Friedman, E. "Cubes in Cubes." http://www.stetson.edu/~efriedma/cubincub/.

Cube Point Picking

Pick N points $p_1, ..., p_N$ randomly in a unit n-cube. Let C be the CONVEX HULL, so

$$C \equiv \left\{ \sum_{j=1}^{N} \lambda_j p_j : \lambda_j \geq 0 \text{ for all } j \text{ and } \sum_{j=1}^{N} \lambda_j = 1 \right\}. \quad (1)$$

Let $V(n, N)$ be the expected n-D VOLUME (the CONTENT) of C, $S(n, N)$ be the expected $(n-1)$-D SURFACE AREA of C, and $P(n, N)$ the expected number of VERTICES on the POLYGONAL boundary of C. Then

$$\lim_{N\to\infty} \frac{N[1 - V(2, N)]}{\ln N} = \tfrac{8}{3}$$

$$\lim_{N\to\infty} \sqrt{N}[4 - S(2, N)]$$

$$= \sqrt{2\pi}\left[2 - \int_0^1 (\sqrt{1+t^2} - 1) t^{-3/2}\, dt\right]$$

$$= 4.2472965\ldots, \quad (2)$$

$$\lim_{N\to\infty} P(2, N) - \tfrac{8}{3}\ln N = \tfrac{8}{3}(\gamma - \ln 2)$$

$$= -0.309150708\ldots \quad (3)$$

(Rényi and Sulanke 1963, 1964).

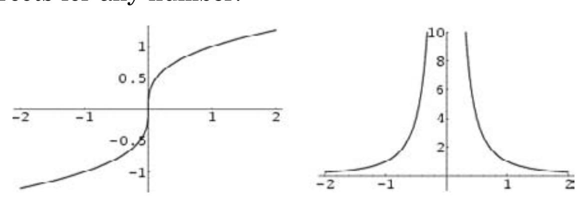
Cube Power

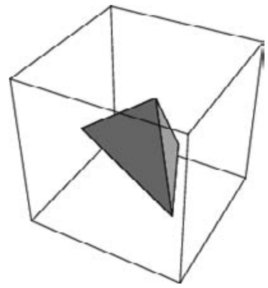
A number raised to the third POWER. x^3 is read as "x cubed."



See also CUBIC NUMBER

Cube Root

Given a number z, the cube root of z, denoted $\sqrt[3]{z}$ or $z^{1/3}$ (z to the 1/3 POWER), is a number a such that $a^3 = z$. There are three (not necessarily distinct) cube roots for any number.



For real arguments, the cube root is an INCREASING FUNCTION, although the usual derivative test cannot be used to establish this fact at the ORIGIN since the

derivative approaches infinity there (as illustrated above).

See also Cube Duplication, Cubed, Delian Constant, Geometric Problems of Antiquity, κ-Matrix, Square Root

Cube Tetrahedron Picking

Given four points chosen at random inside a unit cube, the average volume of the tetrahedron determined by these points is given by

$$\bar{V} = \frac{\overbrace{\int_0^1 \cdots \int_0^1}^{12} |V(\mathbf{x}_i)| dx_1 \cdots dx_4 dy_1 \cdots dy_4 dz_1 \cdots dz_4}{\underbrace{\int_0^1 \cdots \int_0^1 dx_1 \cdots dx_4 dy_1 \cdots dy_4 dz_1 \cdots dz_4}_{12}}$$

where the vertices are located at (x_i, y_i, z_i) where $i = 1, ..., 4$, and the (signed) volume is given by the determinant

$$V = \frac{1}{3!} \begin{vmatrix} x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \\ x_4 & y_4 & z_4 & 1 \end{vmatrix}.$$

The integral is extremely difficult to compute. The analytic result is not known, but numerically is given by $\bar{V} \approx 0.0138$. (Note that the result quoted in the reply to Seidov 2000 actually refers to the average volume for tetrahedron tetrahedron picking.)

Cubed

A number to the power 3 is said to be cubed, so that x^3 is called "x cubed."

See also Cube Root, Squared

Cubefree

A number is said to be cubefree if its prime factorization contains no tripled factors. All primes are therefore trivially cubefree. The cubefree numbers are 1, 2, 3, 4, 5, 6, 7, 9, 10, 11, 12, 13, 14, 15, 17, ... (Sloane's A004709). The cubeful numbers (i.e., those that contain at least one cube) are 8, 16, 24, 27, 32, 40, 48, 54, ... (Sloane's A046099). The number of cubefree numbers less than 10, 100, 1000, ... are 9, 85, 833, 8319, 83190, 831910, ..., and their asymptotic density is $1/\zeta(3) \approx 0.831907$, where $\zeta(n)$ is the Riemann zeta function.

Cubefree Part

That part of a positive integer left after all cubic factors are divided out. For example, the cubefree part of $24 = 2^3 \cdot 3$ is 3. For $n = 1, 2, ...$, the first few are 1, 2, 3, 4, 5, 6, 7, 1, 9, 10, 11, 12, 13, 14, 15, 2, ... (Sloane's A050985). The squarefree part function can be implemented in *Mathematica* as

```
SquarefreePart[n_Integer?Positive] :=
```

```
Times @@ Power @@@ ({#[[1]], Mod[#[[2]], 3]} &
/@ FactorInteger[n])
```

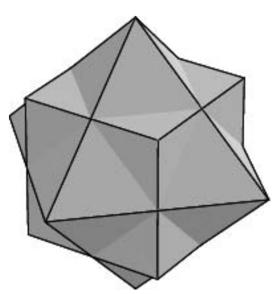
Cubefree Word

A cubefree word contains *no* cubed words as subwords. The number of binary cubefree words of length $n = 1$, 2, ... are 2, 4, 6, 10, 16, 24, 36, 56, 80, 118, ... (Sloane's A028445). Binary cubefree words satisfy

$$2 \cdot 1.080^n \leq c(n) \leq 2 \cdot 1.522^n. \qquad (1)$$



The number of ternary cubefree words of length $n = 1$, 2, ... are 3, 9, 24, 66, 180, 486, 1314, ... (Sloane's A051042). The number of quaternary cubefree words of length $n = 1$, 2, ... are 4, 16, 60, 228, 864, 3264, 12336, ... (Sloane's A051043).

Cube-Octahedron Compound

A POLYHEDRON COMPOUND composed of a CUBE and its DUAL POLYHEDRON, the OCTAHEDRON. For a CUBE of edge length 1, the 14 vertices are located at $(\pm 1/2, \pm 1/2, \pm 1/2)$, $(\pm 1, 0, 0)$, $(0, \pm 1, 0)$, $(0, 0, \pm 1)$. Since the edges of the cube and octahedron bisect each other, the resulting solid has side lengths 1/2 and $\sqrt{2/2}$, and SURFACE AREA and VOLUME given by

$$S = 3(1+\sqrt{3})$$

$$V = \tfrac{3}{2}.$$

The CONVEX HULL of the cube-octahedron compound is a RHOMBIC DODECAHEDRON.

The solid common to both the CUBE and OCTAHEDRON (left figure) in a cube-octahedron compound is a CUBOCTAHEDRON (middle figure). The edges intersecting in the points plotted above are the diagonals of RHOMBUSES, and the 12 RHOMBUSES form a RHOMBIC DODECAHEDRON (right figure; Ball and Coxeter 1987).

Cubic Close Packing

SPHERE PACKING

Cubic Curve

A cubic curve is an ALGEBRAIC CURVE of degree 3. An algebraic curve over a FIELD K is an equation $f(X, Y) = 0$, where $f(X, Y)$ is a POLYNOMIAL in X and Y with COEFFICIENTS in K, and the degree of f is the MAXIMUM degree of each of its terms (MONOMIALS).

Newton showed that all cubics can be generated by the projection of the five divergent cubic parabolas. Newton's classification of cubic curves appeared in the chapter "Curves" in *Lexicon Technicum* by John Harris published in London in 1710. Newton also classified all cubics into 72 types, missing six of them. In addition, he showed that any cubic can be obtained by a suitable projection of the ELLIPTIC CURVE

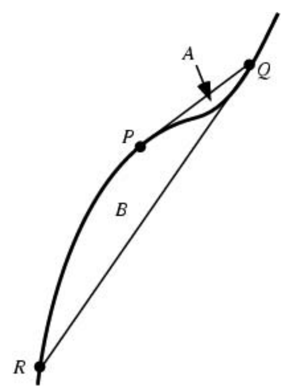
$$y^2 = ax^3 + bx^2 + cx + d, \qquad (1)$$

where the projection is a BIRATIONAL TRANSFORMA-

TION, and the general cubic can also be written as

$$y^2 = x^3 + ax + b. \quad (2)$$

Newton's first class is equations OF THE FORM



$$xy^2 + ey = ax^3 + bx^2 + cx + d. \quad (3)$$

This is the hardest case and includes the SERPENTINE CURVE as one of the subcases. The third class was

$$ay^2 = x(x^2 - 2bx + c), \quad (4)$$

which is called NEWTON'S DIVERGING PARABOLAS. Newton's 66th curve was the TRIDENT OF NEWTON. Newton's classification of cubics was criticized by Euler because it lacked generality. Plücker later gave a more detailed classification with 219 types.

The NINE ASSOCIATED POINTS THEOREM states that Any cubic curve that passes through eight of the nine intersections of two given cubic curves automatically passes through the ninth (Evelyn *et al.* 1974, p. 15).

Pick a point P, and draw the tangent to the curve at P. Call the point where this tangent intersects the curve Q. Draw another tangent and call the point of intersection with the curve R. Every curve of third degree has the property that, with the areas in the above labeled figure,

$$B = 16A \quad (5)$$

(Honsberger 1991).

Cubic Equation

A cubic equation is a POLYNOMIAL equation of degree three. Given a general cubic equation

$$z^3 + a_2 z^2 + a_1 z + a_0 = 0 \quad (1)$$

(the COEFFICIENT a_3 of z^3 may be taken as 1 without loss of generality by dividing the entire equation through by a_3), first attempt to eliminate the a_2 term by making a substitution OF THE FORM

$$z \equiv x - \lambda. \quad (2)$$

Then

$$(x-\lambda)^3 + a_2(x-\lambda)^2 + a_1(x-\lambda) + a_0 = 0 \quad (3)$$

$$(x^3 - 3\lambda x^2 + 3\lambda^2 x - \lambda^3) + a_2(x^2 - 2\lambda x + \lambda^2) + a_1(x-\lambda) + a_0 = 0 \quad (4)$$

$$x^3 + (a_2 - 3\lambda)x^2 + (a_1 - 2a_2\lambda + 3\lambda^2)x + (a_0 - a_1\lambda + a_2\lambda^2 - \lambda^3) = 0. \quad (5)$$

The x^2 is eliminated by letting $\lambda = a_2/3$, so

$$z \equiv x - \tfrac{1}{3}a_2. \quad (6)$$

Then

$$z^3 = (x - \tfrac{1}{3}a_2)^3 = x^3 - a_2 x^2 + \tfrac{1}{3}a_2^2 x - \tfrac{1}{27}a_2^3. \quad (7)$$

$$a_2 z^2 = a_2(x - \tfrac{1}{3}a_2)^2 = a_2 x^2 - \tfrac{2}{3}a_2^2 x + \tfrac{1}{9}a_2^3 \quad (8)$$

$$a_1 z = a_1(x - \tfrac{1}{3}a_2) = a_1 x - \tfrac{1}{3}a_1 a_2, \quad (9)$$

so equation (1) becomes

$$x^3 + (-a_2 + a_2)x^2 + (\tfrac{1}{3}a_2^2 - \tfrac{2}{3}a_2^2 + a_1)x - (\tfrac{1}{27}a_2^3 - \tfrac{1}{9}a_2^3 + \tfrac{1}{3}a_1 a_2 - a_0) = 0 \quad (10)$$

$$x^3 + (a_1 - \tfrac{1}{3}a_2^2)x - (\tfrac{1}{3}a_1 a_2 - \tfrac{2}{27}a_2^3 - a_0) = 0 \quad (11)$$

$$x^3 + 3 \cdot \frac{3a_1 - a_2^2}{9}x - 2 \cdot \frac{9a_1 a_2 - 27a_0 - 2a_2^3}{54} = 0. \quad (12)$$

Defining

$$p \equiv \frac{3a_1 - a_2^2}{3} \quad (13)$$

$$q \equiv \frac{9a_1 a_2 - 27a_0 - 2a_2^3}{27} \quad (14)$$

then allows (12) to be written in the standard form

$$x^3 + px = q. \quad (15)$$

The simplest way to proceed is to make VIETA'S

SUBSTITUTION

$$x = w - \frac{p}{3w}, \tag{16}$$

which reduces the cubic to the equation

$$w^3 - \frac{p^3}{27w^3} - q = 0, \tag{17}$$

which is easily turned into a QUADRATIC EQUATION in w^3 by multiplying through by w^3 to obtain

$$(w^3)^2 - q(w^3) - \tfrac{1}{27}p^3 = 0 \tag{18}$$

(Birkhoff and Mac Lane 1996, p. 106). The result from the QUADRATIC EQUATION is

$$\begin{aligned} w^3 &= \tfrac{1}{2}\left(q \pm \sqrt{q^2 + \tfrac{4}{27}p^3}\right) = \tfrac{1}{2}q \pm \sqrt{\tfrac{1}{4}q^2 + \tfrac{1}{27}p^3} \\ &= R \pm \sqrt{R^2 + Q^3}, \end{aligned} \tag{19}$$

where Q and R are sometimes more useful to deal with than are p and q. There are therefore six solutions for w (two corresponding to each sign for each ROOT of w^3). Plugging w back in to (17) gives three pairs of solutions, but each pair is equal, so there are three solutions to the cubic equation.

Equation (12) may also be explicitly factored by attempting to pull out a term OF THE FORM $(x - B)$ from the cubic equation, leaving behind a quadratic equation which can then be factored using the QUADRATIC FORMULA. This process is equivalent to making VIETA'S SUBSTITUTION, but does a slightly better job of motivating Vieta's "magic" substitution, and also at producing the explicit formulas for the solutions. First, define the intermediate variables

$$Q \equiv \frac{3a_1 - a_2^2}{9} \tag{20}$$

$$R \equiv \frac{9a_2a_1 - 27a_0 - 2a_2^3}{54} \tag{21}$$

(which are identical to p and q up to a constant factor). The general cubic equation (12) then becomes

$$x^3 + 3Qx - 2R = 0. \tag{22}$$

Let B and C be, for the moment, arbitrary constants. An identity satisfied by PERFECT CUBIC POLYNOMIAL equations is that

$$x^3 - B^3 = (x - B)(x^2 + Bx + B^2). \tag{23}$$

The general cubic would therefore be directly factorable if it did not have an x term (i.e., if $Q = 0$). However, since in general $Q \neq 0$, add a multiple of $(x - B)$—say $C(x - B)$—to both sides of (23) to give the slightly messy identity

$$\begin{aligned} (x^3 - B^3) + C(x - B) &= (x - B)(x^2 + Bx + B^2 + C) \\ &= 0, \end{aligned} \tag{24}$$

which, after regrouping terms, is

$$\begin{aligned} x^3 + Cx - (B^3 + BC) &= (x - B)[x^2 + Bx + (B^2 + C)] \\ &= 0. \end{aligned} \tag{25}$$

We would now like to match the COEFFICIENTS C and $-(B^3 + BC)$ with those of equation (22), so we must have

$$C = 3Q \tag{26}$$

$$B^3 + BC = 2R. \tag{27}$$

Plugging the former into the latter then gives

$$B^3 + 3QB = 2R. \tag{28}$$

Therefore, if we can find a value of B satisfying the above identity, we have factored a linear term from the cubic, thus reducing it to a QUADRATIC EQUATION. The trial solution accomplishing this miracle turns out to be the symmetrical expression

$$B = [R + \sqrt{Q^3 + R^2}]^{1/3} + [R - \sqrt{Q^3 + R^2}]^{1/3}. \tag{29}$$

Taking the second and third POWERS of B gives

$$\begin{aligned} B^2 &= [R + \sqrt{Q^3 + R^2}]^{2/3} + 2[R^2 - (Q^3 + R^2)]^{1/3} \\ &\quad + [R - \sqrt{Q^3 + R^2}]^{2/3} \\ &= [R + \sqrt{Q^3 + R^2}]^{2/3} + [R - \sqrt{Q^3 + R^2}]^{2/3} - 2Q \end{aligned} \tag{30}$$

$$\begin{aligned} B^3 &= -2QB \\ &\quad + \left\{[R + \sqrt{Q^3 + R^2}]^{1/3} + [R - \sqrt{Q^3 + R^2}]^{1/3}\right\} \\ &\quad \times \left\{[R + \sqrt{Q^3 + R^2}]^{2/3} + [R - \sqrt{Q^3 + R^2}]^{2/3}\right\} \\ &= [R + \sqrt{Q^3 + R^2}] + [R - \sqrt{Q^3 + R^2}] \\ &\quad + [R + \sqrt{Q^3 + R^2}]^{1/3}[R - \sqrt{Q^3 + R^2}]^{2/3} \\ &\quad + [R + \sqrt{Q^3 + R^2}]^{2/3}[R - \sqrt{Q^3 + R^2}]^{1/3} - 2QB \\ &= -2QB + 2R + [R^2 - (Q^3 + R^2)]^{1/3} \\ &\quad \times \left[\left(R + \sqrt{Q^3 + R^2}\right)^{1/3} + \left(R - \sqrt{Q^3 - R^2}\right)^{1/3}\right] \\ &= -2QB + 2R - QB = -3QB + 2R. \end{aligned} \tag{31}$$

Plugging B^3 and B into the left side of (28) gives

$$(-3QB + 2R) + 3QB = 2R, \tag{32}$$

so we have indeed found the factor $(x - B)$ of (22), and we need now only factor the quadratic part. Plugging $C = 3Q$ into the quadratic part of (25) and solving the resulting

$$x^2 + Bx + (B^2 + 3Q) = 0 \tag{33}$$

then gives the solutions

$$x = \tfrac{1}{2}\left[-B \pm \sqrt{B^2 - 4(B^2+3Q)}\right]$$
$$= -\tfrac{1}{2}B \pm \tfrac{1}{2}\sqrt{-3B^2-12Q}$$
$$= -\tfrac{1}{2}B \pm \tfrac{1}{2}\sqrt{3}i\sqrt{B^2+4Q}. \quad (34)$$

These can be simplified by defining

$$A \equiv \left[R+\sqrt{Q^3+R^2}\right]^{1/3} - \left[R-\sqrt{Q^3+R^2}\right]^{1/3} \quad (35)$$

$$A^2 = \left[R+\sqrt{Q^3+R^2}\right]^{2/3} - 2\left[R^2-(Q^3+R^2)\right]^{1/3}$$
$$+\left[R-\sqrt{Q^3+R^2}\right]^{2/3}$$
$$= \left[R+\sqrt{Q^3+R^2}\right]^{2/3} + \left[R-\sqrt{Q^3+R^2)}\right]^{2/3} + 2Q$$
$$= B^2+4Q, \quad (36)$$

so that the solutions to the quadratic part can be written

$$x = -\tfrac{1}{2}B \pm \tfrac{1}{2}\sqrt{3}iA. \quad (37)$$

Defining

$$D \equiv Q^3+R^2 \quad (38)$$

$$S \equiv \sqrt{R+\sqrt{D}} \quad (39)$$

$$T \equiv \sqrt{R-\sqrt{D}}, \quad (40)$$

where D is the DISCRIMINANT (which is defined slightly differently, including the opposite SIGN, by Birkhoff and Mac Lane 1996) then gives very simple expressions for A and B, namely

$$B = S+T \quad (41)$$

$$A = S-T. \quad (42)$$

Therefore, at last, the ROOTS of the original equation in z are then given by

$$z_1 = -\tfrac{1}{3}a_2 + (S+T) \quad (43)$$

$$z_2 = -\tfrac{1}{3}a_2 - \tfrac{1}{2}(S+T) + \tfrac{1}{2}i\sqrt{3}(S-T) \quad (44)$$

$$z_3 = -\tfrac{1}{3}a_2 - \tfrac{1}{2}(S+T) - \tfrac{1}{2}i\sqrt{3}(S-T), \quad (45)$$

with a_2 the COEFFICIENT of z^2 in the original equation, and S and T as defined above. These three equations giving the three ROOTS of the cubic equation are sometimes known as CARDANO'S FORMULA. Note that if the equation is in the standard form of Vieta

$$x^3+px = q, \quad (46)$$

in the variable x, then $a_2 = 0$, $a_1 = p$, and $a_0 = -q$, and the intermediate variables have the simple form (cf. Beyer 1987)

$$Q = \tfrac{1}{3}p \quad (47)$$

$$R = \tfrac{1}{2}q \quad (48)$$

$$D \equiv Q^3+R^2 = \left(\frac{p}{3}\right)^2 + \left(\frac{q}{2}\right)^2. \quad (49)$$

The solutions satisfy NEWTON'S RELATIONS

$$z_1+z_2+z_3 = -a_2 \quad (50)$$

$$z_1z_2+z_2z_3+z_1z_3 = a_1 \quad (51)$$

$$z_1z_2z_3 = -a_0. \quad (52)$$

In standard form (46), $a_2 = 0$, $a_1 = p$, and $a_0 = -q$, so eliminating q gives

$$p = -(z_i^2+z_iz_j+z_j^2) \quad (53)$$

for $i \neq j$, and eliminating p gives

$$q = -z_iz_j(z_i+z_j) \quad (54)$$

for $i \neq j$. In addition, the properties of the SYMMETRIC POLYNOMIALS appearing in NEWTON'S RELATIONS give

$$z_1^2+z_2^2+z_3^2 = -2p \quad (55)$$

$$z_1^3+z_2^3+z_3^3 = 3q \quad (56)$$

$$z_1^4+z_2^4+z_3^4 = 2p^2 \quad (57)$$

$$z_1^5+z_2^5+z_3^5 = -5pq. \quad (58)$$

The equation for z_1 in CARDANO'S FORMULA does not have an i appearing in it explicitly while z_2 and z_3 do, but this does not say anything about the number of REAL and COMPLEX ROOTS (since S and T are themselves, in general, COMPLEX). However, determining which ROOTS are REAL and which are COMPLEX can be accomplished by noting that if the DISCRIMINANT $D > 0$, one ROOT is REAL and two are COMPLEX CONJUGATES; if $D = 0$, all ROOTS are REAL and at least two are equal; and if $D < 0$, all ROOTS are REAL and unequal. If $D < 0$, define

$$\theta \equiv \cos^{-1}\left(\frac{R}{\sqrt{-Q^3}}\right). \quad (59)$$

Then the REAL solutions are OF THE FORM

$$z_1 = 2\sqrt{-Q}\cos\left(\frac{\theta}{3}\right) - \tfrac{1}{3}a_2 \quad (60)$$

$$z_2 = 2\sqrt{-Q}\cos\left(\frac{\theta+2\pi}{3}\right) - \tfrac{1}{3}a_2 \quad (61)$$

$$z_3 = 2\sqrt{-Q}\cos\left(\frac{\theta+4\pi}{3}\right) - \tfrac{1}{3}a_2. \quad (62)$$

This procedure can be generalized to find the REAL ROOTS for any equation in the standard form (46) by

using the identity

$$\sin^3\theta - \tfrac{3}{4}\sin\theta + \tfrac{1}{4}\sin(3\theta) = 0 \quad (63)$$

(Dickson 1914) and setting

$$x \equiv \sqrt{\frac{4|p|}{3}}\, y \quad (64)$$

(Birkhoff and Mac Lane 1996, pp. 90–1), then

$$\left(\frac{4|p|}{3}\right)^{3/2} y^3 + p\sqrt{\frac{4|p|}{3}}\, y = q \quad (65)$$

$$y^3 + \tfrac{3}{4}\frac{p}{|p|}\, y = \left(\frac{3}{4|p|}\right)^{3/2} q \quad (66)$$

$$4y^3 + 3\,\mathrm{sgn}(p) y = \tfrac{1}{2} q \left(\frac{3}{|p|}\right)^{3/2} \equiv C. \quad (67)$$

If $p > 0$, then use

$$\sinh(3\theta) = 4\sinh^3\theta + 3\sinh\theta \quad (68)$$

to obtain

$$y = \sinh(\tfrac{1}{3}\sinh^{-1} C). \quad (69)$$

If $p < 0$ and $|C| \geq 1$, use

$$\cosh(3\theta) = 4\cosh^3\theta - 3\cosh\theta, \quad (70)$$

and if $p < 0$ and $|C| \leq 1$, use

$$\cos(3\theta) = 4\cos^3\theta - 3\cos\theta, \quad (71)$$

to obtain

$$y = \begin{cases} \cosh(\tfrac{1}{3}\cosh^{-1} C) & \text{for } C \geq 1 \\ -\cosh(\tfrac{1}{3}\cosh^{-1}|C|) & \text{for } C \leq -1 \\ \cos(\tfrac{1}{3}\cos^{-1} C) & \text{for } |C| < 1. \end{cases} \quad (72)$$

The solutions to the original equation are then

$$x_i = 2\sqrt{\frac{|p|}{3}}\, y_i - \tfrac{1}{3} a_2. \quad (73)$$

An alternate approach to solving the cubic equation is to use LAGRANGE RESOLVENTS (Faucette 1996). Let $\omega \equiv e^{2\pi i/3}$, define

$$(1,\ x_1) = x_1 + x_2 + x_3 \quad (74)$$

$$(\omega,\ x_1) = x_1 + \omega x_2 + \omega^2 x_3 \quad (75)$$

$$(\omega^2,\ x_1) = x_1 + \omega^2 x_2 + \omega x_3, \quad (76)$$

where x_i are the ROOTS of

$$x^3 + px - q = 0, \quad (77)$$

and consider the equation

$$[x - (u_1 + u_2)][x - (\omega u_1 + \omega^2 u_2)][x - (\omega^2 u_1 + \omega u_2)] = 0, \quad (78)$$

where u_1 and u_2 are COMPLEX NUMBERS. The ROOTS are then

$$x_j = \omega^j u_1 + \omega^{2j} u_2 \quad (79)$$

for $j = 0$, 1, 2. Multiplying through gives

$$x^3 - 3u_1u_2x - (u_1^3 + u_2^3) = 0, \quad (80)$$

which can be written in the form (77), where

$$u_1^3 + u_2^3 = q \quad (81)$$

$$u_1^3 u_2^3 = -\left(\frac{p}{3}\right)^3. \quad (82)$$

Some curious identities involving the roots of a cubic equation due to Ramanujan are given by Berndt (1994).

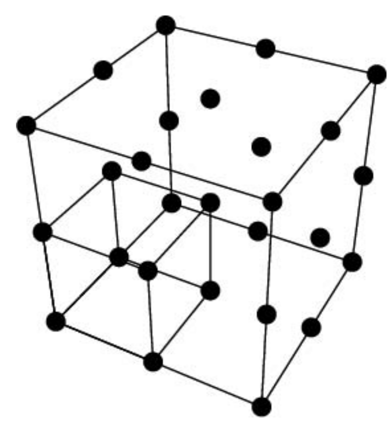
Cubic Graph

K_4 $K_{3,3}$ $Ci_{1,3}(6)$

Cubic graphs, also called trivalent graphs, are graphs all of whose nodes have degree 3 (i.e., 3-REGULAR GRAPHS). Cubic graphs on n nodes exists only for even n (Harary 1994, p. 15). The numbers of cubic graphs on 2, 4, 6, ... nodes are 0, 1, 2, 6, 21, 94, 540, 4207, ... (Sloane's A005638). The unique 4-node cubic graph is the COMPLETE GRAPH k_4. The two 6-node cubic graphs are the UTILITY GRAPH $K_{3,\ 3}$ and the CIRCULANT GRAPH $Ci_{1,\ 3}(6)$. The connected 3-regular graphs have been determined by Brinkmann (1996) up to 24 nodes.
(3, g)-CAGE GRAPHS and UNITRANSITIVE GRAPHS are cubic. In addition, the following tables gives polyhedra whose SKELETONS are cubic.



POLYHEDRON	nodes
TETRAHEDRON	4
CUBE	8
TRUNCATED TETRAHEDRON	12
DODECAHEDRON	20
TRUNCATED CUBE	24
TRUNCATED OCTAHEDRON	24
GREAT RHOMBICUBOCTAHEDRON (ARCHIMEDEAN)	48
TRUNCATED ICOSAHEDRON	60
GREAT RHOMBICOSIDODECAHEDRON (ARCHIMEDEAN)	120

Cubic Number

A FIGURATE NUMBER OF THE FORM n^3, for n a POSITIVE INTEGER. The first few are 1, 8, 27, 64, ... (Sloane's A000578). The GENERATING FUNCTION giving the cubic numbers is

$$\frac{x(x^2+4x+1)}{(x-1)^4} = x + 8x^2 + 27x^3 + \ldots \qquad (1)$$

The HEX PYRAMIDAL NUMBERS are equivalent to the cubic numbers (Conway and Guy 1996).

As a part of the study of WARING'S PROBLEM, it is known that every positive integer is a sum of no more than 9 *positive* cubes ($g(3)=9$, proved by Dickson, Pillai, and Niven in the early twentieth century), that every "sufficiently large" integer is a sum of no more than 7 positive cubes ($G(3) \le 7$). However, it is not known if 7 can be reduced (Wells 1986, p. 70). The number of *positive* cubes needed to represent the numbers 1, 2, 3, ... are 1, 2, 3, 4, 5, 6, 7, 1, 2, 3, 4, 5, 6, 7, 8, 2, ...(Sloane's A002376), and the number of distinct ways to represent the numbers 1, 2, 3, ... in

terms of positive cubes are 1, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, 3, 4, 4, 4, 5, 5, 5, 5, ... (Sloane's A003108).

In 1939, Dickson proved that the only INTEGERS requiring nine positive cubes are 23 and 239. Wieferich proved that only 15 INTEGERS require eight cubes: 15, 22, 50, 114, 167, 175, 186, 212, 213, 238, 303, 364, 420, 428, and 454 (Sloane's A018889). The quantity $G(3)$ in WARING'S PROBLEM therefore satisfies $G(3) \leq 7$, and the largest number known requiring seven cubes is 8042. Deshouillers *et al.* (1999) conjectured that 7,373,170,279,850 is the largest integer that cannot be expressed as the sum of four nonnegative cubes.

The following table gives the first few numbers which require *at least* $N = 1, 2, 3, ..., 9$ (i.e., N or more) positive cubes to represent them as a sum.

N	Sloane	Numbers
1	Sloane's A000578	1, 8, 27, 64, 125, 216, 343, 512, ...
2	Sloane's A003325	2, 9, 16, 28, 35, 54, 65, 72, 91, ...
3	Sloane's A003072	3, 10, 17, 24, 29, 36, 43, 55, 62, ...
4	Sloane's A003327	4, 11, 18, 25, 30, 32, 37, 44, 51, ...
5	Sloane's A003328	5, 12, 19, 26, 31, 33, 38, 40, 45, ...
6	Sloane's A003329	6, 13, 20, 34, 39, 41, 46, 48, 53, ...
7	Sloane's A018890	7, 14, 21, 42, 47, 49, 61, 77, ...
8	Sloane's A018889	15, 22, 50, 114, 167, 175, 186, ...
9	Sloane's A018888	23, 239

There is a finite set of numbers which cannot be expressed as the sum of *distinct positive* cubes: 2, 3, 4, 5, 6, 7, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, ...(Sloane's A001476).

It is known that every integer is a sum of at most 5 signed cubes ($eg(3) \leq 5$ in WARING'S PROBLEM). It is *believed* that 5 can be reduced to 4, so that

$$N = A^3 + B^3 + C^3 + D^3 \tag{2}$$

for any number N, although this has not been proved for numbers OF THE FORM $9n \pm 4$. However, every multiple of 6 can be REPRESENTED AS a sum of four signed cubes as a result of the algebraic identity

$$6x = (x+1)^3 + (x-1)^3 - x^3 - x^3. \tag{3}$$

In fact, all numbers $N < 1000$ and *not* OF THE FORM $9n \pm 4$ are known to be expressible as the SUM

$$N = A^3 + B^3 + C^3 \tag{4}$$

of *three* (positive or negative) cubes with the exception of $N = 30$, 33, 42, 52, 74, 110, 114, 156, 165, 195, 290, 318, 366, 390, 420, 444, 452, 478, 501, 530, 534, 564, 579, 588, 600, 606, 609, 618, 627, 633, 732, 735, 758, 767, 786, 789, 795, 830, 834, 861, 894, 903, 906, 912, 921, 933, 948, 964, 969, and 975 (Sloane's A046041; Miller and Woollett 1955; Gardiner *et al.* 1964; Guy 1994, p. 151). While it is known that (4) has no solutions for N of the form $9n \pm 4$ (Hardy and Wright 1979, p. 327), there is known reason for excluding the above integers (Gardiner *et al.* 1964). Mahler proved that 1 has infinitely-many representations as 3 signed cubes.

The following table gives the numbers which can be represented in *exactly* W different ways as a sum of N positive cubes. (Combining all Ws for a given N then gives the sequences in the previous table.) For example,

$$157 = 4^3 + 4^3 + 3^3 + 1^3 + 1^3 = 5^3 + 2^3 + 2^3 + 2^3 + 2^3 \tag{5}$$

can be represented in $W = 2$ ways by $N = 5$ cubes. The smallest number representable in $W = 2$ ways as a sum of $N = 2$ cubes,

$$1729 = 1^3 + 12^3 = 9^3 + 10^3, \tag{6}$$

is called the HARDY-RAMANUJAN NUMBER and has special significance in the history of mathematics as a result of a story told by Hardy about Ramanujan. Note that Sloane's A001235 is defined as the sequence of numbers which are the sum of cubes in *two or more* ways, and so appears identical in the first few terms to the ($N = 2$, $W = 2$) series given below.

N	W	Sloane	numbers
1	0	A007412	2, 3, 4, 5, 6, 7, 9, 10, 11, 12, 13, 14, ...
1	1	A000578	1, 8, 27, 64, 125, 216, 343, 512, ...
2	0	A057903	1, 3, 4, 5, 6, 7, 8, 10, 11, 12, 13, 14, ...
2	1		2, 9, 16, 28, 35, 54, 65, 72, 91, ...

6	0	A057907	1, 2, 3, 4, 5, 7, 8, 9, 10, 11, 12, 14, 15, ...
6	1	A048929	6, 13, 20, 27, 32, 34, 39, 41, 46, ...
6	2	A048930	158, 165, 184, 221, 228, 235, 247, ...
6	3	A048931	221, 254, 369, 411, 443, 469, 495, ...

The following table gives the possible residues (mod n) for cubic numbers for $n = 1$ to 20, as well as the number of distinct residues $s(n)$.

n	$s(n)$	$x^3 \pmod{n}$
2	2	0, 1
3	3	0, 1, 2
4	3	0, 1, 3
5	5	0, 1, 2, 3, 4
6	6	0, 1, 2, 3, 4, 5
7	3	0, 1, 6
8	5	0, 1, 3, 5, 7
9	3	0, 1, 8
10	10	0, 1, 2, 3, 4, 5, 6, 7, 8, 9
11	11	0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10
12	9	0, 1, 3, 4, 5, 7, 8, 9, 11
13	5	0, 1, 5, 8, 12
14	6	0, 1, 6, 7, 8, 13
15	15	0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14
16	10	0, 1, 3, 5, 7, 8, 9, 11, 13, 15
17	17	0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16
18	6	0, 1, 8, 9, 10, 17
19	7	0, 1, 7, 8, 11, 12, 18
20	15	0, 1, 3, 4, 5, 7, 8, 9, 11, 12, 13, 15, 16, 17, 19

Dudeney found two RATIONAL NUMBERS other than 1 and 2 whose cubes sum to 9,

$$\frac{415280564497}{348671682660} \text{ and } \frac{676702467503}{348671682660} \tag{7}$$

(Gardner 1958). The problem of finding two RATIONAL NUMBERS whose cubes sum to six was "proved" impossible by Legendre. However, Dudeney found the simple solutions 17/21 and 37/21.

The only three consecutive INTEGERS whose cubes sum to a cube are given by the DIOPHANTINE EQUATION

$$3^3 + 4^3 + 5^3 = 6^3. \tag{8}$$

CATALAN'S CONJECTURE states that 8 and 9 (2^3 and 3^2) are the only consecutive POWERS (excluding 0 and 1), i.e., the only solution to CATALAN'S DIOPHANTINE PROBLEM. This CONJECTURE has not yet been proved or refuted, although R. Tijdeman has proved that there can be only a finite number of exceptions should the CONJECTURE not hold. It is also known that 8 and 9 are the only consecutive cubic and SQUARE NUMBERS (in either order).

There are six POSITIVE INTEGERS equal to the sum of the DIGITS of their cubes: 1, 8, 17, 18, 26, and 27 (Sloane's A046459; Moret Blanc 1879). There are four POSITIVE INTEGERS equal to the sums of the cubes of their digits:

$$153 = 1^3 + 5^3 + 3^3 \tag{9}$$

$$370 = 3^3 + 7^3 + 0^3 \tag{10}$$

$$371 = 3^3 + 7^3 + 1^3 \tag{11}$$

$$407 = 4^3 + 0^3 + 7^3 \tag{12}$$

(Ball and Coxeter 1987). There are two SQUARE

NUMBERS OF THE FORM n^3-4 : $4=2^3-4$ and $121=5^3-4$ (Le Lionnais 1983). A cube cannot be the concatenation of two cubes, since if c^3 is the concatenation of a^3 and b^3, then $c^3=10^k a^3+b^3$, where k is the number of digits in b^3. After shifting any powers of 1000 in 10^k into a^3, the original problem is equivalent to finding a solution to one of the DIOPHANTINE EQUATIONS

$$c^3-b^3=a^3 \quad (13)$$

$$c^3-b^3=10a^3 \quad (14)$$

$$c^3-b^3=100a^3. \quad (15)$$

None of these have solutions in integers, as proved independently by Sylvester, Lucas, and Pepin (Dickson 1966, pp. 572–78).

Cubic Reciprocity Theorem

A RECIPROCITY THEOREM for the case $n=3$ solved by Gauss using "INTEGERS" OF THE FORM $a+b\rho$, when ρ is a root of $x^2+x+1=0$ (i.e., ρ equals $-(-1)^{1/3}$ or $(-1)^{2/3}$) and a, b are INTEGERS.

Cubic Residue

If there is an INTEGER x such that

$$x^3 \equiv q \pmod{p}, \quad (1)$$

then q is said to be a cubic residue (mod p). If not, q is said to be a cubic nonresidue (mod p).

References

Nagell, T. *Introduction to Number Theory.* New York: Wiley, p. 115, 1951.

Cubic Spline

A cubic spline is a SPLINE constructed of piecewise third-order POLYNOMIALS which pass through a set of control points. The second DERIVATIVE of each POLYNOMIAL is commonly set to zero at the endpoints, since this provides a boundary condition that completes the system of $n-2$ equations, leading to a simple 3-diagonal system which can be solved easily to give the coefficients of the polynomials. However, this choice is not the only one possible, and other boundary conditions can be used instead.

Cubic Surface

An ALGEBRAIC SURFACE of ORDER 3. Schläfli and Cayley classified the singular cubic surfaces. On the general cubic, there exists a curious geometrical structure called DOUBLE SIXES, and also a particular arrangement of 27 (possibly complex) lines, as discovered by Schläfli (Salmon 1965, Fischer 1986) and sometimes called SOLOMON'S SEAL LINES. A nonregular cubic surface can contain 3, 7, 15, or 27 real lines (Segre 1942, Le Lionnais 1983). The CLEBSCH DIAGONAL CUBIC contains all possible 27. The maximum number of ORDINARY DOUBLE POINTS on a cubic surface is four, and the unique cubic surface having four ORDINARY DOUBLE POINTS is the CAYLEY CUBIC.

Schoutte (1910) showed that the 27 lines can be put into a ONE-TO-ONE correspondence with the vertices of a particular POLYTOPE in 6-D space in such a manner that all incidence relations between the lines are mirrored in the connectivity of the POLYTOPE and conversely (Du Val 1931). A similar correspondence can be made between the 28 bitangents of the general plane QUARTIC CURVE and a 7-D POLYTOPE (Coxeter 1928) and between the tritangent planes of the canonical curve of genus 4 and an 8-D POLYTOPE (Du Val 1933).

A smooth cubic surface contains 45 TRITANGENTS (Hunt). The Hessian of smooth cubic surface contains at least 10 ORDINARY DOUBLE POINTS, although the Hessian of the CAYLEY CUBIC contains 14 (Hunt).

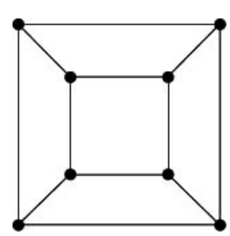
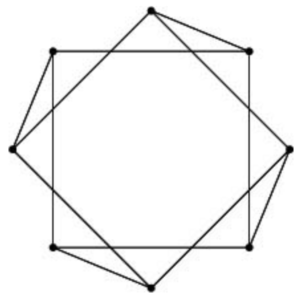
Cubical Conic Section

CUBICAL ELLIPSE, CUBICAL HYPERBOLA, CUBICAL PARABOLA, SKEW CONIC

Cubical Ellipse



An equation OF THE FORM



$$y = ax^3 + bx^2 + cx + d$$

where only one ROOT is real.

See also CUBICAL CONIC SECTION, CUBICAL HYPERBOLA, CUBICAL PARABOLA, CUBICAL PARABOLIC HYPERBOLA, ELLIPSE, SKEW CONIC

Cubical Graph

The PLATONIC GRAPH corresponding to the connectivity of the CUBE. Several symmetrical circular embeddings of this graph are illustrated in the second figure above. The cubical graph has 8 nodes, 12 edges, VERTEX CONNECTIVITY 3, and EDGE CONNECTIVITY 3, GRAPH DIAMETER 3, GRAPH RADIUS 3, and GIRTH 4. The cubical graph's CHROMATIC POLYNOMIAL is

$$\pi_G(z) = z^8 - 12z^7 + 66z^6 - 214z^5 + 441z^4 - 572z^3 + 423z^2 - 133z,$$

and the CHROMATIC NUMBER is $\chi(G) = 2$.

The maximum number of nodes in a cubical graph which induce a cycle is six (Danzer and Klee 1967; Skiena 1990, p. 149).

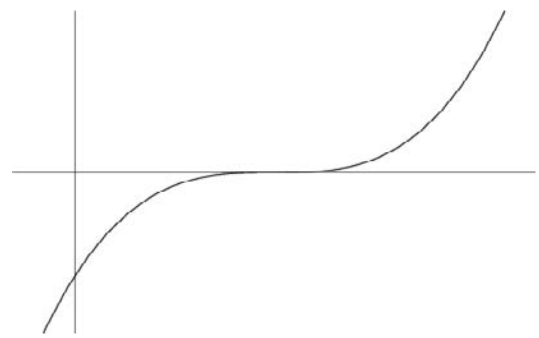
Cubical Hyperbola

An equation OF THE FORM



$$y = ax^3 + bx^2 + cx + d,$$

where the three ROOTS are REAL and distinct, i.e.,

$$y = a(x - r_1)(x - r_2)(x - r_3)$$
$$= a[x^3 - (r_1 + r_2 + r_3)x^2 + (r_1r_2 + r_1r_3 + r_2r_3)x - r_1r_2r_3].$$

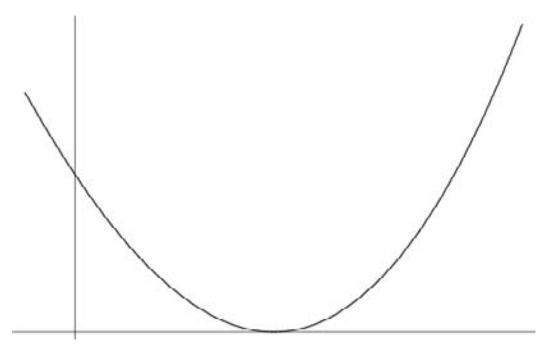
See also CUBICAL CONIC SECTION, CUBICAL ELLIPSE, CUBICAL HYPERBOLA, CUBICAL PARABOLA, HYPERBOLA

Cubical Parabola

An equation OF THE FORM

$$y = ax^3 + bx^2 + cx + d,$$

where the three ROOTS of the equation coincide (and are therefore real), i.e.,



$$y = a(x - r)^3 = a(x^3 - 3rx^2 - 3r^2x - r^3).$$

See also CUBICAL CONIC SECTION, CUBICAL ELLIPSE, CUBICAL HYPERBOLA, CUBICAL PARABOLIC HYPERBOLA, PARABOLA, SEMICUBICAL PARABOLA

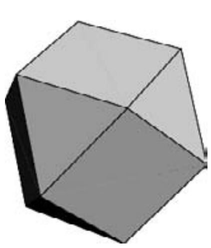
Cubicuboctahedron

GREAT CUBICUBOCTAHEDRON, SMALL CUBICUBOCTAHEDRON

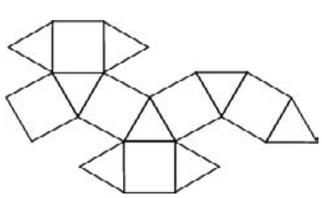
Cubique d'Agnesi

WITCH OF AGNESI

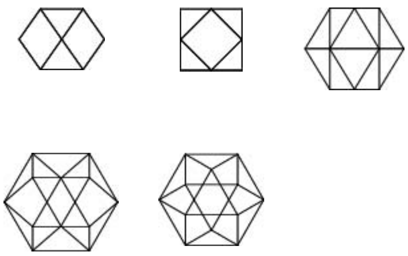
Cubitruncated Cuboctahedron



The UNIFORM POLYHEDRON U_{16} whose DUAL is the TETRADYAKIS HEXAHEDRON. It has WYTHOFF SYMBOL $3\frac{4}{3}\,4|$. Its faces are $8\{6\} + 6\{8\} + 6\{\frac{8}{3}\}$. It is a FACETED OCTAHEDRON. the CIRCUMRADIUS for a cubitruncated cuboctahedron of unit edge length is



$$r = \tfrac{1}{2}\sqrt{7}.$$



References

Wenninger, M. J. *Polyhedron Models.* Cambridge, England: Cambridge University Press, pp. 113–14, 1971.

Cuboctahedron

The ARCHIMEDEAN SOLID A_1 (also called the DYMAXION or HEPTAPARALLELOHEDRON) with faces $8\{3\} + 6\{4\}$. It is one of the two convex QUASIREGULAR POLYHEDRA. It is UNIFORM POLYHEDRON U_7 and Wenninger model W_{11}. It has SCHLÄFLI SYMBOL $\left\{ \begin{smallmatrix} 3 \\ 4 \end{smallmatrix} \right\}$ and WYTHOFF SYMBOL $2\,|\,34$.

The DUAL POLYHEDRON is the RHOMBIC DODECAHEDRON. The cuboctahedron has the O_h OCTAHEDRAL GROUP of symmetries. According to Heron, Archimedes ascribed the cuboctahedron to Plato (Heath 1981; Coxeter 1973, p. 30). The VERTICES of a cuboctahedron with EDGE length of $\sqrt{2}$ are $(0, \pm 1, \pm 1)$, $(\pm 1, 0, \pm 1)$, and $(\pm 1, \pm 1, 0)$.

The INRADIUS r of the dual, MIDRADIUS ρ of the solid and dual, and CIRCUMRADIUS R of the solid for $a = 1$ are

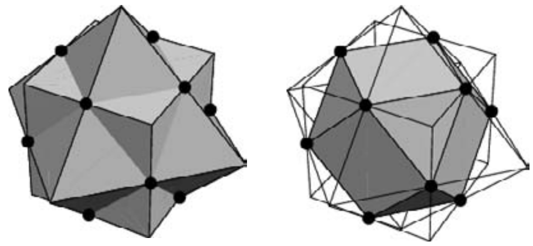
$$r = \tfrac{3}{4} = 0.75 \quad (1)$$

$$\rho = \tfrac{1}{2}\sqrt{3} \approx 0.86602 \quad (2)$$

$$R = 1. \quad (3)$$

The distances from the center of the solid to the centroids of the triangular and square faces are

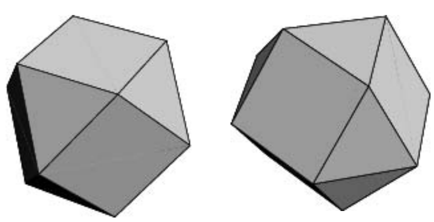
$$r_3 = \tfrac{1}{3}\sqrt{6} \quad (4)$$



$$r_4 = \tfrac{1}{2}\sqrt{2}. \quad (5)$$

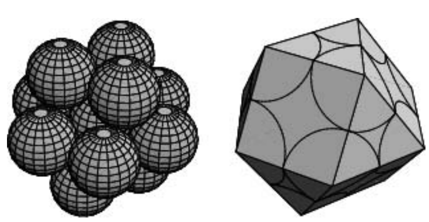
The SURFACE AREA and VOLUME are

$$S = 6 + 2\sqrt{3} \quad (6)$$



$$V = \tfrac{5}{3}\sqrt{2}. \quad (7)$$

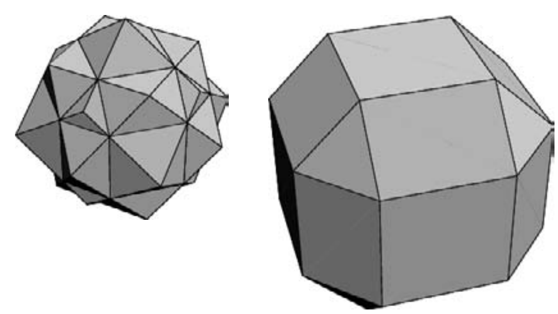
FACETED versions of the cuboctahedron include the CUBOHEMIOCTAHEDRON and OCTAHEMIOCTAHEDRON.



The solid common to both the CUBE and OCTAHEDRON (left figure) in a CUBE-OCTAHEDRON COMPOUND is a CUBOCTAHEDRON (right figure; Ball and Coxeter 1987). The mineral argentite (Ag_2S) forms cuboctahedral crystals (Steinhaus 1983, p. 203). The cuboctahedron can be inscribed in the RHOMBIC DODECAHEDRON (Steinhaus 1983, p. 206).

Wenninger (1989) lists four of the possible STELLATIONS of the cuboctahedron: the CUBE-OCTAHEDRON COMPOUND, a truncated form of the STELLA OCTANGULA, a sort of compound of six intersecting square pyramids, and an attractive concave solid formed of rhombi meeting four at a time.

If a cuboctahedron is oriented with triangles on top and bottom, the two halves may be rotated one sixth of a turn with respect to each other to obtain JOHNSON SOLID J_{27}, the TRIANGULAR ORTHOBICUPOLA.



In cubic close packing, each sphere is surrounded by 12 other spheres. Taking a collection of 13 such spheres gives the cluster illustrated above. Connecting the centers of the external 12 spheres gives a cuboctahedron (Steinhaus 1983, pp. 203–07), which is therefore also a SPACE-FILLING POLYHEDRON.

Cuboctahedron-Rhombic Dodecahedron Compound

The POLYHEDRON COMPOUND consisting of the CUBOCTAHEDRON and its dual, the RHOMBIC DODECAHEDRON, illustrated in the left figure above. The right figure shows the solid common to the two polyhedra. If the CUBOCTAHEDRON has unit edge length, the compound can be constructed by midpoint CUMULATION with heights

$$h_3 = \tfrac{1}{4}\sqrt{6} \tag{1}$$

$$h_4 = \tfrac{1}{2}\sqrt{2}. \tag{2}$$

The resulting compound has side lengths

$$s_1 = \tfrac{1}{8}\sqrt{6} \tag{3}$$

$$s_2 = \tfrac{1}{2} \tag{4}$$

$$s_3 = \tfrac{1}{4}\sqrt{6} \tag{5}$$

$$s_4 = \tfrac{1}{2}\sqrt{2}, \quad (6)$$

and SURFACE AREA and VOLUME

$$S = \tfrac{3}{4}(4 + 5\sqrt{2} + 2\sqrt{3}) \quad (7)$$

$$V = \tfrac{31}{16}\sqrt{2}. \quad (8)$$

Cuboid

A rectangular PARALLELEPIPED, sometimes also called a brick. A cuboid of side lengths a, b, and c has VOLUME

$$V = abc \quad (1)$$

and SURFACE AREA

$$S = 2(ab + ac + bc). \quad (2)$$

The face diagonals are

$$d_{ab} = \sqrt{a^2 + b^2} \quad (3)$$

$$d_{ac} = \sqrt{a^2 + c^2} \quad (4)$$

$$d_{bc} = \sqrt{b^2 + c^2} \quad (5)$$

and the body diagonal is

$$d_{abc} = \sqrt{a^2 + b^2 + c^2}. \quad (6)$$

A cuboid with all sides equal is called a CUBE.

Cullen Number

A number OF THE FORM

$$C_n = 2^n n + 1.$$

The first few are 3, 9, 25, 65, 161, 385, ... (Sloane's A002064). Cullen numbers are DIVISIBLE by $p = 2n - 1$ if p is a PRIME OF THE FORM $8k \pm 3$.

The only Cullen numbers C_n for $n < 300,000$ which are PRIME are for $n = 1$, 141, 4713, 5795, 6611, 18496, 32292, 32469, 59656, 90825, 262419, ... (Sloane's A005849; Ballinger). The largest PRIME Cullen number known is for $n = 361275$, but the range 335000–45000 has not yet been fully checked.

Cumulant

Let $\phi(t)$ be the CHARACTERISTIC FUNCTION, defined as the FOURIER TRANSFORM of the PROBABILITY DENSITY

FUNCTION (*using* FOURIER TRANSFORM *parameters* $a=b=1$),

$$\phi(t)=\mathcal{F}[P(x)]=\int_{-\infty}^{\infty} e^{itx}P(x)\,dx. \tag{1}$$

Then the cumulants κ_n are then defined by

$$\ln \phi(t) \equiv \sum_{n=0}^{\infty} k_n \frac{(it)^n}{n!} \tag{2}$$

(Abramowitz and Stegun 1972, p. 928). Taking the MACLAURIN SERIES gives

$$\begin{aligned}\ln \phi(t) &= (it)\mu_1' + \frac{1}{2}(it)^2(\mu_2' - \mu_1'^2) + \frac{1}{3!}(it)^3 \\ &\times (2\mu_1'^3 - 3\mu_1'\mu_2' + \mu_3') + \tfrac{1}{4!}(it)^4 \\ &\times (-6\mu_1'^4 + 12\mu_1'^2\mu_2' - 3\mu_2'^2 - 4\mu_1'\mu_3' + \mu_4') + \frac{1}{5!} \\ &\times (it)^5 \\ &\times [24\mu_1'^5 - 60\mu_1'^3\mu_2' + 20\mu_1'^2\mu_3' - 10\mu_2'\mu_3' \\ &+ 5\mu_1'(6\mu_2'^2 - \mu_4') + \mu_5'] + \ldots,\end{aligned} \tag{3}$$

where $\mu_n{}'$ are RAW MOMENTS, so

$$\kappa_1 = \mu_1' \tag{4}$$

$$\kappa_2 = \mu_2' - \mu_1' \tag{5}$$

$$\kappa_3 = 2\mu_1'^3 - 3\mu_1'\mu_2' + \mu_3' \tag{6}$$

$$\kappa_4 = -6\mu_1'^4 + 12\mu_1'^2\mu_2' - 3\mu_2'^2 - 4\mu_1'\mu_3' + \mu_4' \tag{7}$$

$$\begin{aligned}\kappa_5 &= -24\mu_1'^5 - 60\mu_1'^3\mu_2' + 20\mu_1'^2\mu_3' - 10\mu_2'\mu_3' \\ &+ 5\mu_1'(6\mu_2'^2 - \mu_4') + \mu_5'.\end{aligned} \tag{8}$$

In terms of the CENTRAL MOMENTS μ_n,

$$\kappa_1 = \mu \tag{9}$$

$$\kappa_2 = \mu_2 = \sigma^2 \tag{10}$$

$$\kappa_3 = \mu_3 \tag{11}$$

$$\kappa_4 = \mu_4 - 3\mu_2^2 \tag{12}$$

$$\kappa_5 = \mu_5 - 10\mu_2\mu_3, \tag{13}$$

where μ is the MEAN and $\sigma^2 \equiv \mu_2$ is the VARIANCE.

The k-STATISTIC are UNBIASED ESTIMATORS of the cumulants.

See also CHARACTERISTIC FUNCTION (PROBABILITY), CUMULANT-GENERATING FUNCTION, k-STATISTIC, KURTOSIS, MEAN, MOMENT, SHEPPARD'S CORRECTION, SKEWNESS, UNBIASED ESTIMATOR, VARIANCE

Cumulant-Generating Function

Let $M(h)$ be the MOMENT-GENERATING FUNCTION, then

$$K(h) \equiv \ln M(h) = \kappa_1 h + \frac{1}{2!} h^2\kappa_2 + \frac{1}{3!} h^3\kappa_3 + \ldots, \tag{1}$$

where κ_1, κ_2, ..., are the CUMULANTS.

If

$$L = \sum_{j=1}^{N} c_j x_j \tag{2}$$

is a function of N independent variables, then the cumulant-generating function for L is given by

$$K(h) = \sum_{j=1}^{N} K_j(c_j h). \tag{3}$$

See also CUMULANT, MOMENT-GENERATING FUNCTION

References

Cumulation

The dual operation of TRUNCATION which replaces the faces of a POLYHEDRON with PYRAMIDS of height h (where h may be positive, zero, or negative) having the face as the base. This operation is implemented in *Mathematica* under the misnomer `Stellate[`*poly*, *ratio*`]` in the *Mathematica* add-on package `Graphics`Polyhedra`` (which can be loaded with the command `<<Graphics``). The operation is sometimes also called accretion, or sometimes akisation (since it transforms a regular polygon to an n-akis polyhedron, i.e., quadruples the number of faces).

The following plots show cumulation series for the TETRAHEDRON, CUBE, OCTAHEDRON, DODECAHEDRON, and ICOSAHEDRON.

Cumulation with $h=0$ gives a triangulated version of the original solid. The following table gives special solids formed by cumulation of given heights on simple solids. In this table, r is the INRADIUS, and $(r+h)/h$ is the "stellation ratio" as defined in *Mathematica*.

Original	h	$(r+h)/h$	Result
CUBE	$\frac{1}{6}$	$4/3$	TETRAKIS HEXAHEDRON
CUBE	$\frac{1}{2}$	2	RHOMBIC DODECAHEDRON
CUBE	$\frac{1}{2}\sqrt{2}$	$1+\sqrt{2}$	24-faced star DELTAHEDRON
DODECAHEDRON	$\frac{1}{19}\sqrt{\frac{1}{5}(65+22\sqrt{5})}$	$\frac{3}{19}(10-\sqrt{5})$	PENTAKIS DODECAHEDRON
DODECAHEDRON	$\sqrt{\frac{1}{10}(5-\sqrt{5})}$	$2\sqrt{5}-3$	60-faced star DELTAHEDRON
DODECAHEDRON	$\sqrt{\frac{1}{5}(5+2\sqrt{5})}$	$\sqrt{5}$	SMALL STELLATED DODECAHEDRON
ICOSAHEDRON	$\frac{1}{6}\sqrt{3}(\sqrt{5}-3)$	$3(\sqrt{5}-2)$	GREAT DODECAHEDRON
ICOSAHEDRON	$\frac{1}{15}\sqrt{15}$	$\frac{1}{5}(10-3\sqrt{5})$	SMALL TRIAMBIC ICOSAHEDRON
ICOSAHEDRON	$\frac{1}{3}\sqrt{6}$	$1-3\sqrt{2}+\sqrt{10}$	60-faced star DELTAHEDRON
ICOSAHEDRON	$\frac{1}{6}\sqrt{3}(3+\sqrt{5})$	3	GREAT STELLATED DODECAHEDRON
OCTAHEDRON	$\sqrt{3}-\frac{2}{3}\sqrt{6}$	$5-3\sqrt{2}$	SMALL TRIAKIS OCTAHEDRON
OCTAHEDRON	$\frac{1}{3}\sqrt{6}$	3	STELLA OCTANGULA
TETRAHEDRON	$\frac{1}{15}\sqrt{6}$	$\frac{7}{5}$	TRIAKIS TETRAHEDRON
TETRAHEDRON	$\frac{1}{6}\sqrt{6}$	2	CUBE
TETRAHEDRON	$\frac{1}{3}\sqrt{6}$	3	9-faced star DELTAHEDRON

Another type of cumulation (which I call "midpoint cumulation") replaces each facial polygon with triangular polygons joining vertices with the neighboring edge midpoints, and then constructs a pyramid with base determined by the face's midpoints. Midpoint cumulation allow compounds of Archimedean solids and their duals to be easily constructed.

ARCHIMEDEAN SOLID	dual	face 1	face 2
CUBOCTAHEDRON	RHOMBIC DODECAHEDRON	$3:\frac{1}{4}\sqrt{6}$	$4:\frac{1}{2}\sqrt{2}$
ICOSIDODECAHEDRON	RHOMBIC TRIACONTAHEDRON	$3:\frac{1}{4}\sqrt{\frac{1}{5}(\sqrt{7-3\sqrt{5}})}$	$\frac{1}{4}\sqrt{\frac{1}{5}(5+2\sqrt{5})}$
SMALL RHOMBICUBOCTAHEDRON	DELTOIDAL ICOSITETRAHEDRON	$3:\frac{1}{42}\sqrt{3}(3-\sqrt{2})$	$4:\frac{1}{2}(\sqrt{2}-1)$
TRUNCATED CUBE	SMALL TRIAKIS OCTAHEDRON	$3:\frac{1}{6}\sqrt{3}(3-2\sqrt{2})$	$8:\frac{1}{2}(1+\sqrt{2})$

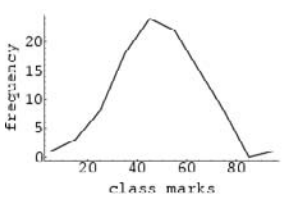
Cumulative Distribution Function

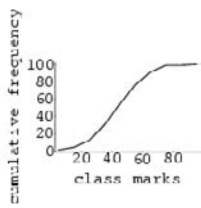
DISTRIBUTION FUNCTION

Cumulative Frequency

Let the ABSOLUTE FREQUENCIES of occurrence of an event in a number of CLASS INTERVALS be denoted f_1, f_2, ... The cumulative frequency corresponding to the upper boundary of any CLASS INTERVAL c_i in a FREQUENCY DISTRIBUTION is the total absolute frequency of all values less than that boundary, denoted



$$F_< \equiv \sum_{i\leq n} f_i.$$

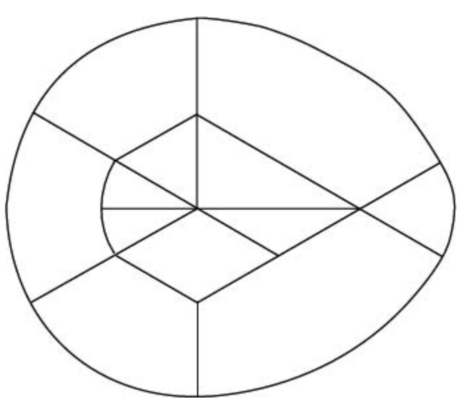


See also ABSOLUTE FREQUENCY, CLASS INTERVAL, CUMULATIVE FREQUENCY POLYGON, FREQUENCY DISTRIBUTION, RELATIVE CUMULATIVE FREQUENCY, RE-

LATIVE FREQUENCY

References
Kenney, J. F. and Keeping, E. S. "Cumulative Frequencies." §1.11 in *Mathematics of Statistics, Pt. 1, 3rd ed.* Princeton, NJ: Van Nostrand, pp. 17–9, 1962.

Cumulative Frequency Polygon



A plot of the cumulative frequency against the upper class boundary with the points joined by line segments. Any continuous cumulative frequency curve, including a cumulative frequency polygon, is called an OGIVE.

See also ABSOLUTE FREQUENCY, CLASS INTERVAL, FREQUENCY DISTRIBUTION, FREQUENCY POLYGON, OGIVE, RELATIVE CUMULATIVE FREQUENCY, RELATIVE FREQUENCY

Cunningham Chain

A SEQUENCE of PRIMES $q_1 < q_2 < \ldots < q_k$ is a Cunningham chain of the first kind (second kind) of length k if $q_{1+1} = 2q_i + 1$ ($q_{1+1} = 2q_i - 1$) for $i = 1, \ldots, k-1$. Cunningham PRIMES of the first kind are SOPHIE GERMAIN PRIMES.

The two largest known Cunningham chains (of the first kind) of length three are ($384205437 \cdot 2^{4000} - 1$, $384205437 \cdot 2^{4001} - 1$, $384205437 \cdot 2^{4002} - 1$) and ($651358155 \cdot 2^{3291} - 1$, $651358155 \cdot 2^{3292} - 1$, $651358155 \cdot 2^{3293} - 1$), both discovered by W. Roonguthai in 1998.

Cunningham Function

Sometimes also called the PEARSON-CUNNINGHAM FUNCTION. It can be expressed using WHITTAKER FUNCTIONS (Whittaker and Watson 1990, p. 353).

$$\omega_{n,m}(x) \equiv \frac{e^{\pi i(m/2-n)+x}}{\Gamma(1+n-\frac{1}{2}m)} U(\tfrac{1}{2}m - n,\ 1+m,\ x),$$

where $U(a, b, z)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND (Abramowitz and Stegun 1972, p. 510).

See also CONFLUENT HYPERGEOMETRIC FUNCTION OF THE SECOND KIND, WHITTAKER FUNCTION

Cunningham Number

A BINOMIAL NUMBER OF THE FORM $C^{\pm}(b, n) \equiv b^n \pm 1$. Bases b^k which are themselves powers need not be considered since they correspond to $(b^k)^n \pm 1 = b^{kn} \pm 1$. PRIME NUMBERS OF THE FORM $C^{\pm}(b, n)$ are very rare.

A NECESSARY (but not SUFFICIENT) condition for $C^{+}(2, n) = 2^n + 1$ to be PRIME is that n be OF THE FORM $n = 2^m$. Numbers OF THE FORM $F_m =$

$C^+(2, 2^m) = 2^{2^m} + 1$ are called FERMAT NUMBERS, and the only known PRIMES occur for $C^+(2, 1) = 3$, $C^+(2, 2) = 5$, $C^+(2, 4) = 17$, $C^+(2, 8) = 257$, and $C^+(2, 16) = 65537$ (i.e., $n = 0, 1, 2, 3, 4$). The only other PRIMES $C^+(b, n)$ for nontrivial $b \leq 11$ and $2 \leq n \leq 1000$ are $C^+(6, 2) = 37$, $C^+(6, 4) = 1297$, and $C^+(10, 2) = 101$.

PRIMES OF THE FORM $C^-(b, n)$ are also very rare. The MERSENNE NUMBERS $M_n = C^-(2, n) = 2^n - 1$ are known to be prime only for 37 values, the first few of which are $n = 2, 3, 5, 7, 13, 17, 19, ...$ (Sloane's A000043). There are no other PRIMES $C^-(b, n)$ for nontrivial $b \leq 20$ and $2 \leq n \leq 1000$.

In 1925, Cunningham and Woodall (1925) gathered together all that was known about the PRIMALITY and factorization of the numbers $C^{\pm}(b, n)$ and published a small book of tables. These tables collected from scattered sources the known prime factors for the bases 2 and 10 and also presented the authors' results of 30 years' work with these and other bases.

Since 1925, many people have worked on filling in these tables. D. H. Lehmer, a well-known mathematician who died in 1991, was for many years a leader of these efforts. Lehmer was a mathematician who was at the forefront of computing as modern electronic computers became a reality. He was also known as the inventor of some ingenious pre-electronic computing devices specifically designed for factoring numbers.

Updated factorizations were published in Brillhart *et al.* (1988). The current archive of Cunningham number factorizations for $b = 1, ..., \pm 12$ is kept on ftp://sable.ox.ac.uk/pub/math/cunningham/. The tables have been extended by Brent and te Riele (1992) to $b = 13, ..., 100$ with $m < 255$ for $b < 30$ and $m < 100$ for $b \geq 30$. All numbers with exponent 58 and smaller, and all composites with ≤ 90 digits have now been factored.

Cunningham Project

CUNNINGHAM NUMBER

Cup

See also CAP, CUP PRODUCT

References

Feller, W. *An Introduction to Probability Theory and Its Applications, Vol. 2, 3rd ed.* New York: Wiley, 1971.

Cup Product

The cup product is a product on COHOMOLOGY CLASSES. In the case of DE RHAM COHOMOLOGY, a COHOMOLOGY CLASS can be represented by a CLOSED FORM. The cup product of $[\alpha]$ and $[\beta]$ is represented by the CLOSED FORM $[\alpha \wedge \beta]$, where $\wedge$ is the WEDGE PRODUCT of DIFFERENTIAL K-FORMS. It is the dual operation to intersection in HOMOLOGY.

In general, the cup product is a map

$$\vee : H^p \times H^q \to H^{p+q}$$

which satisfies $a \vee b = (-1)^{pq} b \vee a$.

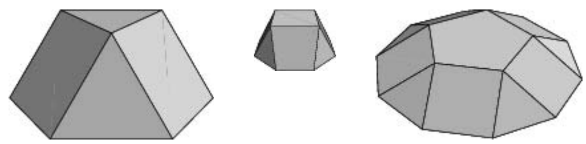
Cupola

An n-gonal cupola Q_n is a POLYHEDRON having n obliquely oriented TRIANGULAR and n rectangular faces separating an $\{n\}$ and a $\{2n\}$ REGULAR POLYGON, each oriented horizontally. The coordinates of the base VERTICES are

$$\left(R\cos\left[\frac{\pi(2k+1)}{2n}\right],\ R\sin\left[\frac{\pi(2k+1)}{2n}\right],\ 0\right), \tag{1}$$

and the coordinates of the top VERTICES are



$$\left(r\cos\left[\frac{2k\pi}{n}\right],\ r\sin\left[\frac{2k\pi}{n}\right],\ z\right), \tag{2}$$

where R and r are the CIRCUMRADII of the base and top

$$R = \tfrac{1}{2} a \csc\left(\frac{\pi}{2n}\right) \tag{3}$$

$$r = \tfrac{1}{2} a \csc\left(\frac{\pi}{n}\right), \tag{4}$$

and z is the height.

A cupola with all unit edge lengths (in which case the triangles become unit equilateral triangles and the rectangles become unit squares) is possible only for $n = 3, 4, 5$, in which case the height z can be obtained by letting $k = 0$ in the equations (1) and (2) to obtain the coordinates of neighboring bottom and top VERTICES,

$$\mathbf{b} = \begin{bmatrix} R \cos\left(\frac{\pi}{2n}\right) \\ R \sin\left(\frac{\pi}{2n}\right) \\ 0 \end{bmatrix} \tag{5}$$

$$\mathbf{t} = \begin{bmatrix} r \\ 0 \\ z \end{bmatrix}. \tag{6}$$

Since all side lengths are a,

$$|\mathbf{b} - \mathbf{t}|^2 = a^2. \tag{7}$$

Solving for z then gives

$$\left[R \cos\left(\frac{\pi}{2n}\right) - r\right]^2 + R^2 \sin^2\left(\frac{\pi}{2n}\right) + z^2 = a^2 \tag{8}$$

$$z^2 + R^2 + r^2 - 2rR \cos\left(\frac{\pi}{2n}\right) = a^2 \tag{9}$$

$$z = \sqrt{a^2 - 2rR \cos\left(\frac{\pi}{2n}\right) - r^2 - R^2}$$
$$= a\sqrt{1 - \tfrac{1}{4} \csc^2\left(\frac{\pi}{n}\right)} \tag{10}$$

Curl

The curl of a TENSOR field is given by

$$(\nabla \times A)^\alpha = \epsilon^{\alpha\mu\nu} A_{\nu;\mu}, \tag{1}$$

where ϵ_{ijk} is the LEVI-CIVITA TENSOR and ";" is the COVARIANT DERIVATIVE. For a VECTOR FIELD, the curl is denoted

$$\operatorname{curl}(\mathbf{F}) \equiv \nabla \times \mathbf{F}, \tag{2}$$

and $\nabla \times \mathbf{F}$ is normal to the PLANE in which the "circulation" is MAXIMUM. Its magnitude is the limiting value of circulation per unit AREA,

$$(\nabla \times \mathbf{F}) \cdot \hat{\mathbf{n}} \equiv \lim_{A \to 0} \frac{\oint_C \mathbf{F} \cdot d\mathbf{s}}{A}. \tag{3}$$

Let

$$\mathbf{F} \equiv F_1 \hat{\mathbf{u}}_1 + F_2 \hat{\mathbf{u}}_2 + F_3 \hat{\mathbf{u}}_3 \tag{4}$$

and

$$h_i \equiv \left|\frac{\partial \mathbf{r}}{\partial u_i}\right|, \tag{5}$$

then

$$\nabla \times \mathbf{F} \equiv \frac{1}{h_1 h_2 h_3} \begin{vmatrix} h_1 \hat{\mathbf{u}}_1 & h_2 \hat{\mathbf{u}}_2 & h_3 \hat{\mathbf{u}}_3 \\ \frac{\partial}{\partial u_1} & \frac{\partial}{\partial u_2} & \frac{\partial}{\partial u_3} \\ h_1 F_1 & h_2 F_2 & h_2 F_2 \end{vmatrix}$$
$$= \frac{1}{h_2 h_3}\left[\frac{\partial}{\partial u_2}(h_3 F_3) - \frac{\partial}{\partial u_3}(h_2 F_2)\right]\hat{\mathbf{u}}_1$$
$$+ \frac{1}{h_1 h_3}\left[\frac{\partial}{\partial u_3}(h_1 F_1) - \frac{\partial}{\partial u_1}(h_3 F_3)\right]\hat{\mathbf{u}}_2$$
$$+ \frac{1}{h_1 h_2}\left[\frac{\partial}{\partial u_1}(h_2 F_2) - \frac{\partial}{\partial u_2}(h_1 F_1)\right]\hat{\mathbf{u}}_3. \tag{6}$$

Special cases of the curl formulas above can be given for CURVILINEAR COORDINATES.

Curl Theorem

A special case of STOKES' THEOREM in which F is a VECTOR FIELD and M is an oriented, compact embedded 2-MANIFOLD with boundary in $\mathbb{R}^2$, given by

$$\int_S (\nabla \times \mathbf{F}) \cdot d\mathbf{a} = \int_{\partial S} \mathrm{F} \cdot d\mathbf{s}. \tag{1}$$

There are also alternate forms. If

$$\mathbf{F} \equiv \mathbf{c}F, \tag{2}$$

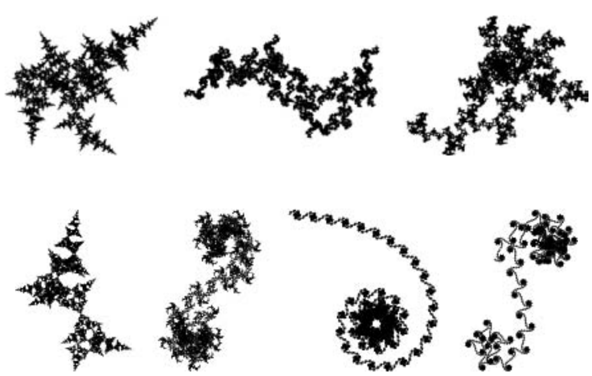
then

$$\int_S d\mathbf{a} \times \nabla F = \int_C F \, d\mathbf{s}. \tag{3}$$

and if

$$\mathbf{F} \equiv \mathbf{c} \times \mathbf{P}, \tag{4}$$

then



$$\int_S (d\mathbf{a} \times \nabla) \times \mathbf{P} = \int_C d\mathbf{s} \times \mathbf{P}. \tag{5}$$

Curlicue Fractal

The curlicue fractal is a figure obtained by the following procedure. Let s be an IRRATIONAL NUMBER. Begin with a line segment of unit length, which makes an ANGLE $\phi_0 \equiv 0$ to the horizontal. Then define θ_n iteratively by

$$\theta_{n+1} = (\theta_n + 2\pi s)(\text{mod } 2\pi),$$

with $\theta_0 = 0$. To the end of the previous line segment, draw a line segment of unit length which makes an angle

$$\phi_{n+1} = \theta_n + \phi_n (\text{mod } 2\pi),$$

to the horizontal (Pickover 1995). The result is a FRACTAL, and the above figures correspond to the curlicue fractals with 10,000 points for the GOLDEN RATIO ϕ, $\ln 2$, e, $\sqrt{2}$, the EULER-MASCHERONI CONSTANT γ, π, and FEIGENBAUM CONSTANT δ.

The TEMPERATURE of these curves is given in the following table.

Constant	Temperature
GOLDEN RATIO ϕ	46
$\ln 2$	51
e	58
$\sqrt{2}$	58
EULER-MASCHERONI CONSTANT γ	63
π	90
FEIGENBAUM CONSTANT α	92

ABLE CURRENT

Curtate Cycloid

The path traced out by a fixed point at a RADIUS $b < a$, where a is the RADIUS of a rolling CIRCLE, sometimes also called a CONTRACTED CYCLOID.

$$x = a\phi - b \sin \phi \qquad (1)$$

$$y = a - b \cos \phi. \qquad (2)$$

The ARC LENGTH from $\phi = 0$ is

$$s = 2(a + b)E(u), \qquad (3)$$

where

$$\sin(\tfrac{1}{2}\phi) = \operatorname{sn} u \qquad (4)$$

$$k^2 = \frac{4ab}{(a + c)^2}, \qquad (5)$$

and $E(u)$ is a complete ELLIPTIC INTEGRAL OF THE SECOND KIND and $\operatorname{sn} u$ is a JACOBI ELLIPTIC FUNCTION.

Curtate Cycloid Evolute

The EVOLUTE of the CURTATE CYCLOID

$$x = a\phi - b \sin \phi \qquad (1)$$

$$y = a - b \cos \phi. \qquad (2)$$

is given by

$$x = \frac{a[-2b\phi + 2a\phi \cos \phi - 2a \sin \phi + b \sin(2\phi)]}{2(a \cos \phi - b)} \qquad (3)$$

$$y = \frac{a(a - b \cos \phi)^2}{b(a \cos \phi - b)}. \qquad (4)$$

Curvature

In general, there are two important types of curvature: EXTRINSIC CURVATURE and INTRINSIC CURVATURE. The EXTRINSIC CURVATURE of curves in 2- and 3-space was the first type of curvature to be studied historically, culminating in the FRENET FORMULAS, which describe a SPACE CURVE entirely in terms of its "curvature," TORSION, and the initial starting point and direction.

After the curvature of 2- and 3-d curves was studied, attention turned to the curvature of surfaces in 3-space. The main curvatures which emerged from this scrutiny are the MEAN CURVATURE, GAUSSIAN CURVATURE, and the WEINGARTEN MAP. MEAN CURVATURE was the most important for applications at the time and was the most studied, but Gauss was the first to recognize the importance of the GAUSSIAN CURVATURE.

Because GAUSSIAN CURVATURE is "intrinsic," it is detectable to 2-dimensional "inhabitants" of the surface, whereas MEAN CURVATURE and the WEINGARTEN MAP are not detectable to someone who can't study the 3-dimensional space surrounding the surface on which he resides. The importance of GAUSSIAN CURVATURE to an inhabitant is that it controls the surface AREA of SPHERES around the inhabitant.

Riemann and many others generalized the concept of curvature to SECTIONAL CURVATURE, SCALAR CURVATURE, the RIEMANN TENSOR, RICCI CURVATURE, and a host of other INTRINSIC and EXTRINSIC CURVATURES. General curvatures no longer need to be numbers, and can take the form of a MAP, GROUP, GROUPOID, tensor field, etc.

The simplest form of curvature and that usually first encountered in CALCULUS is an EXTRINSIC CURVATURE. In 2-D, let a PLANE CURVE be given by CARTESIAN PARAMETRIC EQUATIONS $x = x(t)$ and $y = y(t)$. Then the curvature κ is defined by

$$\kappa \equiv \frac{d\phi}{ds} = \frac{\frac{d\phi}{dt}}{\frac{ds}{dt}} = \frac{\frac{d\phi}{dt}}{\sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}} = \frac{\frac{d\phi}{dt}}{\sqrt{x'^2 + y'^2}}, \qquad (1)$$

where ϕ is the TANGENTIAL ANGLE and s is the ARC LENGTH. As can readily be seen from the definition, curvature therefore has units of inverse distance. The $\frac{d\phi}{dt}$ derivative in the above equation can be found using the identity

$$\tan \phi = \frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{y'}{x'}, \qquad (2)$$

so

$$\frac{d}{dt}(\tan \phi) = \sec^2 \phi \frac{d\phi}{dt} = \frac{x'y'' - y'x''}{x'^2} \qquad (3)$$

and

$$\frac{d\phi}{dt} = \frac{1}{\sec^2\phi}\frac{d}{dt}(\tan\phi) = \frac{1}{1+\tan^2\phi}\frac{x'y''-y'x''}{x'^2}$$
$$= \frac{1}{1+\frac{y'^2}{x'^2}}\frac{x'y''-y'x''}{x'^2} = \frac{x'y''-y'x''}{x'^2+y'^2}. \tag{4}$$

Combining (1), (2), and (4) then gives

$$\kappa = \frac{x'y''-y'x''}{(x'^2+y'^2)^{3/2}}. \tag{5}$$

For a 2-D curve written in the form $y=f(x)$, the equation of curvature becomes

$$\kappa = \frac{\frac{d^2y}{dx^2}}{\left[1+\left(\frac{dy}{dx}\right)^2\right]^{3/2}}. \tag{6}$$

If the 2-D curve is instead parameterized in POLAR COORDINATES, then

$$\kappa = \frac{r^2+2r_\theta^2-rr_{\theta\theta}}{(r^2+r_\theta^2)^{3/2}}, \tag{7}$$

where $r_\theta \equiv \partial r/\partial\theta$ (Gray 1997, p. 89). In PEDAL COORDINATES, the curvature is given by

$$\kappa = \frac{1}{r}\frac{dp}{dr}. \tag{8}$$

The curvature for a 2-D curve given implicitly by $g(x, y)=0$ is given by

$$\kappa = \frac{g_{xx}g_y^2 - 2g_{xy}g_xg_y + g_{yy}g_x^2}{(g_x^2+g_y^2)^{3/2}} \tag{9}$$

(Gray 1997).

Now consider a parameterized SPACE CURVE $\mathbf{r}(t)$ in 3-D for which the TANGENT VECTOR $\hat{\mathbf{T}}$ is defined as

$$\hat{\mathbf{T}} \equiv \frac{\frac{d\mathbf{r}}{dt}}{\left|\frac{d\mathbf{r}}{dt}\right|} = \frac{\frac{d\mathbf{r}}{dt}}{\frac{ds}{dt}}. \tag{10}$$

Therefore,

$$\frac{d\mathbf{r}}{dt} = \frac{ds}{dt}\hat{\mathbf{T}} \tag{11}$$

$$\frac{d^2\mathbf{r}}{dt^2} = \frac{d^2s}{dt^2}\hat{\mathbf{T}} + \frac{ds}{dt}\frac{d\hat{\mathbf{T}}}{dt} = \frac{ds^2}{dt^2}\hat{\mathbf{T}} + \kappa\hat{\mathbf{N}}\left(\frac{ds}{dt}\right)^2, \tag{12}$$

where $\hat{\mathbf{N}}$ is the NORMAL VECTOR. But

$$\frac{d\mathbf{r}}{dt}\times\frac{d^2\mathbf{r}}{dt^2} = \frac{ds}{dt}\frac{d^2s}{dt^2}(\hat{\mathbf{T}}\times\hat{\mathbf{T}}) + \kappa\left(\frac{ds}{dt}\right)^3(\hat{\mathbf{T}}\times\hat{\mathbf{N}})$$

$$= \kappa\left(\frac{ds}{dt}\right)^3(\hat{\mathbf{T}}\times\hat{\mathbf{N}}) \tag{13}$$

$$\left|\frac{d\mathbf{r}}{dt}\times\frac{d^2\mathbf{r}}{dt^2}\right| = \kappa\left(\frac{ds}{dt}\right)^3 = \kappa\left|\frac{d\mathbf{r}}{dt}\right|^3, \tag{14}$$

so

$$\kappa = \left|\frac{d\hat{\mathbf{T}}}{ds}\right| = \frac{\left|\frac{d\mathbf{r}}{dt}\times\frac{d^2\mathbf{r}}{dt^2}\right|}{\left|\frac{d\mathbf{r}}{dt}\right|^3}. \tag{15}$$

The curvature of a 2-D curve is related to the RADIUS OF CURVATURE of the curve's OSCULATING CIRCLE. Consider a CIRCLE specified parametrically by

$$x = a\cos t \tag{16}$$

$$y = a\sin t \tag{17}$$

which is tangent to the curve at a given point. The curvature is then

$$\kappa = \frac{x'y''-y'x''}{(x'^2+y'^2)^{3/2}} = \frac{a^2}{a^3} = \frac{1}{a}, \tag{18}$$

or one over the RADIUS OF CURVATURE. The curvature of a CIRCLE can also be repeated in vector notation. For the CIRCLE with $0 \le t < 2\pi$, the ARC LENGTH is

$$s(t) = \int_0^t \sqrt{\left(\frac{dx}{dt}\right)^2+\left(\frac{dy}{dt}\right)^2}\,dt$$
$$= \int_0^t \sqrt{a^2\cos^2 t + a^2\sin^2 t}\,dt = at, \tag{19}$$

so $t=s/a$ and the equations of the CIRCLE can be rewritten as

$$x = a\cos\left(\frac{s}{a}\right) \tag{20}$$

$$y = a\sin\left(\frac{s}{a}\right). \tag{21}$$

The POSITION VECTOR is then given by

$$\mathbf{r}(s) = a\cos\left(\frac{s}{a}\right)\hat{\mathbf{x}} + a\sin\left(\frac{s}{a}\right)\hat{\mathbf{y}}, \tag{22}$$

and the TANGENT VECTOR is

$$\hat{\mathbf{T}} = \frac{d\mathbf{r}}{ds} = -\sin\left(\frac{s}{a}\right)\hat{\mathbf{x}} + \cos\left(\frac{s}{a}\right)\hat{\mathbf{y}}, \tag{23}$$

so the curvature is related to the RADIUS OF CURVATURE a by

$$\kappa = \left|\frac{d\hat{\mathbf{T}}}{ds}\right| = \left|-\frac{1}{a}\cos\left(\frac{s}{a}\right)\hat{\mathbf{x}} - \frac{1}{a}\sin\left(\frac{s}{a}\right)\hat{\mathbf{y}}\right|$$

$$= \sqrt{\frac{\cos^2\left(\frac{s}{a}\right) + \sin^2\left(\frac{s}{a}\right)}{a^2}} = \frac{1}{a}, \quad (24)$$

as expected.

Four very important derivative relations in differential geometry related to the FRENET FORMULAS are

$$\dot{\mathbf{r}} = \mathbf{T} \quad (25)$$

$$\ddot{\mathbf{r}} = \kappa \mathbf{N} \quad (26)$$

$$\dddot{\mathbf{r}} = \dot{\kappa}\mathbf{N} + \kappa(\tau\mathbf{B} - \kappa\mathbf{T}) \quad (27)$$

$$[\dot{\mathbf{r}}, \ddot{\mathbf{r}}, \dddot{\mathbf{r}}] = \kappa^2\tau, \quad (28)$$

where $\mathbf{T}$ is the TANGENT VECTOR, $\mathbf{N}$ is the NORMAL VECTOR, $\mathbf{B}$ is the BINORMAL VECTOR, and τ is the TORSION (Coxeter 1969, p. 322).

The curvature at a point on a surface takes on a variety of values as the PLANE through the normal varies. As κ varies, it achieves a minimum and a maximum (which are in perpendicular directions) known as the PRINCIPAL CURVATURES. As shown in Coxeter (1969, pp. 352–53),

$$\kappa^2 - \sum b_i^i \kappa + \det(b_i^j) = 0 \quad (29)$$

$$\kappa^2 - 2H\kappa + K = 0, \quad (30)$$

where K is the GAUSSIAN CURVATURE, H is the MEAN CURVATURE, and det denotes the DETERMINANT.

The curvature κ is sometimes called the FIRST CURVATURE and the TORSION τ the SECOND CURVATURE. In addition, a THIRD CURVATURE (sometimes called TOTAL CURVATURE)

$$\sqrt{ds_T^2 + ds_B^2} \quad (31)$$

is also defined. A signed version of the curvature of a CIRCLE appearing in the DESCARTES CIRCLE THEOREM for the radius of the fourth of four mutually tangent circles is called the BEND.

Curvature Center

The point on the POSITIVE RAY of the NORMAL VECTOR at a distance $\rho(s)$, where ρ is the RADIUS OF CURVATURE. It is given by

$$\mathbf{z} = \mathbf{x} + \rho\mathbf{N} = \mathbf{x} + \rho^2 \frac{\mathbf{T}}{ds}, \quad (1)$$

where $\mathbf{N}$ is the NORMAL VECTOR and $\mathbf{T}$ is the TANGENT VECTOR. It can be written in terms of $\mathbf{x}$ explicitly as

$$\mathbf{z} = \mathbf{x} + \frac{\mathbf{x}''(\mathbf{x}' \cdot \mathbf{x}')^2 - \mathbf{x}'(\mathbf{x}' \cdot \mathbf{x}')(\mathbf{x}' \cdot \mathbf{x}'')}{(\mathbf{x}' \cdot \mathbf{x}')(\mathbf{x}'' \cdot \mathbf{x}'') - (\mathbf{x}' \cdot \mathbf{x}'')^2}. \quad (2)$$

For a CURVE represented parametrically by $(f(t), g(t))$,

$$\alpha = f - \frac{(f'^2 - g'^2)g'}{f'g'' - f''g'} \quad (3)$$

$$\beta = g + \frac{(f'^2 - g'^2)f'}{f'g'' - f''g'} \quad (4)$$

Curvature Scalar

SCALAR CURVATURE

Curvature Vector

$$\mathbf{K} \equiv \frac{d\mathbf{T}}{ds},$$

where **T** is the TANGENT VECTOR defined by

$$\mathbf{T} \equiv \frac{\frac{d\mathbf{x}}{ds}}{\left|\frac{d\mathbf{x}}{ds}\right|}.$$

Curve

A CONTINUOUS MAP from a 1-D SPACE to an n-D SPACE. Loosely speaking, the word "curve" is often used to mean the GRAPH of a 2- or 3-D curve. The simplest curves can be represented parametrically in n-D SPACE as

$$x_1 = f_1(t)$$
$$x_2 = f_2(t)$$
$$\vdots$$
$$x_n = f_n(t).$$

Other simple curves can be simply defined only implicitly, i.e., in the form

$$f(x_1, x_2, \ldots) = 0.$$

Curve of Constant Breadth

CURVE OF CONSTANT WIDTH

Curve of Constant Precession

A curve whose CENTRODE revolves about a fixed axis with constant ANGLE and SPEED when the curve is traversed with unit SPEED. The TANGENT INDICATRIX of a curve of constant precession is a SPHERICAL HELIX. An ARC LENGTH parameterization of a curve of constant precession with NATURAL EQUATIONS

$$\kappa(s) = -\omega \sin(\mu s) \quad (1)$$

$$\tau(s) = -\omega \cos(\mu s) \quad (2)$$

is

$$x(s) = \frac{\alpha+\mu}{2\alpha}\frac{\sin[(\alpha-\mu)s]}{\alpha-\mu} - \frac{\alpha-\mu}{2\alpha}\frac{\sin[(\alpha+\mu)s]}{\alpha+\mu} \quad (3)$$

$$y(s) = \frac{\alpha+\mu}{2\alpha}\frac{\sin[(\alpha-\mu)s]}{\alpha-\mu} + \frac{\alpha-\mu}{2\alpha}\frac{\cos[(\alpha+\mu)s]}{\alpha+\mu} \quad (4)$$

$$z(s) = \frac{\omega}{\mu\alpha}\sin(\mu s), \quad (5)$$

where

$$\alpha \equiv \sqrt{\omega^2+\mu^2} \quad (6)$$

and ω, and μ are constant. This curve lies on a circular one-sheeted HYPERBOLOID

$$x^2 + y^2 - \frac{\mu^2}{\omega^2} z^2 = \frac{4\mu^2}{\omega^4}. \quad (7)$$

The curve is closed IFF μ/α is RATIONAL.

Curve of Constant Slope

GENERALIZED HELIX

Curve of Constant Width

Curves which, when rotated in a square, make contact with all four sides. Such curves are sometimes also known as ROLLERS.

The "width" of a closed convex curve is defined as the distance between parallel lines bounding it ("supporting lines"). Every curve of constant width is convex. Curves of constant width have the same "width" regardless of their orientation between the parallel lines. In fact, they also share the same PERIMETER (BARBIER'S THEOREM). Examples include the CIRCLE (with largest AREA), and REULEAUX TRIANGLE (with smallest AREA) but there are an infinite number. A curve of constant width can be used in a special drill chuck to cut square "HOLES."

A generalization gives solids of constant width. These do not have the same surface AREA for a given width,

but their shadows are curves of constant width with the *same* width!

Curvilinear Coordinates

A COORDINATE SYSTEM composed of intersecting surfaces. If the intersections are all at right angles, then the curvilinear coordinates are said to form an ORTHOGONAL COORDINATE SYSTEM. If not, they form a SKEW COORDINATE SYSTEM.

A general METRIC $g_{\mu\nu}$ has a LINE ELEMENT

$$ds^2 = g_{\mu\nu} du^\mu du^\nu, \tag{1}$$

where EINSTEIN SUMMATION is being used. Curvilinear coordinates are defined as those with a diagonal METRIC so that

$$g_{\mu\nu} \equiv \delta^\mu_\nu h^2_\mu, \tag{2}$$

where δ^μ_ν is the KRONECKER DELTA. Curvilinear coordinates therefore have a simple LINE ELEMENT

$$ds^2 = \delta^\mu_\nu h^2_\mu du^\mu du^\nu = h^2_\mu du^{\mu 2}, \tag{3}$$

which is just the PYTHAGOREAN THEOREM, so the differential VECTOR is

$$d\mathbf{r} = h_\mu \, du_\mu \, \hat{\mathbf{u}}_\mu, \tag{4}$$

or

$$d\mathbf{r} = \frac{\partial \mathbf{r}}{\partial u_1} du_1 + \frac{\partial \mathbf{r}}{\partial u_2} du_2 + \frac{\partial \mathbf{r}}{\partial u_3} du_3, \tag{5}$$

where the SCALE FACTORS are

$$h_i \equiv \left| \frac{\partial \mathbf{r}}{\partial u_i} \right| \tag{6}$$

and

$$\hat{\mathbf{u}}_i \equiv \frac{\frac{\partial \mathbf{r}}{\partial u_i}}{\left|\frac{\partial \mathbf{r}}{\partial u_i}\right|} = \frac{1}{h_i} \frac{\partial \mathbf{r}}{\partial u_i}. \tag{7}$$

Equation (5) may therefore be re-expressed as

$$d\mathbf{r} = h_1 \, du_1 \hat{\mathbf{u}}_1 + h_2 \, du_2 \hat{\mathbf{u}}_2 + h_3 \, du_3 \hat{\mathbf{u}}_3. \tag{8}$$

The GRADIENT is

$$\begin{aligned} \operatorname{grad}(\phi) &\equiv \nabla \phi \\ &= \frac{1}{h_1} \frac{\partial \phi}{\partial u_1} \hat{\mathbf{u}}_1 + \frac{1}{h_2} \frac{\partial \phi}{\partial u_2} \hat{\mathbf{u}}_2 + \frac{1}{h_3} \frac{\partial \phi}{\partial u_3} \hat{\mathbf{u}}_3, \end{aligned} \tag{9}$$

the DIVERGENCE is

$$\begin{aligned} \operatorname{div}(F) \equiv \nabla \cdot \mathbf{F} \equiv \frac{1}{h_1 h_2 h_3} \\ \times \left[\frac{\partial}{\partial u_1}(h_2 h_3 F_1) + \frac{\partial}{\partial u_2}(h_3 h_1 F_2) + \frac{\partial}{\partial u_3}(h_1 h_2 F_3) \right], \end{aligned} \tag{10}$$

and the CURL is

$$\begin{aligned} \nabla \times \mathbf{F} &\equiv \frac{1}{h_1 h_2 h_3} \begin{vmatrix} h_1 \hat{\mathbf{u}}_1 & h_2 \hat{\mathbf{u}}_2 & h_3 \hat{\mathbf{u}}_3 \\ \frac{\partial}{\partial u_1} & \frac{\partial}{\partial u_2} & \frac{\partial}{\partial u_3} \\ h_1 F_1 & h_2 F_2 & h_2 F_2 \end{vmatrix} \\ &= \frac{1}{h_2 h_3} \left[\frac{\partial}{\partial u_2}(h_3 F_3) - \frac{\partial}{\partial u_3}(h_2 F_2) \right] \hat{\mathbf{u}}_1 \\ &\quad + \frac{1}{h_1 h_3} \left[\frac{\partial}{\partial u_3}(h_1 F_1) - \frac{\partial}{\partial u_1}(h_3 F_3) \right] \hat{\mathbf{u}}_2 \\ &\quad + \frac{1}{h_1 h_2} \left[\frac{\partial}{\partial u_1}(h_2 F_2) - \frac{\partial}{\partial u_2}(h_1 F_1) \right] \hat{\mathbf{u}}_3. \end{aligned} \tag{11}$$

Walker, R. J. *Algebraic Curves.* New York: Springer-Verlag, pp. 57–8, 1978.

Cusp Catastrophe

A CATASTROPHE which can occur for two control factors and one behavior axis. The cusp catastrophe is the universal unfolding of the singularity $f(x) = x^4$ and has the equation $F(x, u, v) = x^4 + ux^2 + vx$. The equation $y = x^{2/3}$ also has a cusp catastrophe.

Cusp Form

A cusp form is a MODULAR FORM for which the coefficient $c(0) = 0$ in the FOURIER SERIES

$$f(\tau) = \sum_{n=0}^{\infty} c(n) e^{2\pi i n \tau}$$

(Apostol 1997, p. 114). The only entire cusp form of weight $k < 12$ is the zero function (Apostol 1997, p. 116). The set of all cusp forms in M_k (all MODULAR FORMS of weight k) is a linear subspace of M_k which is denoted $M_{k,0}$. The dimension of $M_{k,0}$ is 1 for $k = 12$, 16, 18, 20, 22, and 26 (Apostol 1997, p. 119). For a cusp form $f \in M_{2k,0}$,

$$c(n) = \mathcal{O}(n^k) \quad (1)$$

(Apostol 1997, p. 135) or, more precisely,

$$c(n) = \mathcal{O}(n^{k-1/4+\epsilon}) \quad (2)$$

for every $\epsilon > 0$ (Selberg 1965; Apostol 1997, p. 136). It is conjectured that the $-1/4$ in the exponent can be reduced to $-1/2$ (Apostol 1997, p. 136).

Cusp Point

CUSP

Cut

Given a weighted, UNDIRECTED GRAPH $G = (V,\ E)$ and a GRAPHICAL PARTITION of V into two sets A and B, the cut of G with respect to A and B is defined as

$$\text{cut}(A,\ B) = \sum_{i \in A,\ j \in B} W(i,\ j),$$

where $W(i,\ j)$ denotes the weight for the edge connecting vertices i and j.

ARTICULATION VERTEX

CW-Approximation Theorem

If X is any SPACE, then there is a CW-COMPLEX Y and a MAP $f : Y \to X$ inducing ISOMORPHISMS on all HOMOTOPY, HOMOLOGY, and COHOMOLOGY groups.

CW-Complex

A CW-complex is a homotopy-theoretic generalization of the notion of a SIMPLICIAL COMPLEX. A CW-complex is any SPACE X which can be built by starting off with a discrete collection of points called X^0, then attaching 1-D DISKS D^1 to X^0 along their boundaries $\mathbb{S}^0$, writing X^1 for the object obtained by attaching the $\mathbb{D}^1$ s to X^0, then attaching 2-D DISKS $\mathbb{D}^2$ to X^1 along their boundaries $\mathbb{S}^1$, writing X^2 for the new SPACE, and so on, giving spaces X^n for every n. A CW-complex is any SPACE that has this sort of decomposition into SUBSPACES X^n built up in such a hierarchical fashion (so the X^ns must exhaust all of X). In particular, X^n may be built from X^{n-1} by attaching infinitely many n-DISKS, and the attaching MAPS $\mathbb{S}^{n-1} \to X^{n-1}$ may be any continuous MAPS.

The main importance of CW-complexes is that, for the sake of HOMOTOPY, HOMOLOGY, and COHOMOLOGY groups, every SPACE is a CW-complex. This is called the CW-APPROXIMATION THEOREM. Another is WHITEHEAD'S THEOREM, which says that MAPS between CW-complexes that induce ISOMORPHISMS on all HOMOTOPY GROUPS are actually HOMOTOPY equivalences.

See also COHOMOLOGY, CW-APPROXIMATION THEOREM, HOMOLOGY GROUP, HOMOTOPY GROUP, SIMPLICIAL COMPLEX, SPACE, SUBSPACE, WHITEHEAD'S THEOREM

Cycle (Circle)

A CIRCLE with an arrow indicating a direction.

Cycle (Map)

An n-cycle is a finite sequence of points Y_0, ..., Y_{n-1} such that, under a MAP G,

$$Y_1 = G(Y_0)$$
$$Y_2 = G(Y_1)$$
$$Y_{n-1} = G(Y_{n-2})$$
$$Y_0 = G(Y_{n-1}).$$

In other words, it is a periodic trajectory which comes back to the same point after n iterations of the cycle. Every point Y_j of the cycle satisfies $Y_j = G^n(Y_j)$ and is therefore a FIXED POINT of the mapping G^n. A fixed point of G is simply a CYCLE of period 1.

Cycle (Permutation)

A SUBSET of a PERMUTATION whose elements trade places with one another. Permutations cycles are called "orbits" by Comtet (1974, p. 256). For example, in the PERMUTATION GROUP $\{4, 2, 1, 3\}$, $\{1, 3, 4\}$ is a 3-cycle ($1 \to 3$, $3 \to 4$, and $4 \to 1$) and $\{2\}$ is a 1-cycle ($2 \to 2$). There is a great deal of freedom in picking the representation of a cyclic decomposition since (1) the cycles are disjoint and can therefore be specified in any order, and (2) any rotation of a given cycle specifies the same cycle (Skiena 1990, p. 20). Therefore, (431)(2), (314)(2), (143)(2), (2)(431), (2)(314), and (2)(143) all describe the same cycle.

The cyclic decomposition of a PERMUTATION can be computed in *Mathematica* with the function `ToCycles[p]` in the *Mathematica* add-on package `DiscreteMath'Permutations'` (which can be loaded with the command `<<DiscreteMath'`) and the PERMUTATION corresponding to a cyclic decomposition can be computed with `FromCycles[c1, ..., cn]` in the *Mathematica* add-on package `DiscreteMath'Permutations'` (which can be loaded with the command `<<DiscreteMath'`). According to Vardi (1991), the *Mathematica* code for `ToCycles` is one of the most obscure ever written.

Every PERMUTATION GROUP on n symbols can be uniquely expressed as a product of disjoint cycles (Skiena 1990, p. 20). A cycle decomposition of a PERMUTATION can be viewed as a CLASS of a PERMUTATION GROUP.

The number $d_1(n, k)$ of k-cycles in a PERMUTATION GROUP of order n is given by

$$d_1(n, k) = (-1)^{n-k} S_1(n, k) = |S_1(n, k)|, \qquad (1)$$

where $S_1(n, m)$ are the STIRLING NUMBERS OF THE FIRST KIND. More generally, let $d_r(n, k)$ be the number of permutations of n having exactly k cycles all of which are of length $\geq r$. $d_2(n, k)$ are sometimes called the associated STIRLING NUMBERS OF THE FIRST KIND (Comtet 1974, p. 256). The quantities $d_3(n, k)$ appear in a closed-form expression for the coefficients of in STIRLING'S SERIES (Comtet 1974, p. 257 and 267). The following table gives the triangles for $d_r(n, k)$.

r	Sloane	$d_r(n, k)$
1	A008275	1; 1, 1; 2, 3, 1; 6, 11, 6, 1; 24, 50, 35, 10, 1; ...
2	A008306	1; 2; 6, 3; 24, 20; 120, 130, 15; 720, 924, 210; ...
3	A050211	2; 6; 24; 120, 40; 720, 420; 5040, 3948; 40320, ...
4	A050212	6; 24; 120; 720; 5040, 1260; 40320, 18144; ...
5	A050213	24; 120; 720; 5040; 40320; 362880, 72576; ...

The functions $d_r(n, k)$ are given by the RECURRENCE RELATION

$$d_r(n, k) = (n-1)d_r(n-1, k) + (n-1)_{r-1} d_r(n-r, k-1), \qquad (2)$$

where $(n)_k$ is the FALLING FACTORIAL, combined with the initial conditions

$$d_r(n, k) = 0 \quad \text{for } n \leq kr - 1 \qquad (3)$$

$$d_r(n, 1) = (n-1)! \qquad (4)$$

(Riordan 1958, p. 85; Comtet 1974, p. 257).

Cycle Decomposition

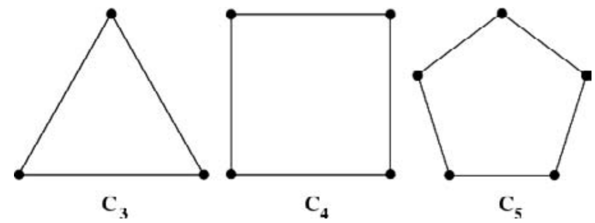
CYCLE (PERMUTATION)

Cycle Graph

A cycle graph C_n is a graph on n nodes containing a single cycle through all nodes. Cycle graphs can be generated using `Cycle[n]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`). The CHROMATIC NUMBER of C_n is given by

$$\chi(C_n) = \begin{cases} 3 & \text{for } n \text{ odd} \\ 2 & \text{for } n \text{ even.} \end{cases}$$

A cycle graph of a GROUP is a GRAPH which shows cycles of a GROUP as well as the connectivity between the cycles. Several examples are shown above. For $Z4$, the group elements A_i satisfy $A_i^4 = 1$, where 1 is the IDENTITY ELEMENT, and two elements satisfy $A_1^2 = A_3^2 = 1$.



For a CYCLIC GROUP of COMPOSITE ORDER n (e.g., $Z4$, $Z6$, $Z8$), the degenerate subcycles corresponding to factors dividing n are often not shown explicitly since their presence is implied.

Cyclic Graph

A GRAPH of n nodes and n edges such that node i is connected to the two adjacent nodes $i+1$ and $i-1$ (mod n), where the nodes are numbered 0, 1, ..., $n-1$.

Cyclic Group

A cyclic group $\mathbb{Z}_n$ (also commonly denoted Z_n or C_n; Shanks 1993, p. 75) of ORDER n is a GROUP defined by the element X (the GENERATOR) and its n POWERS up to

$$X^n = I,$$

where I is the IDENTITY ELEMENT. Cyclic groups are ABELIAN. There exists a unique cyclic group of every order $n \geq 2$, so cyclic groups of the same order are always isomorphic (Scott 1987, p. 34; Shanks 1993, p. 74). Furthermore, subgroups of cyclic groups are cyclic, and all GROUPS of PRIME ORDER are cyclic. In fact, the only SIMPLE ABELIAN GROUPS are the cyclic groups of order $n = 1$ or a n a prime (Scott 1987, p. 35).

Examples of cyclic groups include $\mathbb{Z}_2$, $\mathbb{Z}_3$, $\mathbb{Z}_4$, and the MODULO MULTIPLICATION GROUPS M_m such that $m = 2, 4, p^n$, or $2p^n$, for p an ODD PRIME and $n \geq 1$ (Shanks 1993, p. 92). By computing the CHARACTERISTIC FACTORS, any ABELIAN GROUP can be expressed as a GROUP DIRECT PRODUCT of cyclic SUBGROUPS, for example, $Z2 \otimes Z4$ or $Z2 \otimes Z2 \otimes Z2$.

Cyclic Hexagon

A hexagon (not necessarily regular) on whose VERTICES a CIRCLE may be CIRCUMSCRIBED. Let

$$\sigma_i \equiv \prod_i (a_1^2,\ a_2^2,\ a_3^2,\ a_4^2,\ a_5^2,\ a_6^2) \tag{1}$$

denote the ith-order SYMMETRIC POLYNOMIAL on the six variables consisting of the squares a_i^2 of the hexagon side lengths a_i, so

$$\sigma_1 = a_1^2 + a_2^2 + a_3^2 + a_4^2 + a_5^2 + a_6^2 \tag{2}$$

$$\begin{aligned}\sigma_2 = {} & a_1^2a_2^2 + a_1^2a_3^2 + a_1^2a_4^2 + a_1^2a_5^2 + a_1^2a_6^2 \\ & + a_2^2a_3^2 + a_2^2a_4^2 + a_2^2a_5^2 + a_2^2a_6^2 \\ & + a_3^2a_4^2 + a_3^2a_5^2 + a_3^2a_6^2 \\ & + a_4^2a_5^2 + a_4^2a_6^2 + a_5^2a_6^2\end{aligned} \tag{3}$$

$$\begin{aligned}\sigma_3 = {} & a_1^2a_2^2a_3^2 + a_1^2a_2^2a_4^2 + a_1^2a_2^2a_5^2 + a_1^2a_2^2a_6^2 \\ & + a_2^2a_3^2a_4^2 + a_2^2a_3^2a_5^2 + a_2^2a_3^2a_6^2 \\ & + a_3^2a_4^2a_5^2 + a_3^2a_4^2a_6^2 + a_4^2a_5^2a_6^2\end{aligned} \tag{4}$$

$$\begin{aligned}\sigma_4 = {} & a_1^2a_2^2a_3^2a_4^2 + a_1^2a_2^2a_3^2a_5^2 + a_1^2a_2^2a_3^2a_6^2 \\ & + a_1^2a_3^2a_4^2a_5^2 + a_1^2a_3^2a_4^2a_6^2 \\ & + a_1^2a_3^2a_5^2a_6^2 + a_1^2a_4^2a_5^2a_6^2 \\ & + a_2^2a_3^2a_4^2a_5^2 + a_2^2a_3^2a_4^2a_6^2 + a_2^2a_3^2a_5^2a_6^2 \\ & + a_2^2a_4^2a_5^2a_6^2 + a_3^2a_4^2a_5^2a_6^2\end{aligned} \tag{5}$$

$$\begin{aligned}\sigma_5 = {} & a_1^2a_2^2a_3^2a_4^2a_5^2 + a_1^2a_2^2a_3^2a_4^2a_6^2 \\ & + a_1^2a_2^2a_3^2a_5^2a_6^2 + a_1^2a_2^2a_4^2a_5^2a_6^2 \\ & + a_1^2a_3^2a_4^2a_5^2a_6^2 + a_2^2a_3^2a_4^2a_5^2a_6^2\end{aligned} \tag{6}$$

$$\sigma_6 = a_1^2a_2^2a_3^2a_4^2a_5^2a_6^2. \tag{7}$$

Then let K be the AREA of the hexagon and define

$$u = 16K^2 \tag{8}$$

$$t_2 = u - 4\sigma_2 + \sigma_1^2 \tag{9}$$

$$t_3 = 8\sigma_3 + \sigma_1 t_2 - 16\sqrt{\sigma_6} \tag{10}$$

$$t_4 = t_2^2 - 64\sigma_4 + 64\sigma_1\sqrt{\sigma_6} \tag{11}$$

$$t_5 = 128\sigma_5 + 32t_2\sqrt{\sigma_6}. \tag{12}$$

The AREA of the hexagon then satisfies

$$ut_4^3 + t_3^2t_4^2 - 16t_3^3t_5 - 18ut_3t_4t_5 - 27u^2t_5^2 = 0, \tag{13}$$

or this equation with $\sqrt{\sigma_6}$ replaced by $-\sqrt{\sigma_6}$, a seventh order POLYNOMIAL in u. This is $1/(4u^2)$ times the DISCRIMINANT of the CUBIC EQUATION

$$z^3 + 2t_3z^2 - ut_4z + 2u^2t_5. \tag{14}$$

Cyclic Number

A number having $n-1$ DIGITS which, when MULTIPLIED by 1, 2, 3, ..., $n-1$, produces the same digits in a different order. Cyclic numbers are generated by the UNIT FRACTIONS $1/n$ which have maximal period DECIMAL EXPANSIONS (which means n must be PRIME). The first few numbers which generate cyclic numbers are 7, 17, 19, 23, 29, 47, 59, 61, 97, ... (Sloane's A001913). A much larger generator is 17389.

It has been conjectured, but not yet proven, that an INFINITE number of cyclic numbers exist. In fact, the FRACTION of PRIMES which generate cyclic numbers seems to be approximately 3/8. See Yates (1973) for a table of PRIME period lengths for PRIMES $< 1,370,471$. When a cyclic number is multiplied by its generator, the result is a string of 9s. This is a special case of MIDY'S THEOREM.

Cyclic Pentagon

A cyclic pentagon is a not necessarily regular PENTAGON on whose VERTICES a CIRCLE may be CIRCUMSCRIBED. Let such a pentagon have edge lengths a_1, ..., a_5, and AREA K, and let

$$\sigma_i \equiv \Pi_i(a_1^2,\ a_2^2,\ a_3^2,\ a_4^2,\ a_5^2) \tag{1}$$

denote the ith-order SYMMETRIC POLYNOMIAL on the five variables consisting of the squares a_i^2 of the pentagon side lengths a_i, so

$$\sigma_1 = a_1^2 + a_2^2 + a_3^2 + a_4^2 + a_5^2 \tag{2}$$

$$\begin{aligned}\sigma_2 = {} & a_1^2a_2^2 + a_1^2a_3^2 + a_1^2a_4^2 + a_1^2a_5^2 + a_2^2a_3^2 \\ & + a_2^2a_4^2 + a_2^2a_5^2 + a_3^2a_4^2 + a_3^2a_5^2 \\ & + a_4^2a_5^2\end{aligned} \tag{3}$$

$$\begin{aligned}\sigma_3 = {} & a_1^2a_2^2a_3^2 + a_1^2a_2^2a_4^2 + a_1^2a_2^2a_5^2 \\ & + a_2^2a_3^2a_4^2 + a_2^2a_3^2a_5^2 + a_3^2a_4^2a_5^2\end{aligned} \tag{4}$$

$$\begin{aligned}\sigma_4 = {} & a_1^2a_2^2a_3^2a_4^2 + a_1^2a_2^2a_3^2a_5^2 + a_1^2a_3^2a_4^2a_5^2 \\ & + a_1^2a_2^2a_4^2a_5^2 + a_2^2a_3^2a_4^2a_5^2\end{aligned} \tag{5}$$

$$\sigma_5 = a_1^2a_2^2a_3^2a_4^2a_5^2. \tag{6}$$

In addition, also define

$$u = 16K^2 \tag{7}$$

$$t_2 = u - 4\sigma_2 + \sigma_1^2 \tag{8}$$

$$t_3 = 8\sigma_3 + \sigma_1 t_2 \tag{9}$$

$$t_4 = -64\sigma_4 + t_2^2 \tag{10}$$

$$t_5 = 128\sigma_5. \tag{11}$$

Then the AREA of the pentagon satisfies

$$ut_4^3 + t_3^2t_4^2 - 16t_3^3t_5 - 18ut_3t_4t_5 - 27u^2t_5^2 = 0, \tag{12}$$

a seventh order POLYNOMIAL in u (Robbins 1995). This is also $1/(4u^2)$ times the DISCRIMINANT of the CUBIC EQUATION

$$z^3 + 2t_3z^2 - ut_4z + 2u^2t_5 \tag{13}$$

(Robbins 1995).

Cyclic Permutation

A PERMUTATION which shifts all elements of a SET by a fixed offset, with the elements shifted off the end inserted back at the beginning. For a SET with elements a_0, a_1, ..., a_{n-1}, a cyclic permutation of one place to the left would yield a_1, ..., a_{n-1}, a_0, and a cyclic permutation of one place to the right would yield a_{n-1}, a_0, a_1, ...

The mapping can be written as $a_i \to a_{i+k \pmod n}$ for a shift of k places. A shift of k places to the left is implemented in *Mathematica* as `RotateLeft[`*list*`, `*k*`]`, while a shift of k places to the right is implemented as `RotateRight[`*list*`, `*k*`]`.

See also PERMUTATION

Cyclic Polygon

A cyclic polygon is a POLYGON with VERTICES upon which a CIRCLE can be CIRCUMSCRIBED. Since every TRIANGLE has a CIRCUMCIRCLE, every TRIANGLE is cyclic. It is conjectured that for a cyclic polygon of $2m+1$ sides, $16K^2$ (where K is the AREA) satisfies a MONIC POLYNOMIAL of degree Δ_m, where

$$\Delta_m = \sum_{k=0}^{m-1}(m-k)\binom{2m+1}{k} \tag{1}$$

$$= \frac{1}{2}\left[(2m+1)\binom{2m}{m} - 2^{2m}\right] \tag{2}$$

(Robbins 1995). It is also conjectured that a cyclic polygon with $2m+2$ sides satisfies one of two POLYNOMIALS of degree Δ_m. The first few values of Δ_m are 1, 7, 38, 187, 874, ... (Sloane's A000531).

For TRIANGLES $n = 3 = 2 \cdot 1 + 1$, the POLYNOMIAL is HERON'S FORMULA, which may be written

$$16K^2 = 2a^2b^2 + 2a^2c^2 + 2b^2c^2 - a^4 - b^4 - c^4, \tag{3}$$

and which is of order $\Delta_1 = 1$ in $16K^2$. For a CYCLIC QUADRILATERAL, the POLYNOMIAL is BRAHMAGUPTA'S FORMULA, which may be written

$$16K^2 = -a^4 + 2a^2b^2 - b^4 + 2a^2c^2 + 2b^2c^2 - c^4$$

$$+8abcd + 2a^2d^2 + 2b^2d^2 + 2c^2d^2 - d^4, \quad (4)$$

which is of order $\Delta_1 = 1$ in $16K^2$. Robbins (1995) gives the corresponding FORMULAS for the CYCLIC PENTAGON and CYCLIC HEXAGON.

Cyclic Quadrangle

Let A_1, A_2, A_3, and A_4 be four POINTS on a CIRCLE, and H_1, H_2, H_3, H_4 the ORTHOCENTERS of TRIANGLES $\Delta A_2A_3A_4$, etc. If, from the eight POINTS, four with different subscripts are chosen such that three are from one set and the fourth from the other, these POINTS form an ORTHOCENTRIC SYSTEM. There are eight such systems, which are analogous to the six sets of ORTHOCENTRIC SYSTEMS obtained using the feet of the ANGLE BISECTORS, ORTHOCENTER, and VERTICES of a generic TRIANGLE.

On the other hand, if all the POINTS are chosen from one set, or two from each set, with all different subscripts, the four POINTS lie on a CIRCLE. There are four pairs of such CIRCLES, and eight POINTS lie by fours on eight equal CIRCLES.

The SIMSON LINE of A_4 with regard to TRIANGLE $\Delta A_1A_2A_3$ is the same as that of H_4 with regard to the TRIANGLE $\Delta H_1A_2A_3$.

Cyclic Quadrilateral

A QUADRILATERAL for which a CIRCLE can be circumscribed so that it touches each VERTEX. The AREA is then given by a special case of BRETSCHNEIDER'S FORMULA. Let the sides have lengths a, b, c, and d, let s be the SEMIPERIMETER

$$s \equiv \tfrac{1}{2}(a+b+c+d), \quad (1)$$

and let R be the CIRCUMRADIUS. Then

$$A = \sqrt{(s-a)(s-b)(s-c)(s-d)} \quad (2)$$

$$= \frac{\sqrt{(ac+bd)(ad+bc)(ab+cd)}}{4R}. \quad (3)$$

Solving for the CIRCUMRADIUS gives

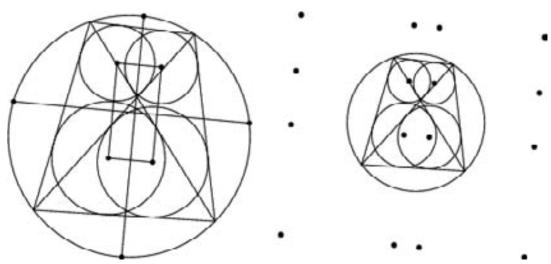
$$R = \tfrac{1}{4}\sqrt{\frac{(ac+bd)(ad+bc)(ab+cd)}{(s-a)(s-b)(s-c)(s-d)}}. \quad (4)$$

The DIAGONALS of a cyclic quadrilateral have lengths

$$p = \sqrt{\frac{(ab+cd)(ac+bd)}{ad+bc}} \quad (5)$$

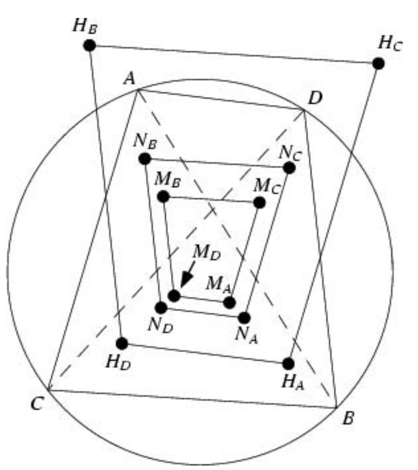
$$q = \sqrt{\frac{(ac+bd)(ad+bc)}{ab+cd}}, \quad (6)$$

so that $pq = ac + bd$.
In general, there are three essentially distinct cyclic quadrilaterals (modulo ROTATION and REFLECTION) whose edges are permutations of the lengths a, b, c, and d. Of the six corresponding DIAGONAL lengths, three are distinct. In addition to p and q, there is therefore a "third" DIAGONAL which can be denoted r. It is given by the equation



$$r = \sqrt{\frac{(ad+bc)(ab+cd)}{ac+bd}}. \quad (7)$$

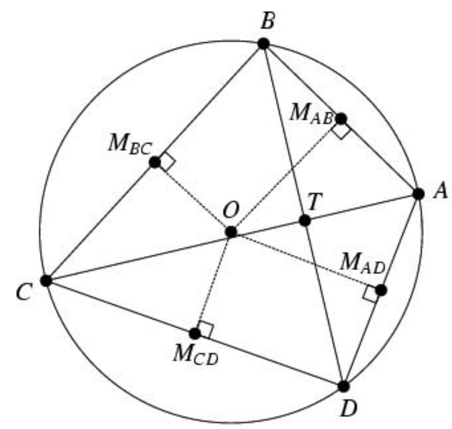
This allows the AREA formula to be written in the particularly beautiful and simple form



$$A = \frac{pqr}{4R}. \quad (8)$$

The DIAGONALS are sometimes also denoted p, q, and r.

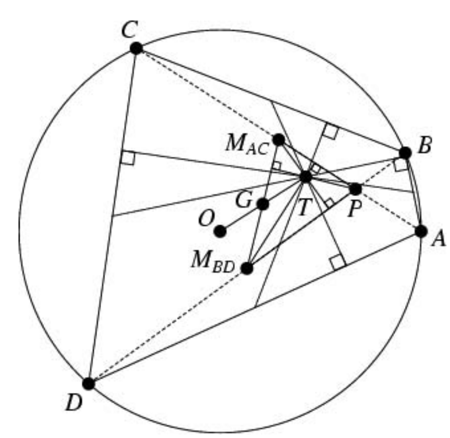
The AREA of a cyclic quadrilateral is the MAXIMUM possible for any QUADRILATERAL with the given side lengths. Also, the opposite ANGLES of a cyclic quadrilateral sum to π RADIANS (Dunham 1990). There exists a closed BILLIARDS path inside a cyclic quadrilateral if its CIRCUMCENTER lies inside the quadrilateral (Wells 1991, p. 11).



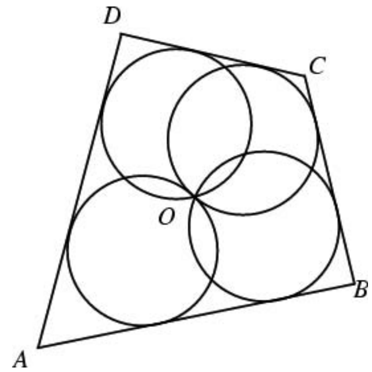
The INCENTERS of the four triangles composing the cyclic quadrilateral form a RECTANGLE. Furthermore, the sides of the RECTANGLE are PARALLEL to the lines connecting the MID-ARC POINTS between each pair of vertices (left figure above; Fuhrmann 1890, p. 50; Johnson 1929, pp. 254–55; Wells 1991). If the EXCENTERS of the triangles constituting the quadrilateral are added to the INCENTERS, a 4×4 rectangular grid is obtained (right figure; Johnson 1929, p. 255; Wells 1991).

Consider again the four triangles contained in a cyclic quadrilateral. Amazingly, the CENTROIDS M_i, NINE-POINT CENTERS N_i, and ORTHOCENTERS H_i formed by these triangles are similar to the original quadrilateral. In fact, the triangle formed by the ORTHOCENTERS is congruent to it (Wells 1991, p. 44).

A cyclic quadrilateral with RATIONAL sides a, b, c, and d, DIAGONALS p and q, CIRCUMRADIUS r, and AREA a is given by $a = 25$, $b = 33$, $c = 39$, $d = 65$, $p = 60$, $q = 52$, $r = 65/2$, and $a = 1344$.



Let $ahbo$ be a QUADRILATERAL such that the angles $\angle hab$ and $\angle hob$ are RIGHT ANGLES, then $ahbo$ is a cyclic quadrilateral (Dunham 1990). This is a COROLLARY of the theorem that, in a RIGHT TRIANGLE, the MIDPOINT of the HYPOTENUSE is equidistant from the three VERTICES. Since M is the MIDPOINT of both RIGHT TRIANGLES ΔAHB and ΔBOH, it is equidistant from all four VERTICES, so a CIRCLE centered at M may be drawn through them. This theorem is one of the building blocks of Heron's derivation of HERON'S FORMULA.



An application of BRAHMAGUPTA'S THEOREM gives the pretty result that, for a cyclic quadrilateral with perpendicular diagonals, the distance from the CIRCUMCENTER O to a side is half the length of the opposite side, so in the above figure,

$$OM_{AB} = \tfrac{1}{2}CD = CM_{CD} = DM_{CD}, \quad (9)$$

and so on (Honsberger 1995, pp. 37–8).

Let M_{AC} and M_{BD} be the MIDPOINTS of the diagonals of a cyclic quadrilateral $ABCD$, and let P be the intersection of the diagonals. Then the ORTHOCENTER of TRIANGLE $\Delta PM_{AC}M_{BD}$ is the ANTICENTER T of $ABCD$ (Honsberger 1995, p. 39).

Place four equal CIRCLES so that they intersect in a point. The quadrilateral $ABCD$ is then a cyclic quadrilateral (Honsberger 1991). For a CONVEX cyclic quadrilateral Q, consider the set of CONVEX cyclic quadrilaterals $Q_{\|}$ whose sides are PARALLEL to Q. Then the $Q_{\|}$ of maximal AREA is the one whose DIAGONALS are PERPENDICULAR (Gürel 1996).

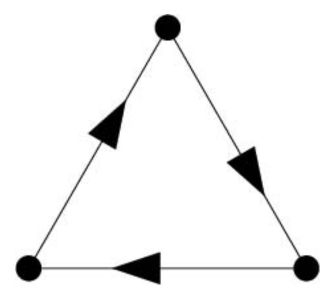
Cyclic Redundancy Check

A sophisticated CHECKSUM (often abbreviated CRC), which is based on the algebra of polynomials over the integers (mod 2). It is substantially more reliable in detecting transmission errors, and is one common error-checking protocol used in modems. The CRC is a form of HASH FUNCTION.



To compare large data blocks using the CRC, first precalculate the CRCs for each block. Two blocks can then be rapidly compared by seeing if their CRCs are equal, saving a great deal of calculation time in most cases. The method is not infallible since for an N-bit checksum, $1/2^N$ of random blocks will have the same checksum for inequivalent data blocks. However, if N is large, the probability that two inequivalent blocks have the same CRC can be made very small.

Cyclically Symmetric Plane Partition

A PLANE PARTITION whose solid Young diagram is invariant under the rotation which cyclically permutes the x-, y-, and z-axes. MACDONALD'S PLANE PARTITION CONJECTURE gives a formula for the number of cyclically symmetric plane partitions (CSPPs) of a given integer whose YOUNG DIAGRAMS fit inside an $n \times n \times n$ box. Macdonald gave a product representation for the power series whose coefficients q^n were the number of such partitions of n.

Cyclic-Inscriptable Quadrilateral

BICENTRIC QUADRILATERAL

Cyclid

CYCLIDE

Cyclide

A pair of focal conics which are the envelopes of two one-parameter families of spheres, sometimes also called a CYCLID. The cyclide is a QUARTIC SURFACE, and the lines of curvature on a cyclide are all straight lines or circular arcs (Pinkall 1986). The STANDARD TORI and their INVERSIONS in an INVERSION SPHERE S centered at a point x_0 and of RADIUS r, given by

$$I(\mathrm{x}_0,\ r) = \mathrm{x}_0 + \frac{\mathrm{x} - \mathrm{x}_0 r^2}{|\mathrm{x} - \mathrm{x}_0|^2},$$

are both cyclides (Pinkall 1986). Illustrated above are RING CYCLIDES, HORN CYCLIDES, and SPINDLE CYCLIDES. The figures on the right correspond to x_0 lying on the torus itself, and are called the PARABOLIC RING CYCLIDE, PARABOLIC HORN CYCLIDE, and PARABOLIC SPINDLE CYCLIDE, respectively.

Cyclidic Coordinates

A general system of fourth-order CURVILINEAR COORDINATES based on the CYCLIDE in which LAPLACE'S EQUATION is SEPARABLE (either simply separable or R-separable). Bôcher (1894) treated all possible systems of this class (Moon and Spencer 1988, p. 49).

Cycloid

The cycloid is the locus of a point on the rim of a CIRCLE of RADIUS a rolling along a straight LINE. It was studied and named by Galileo in 1599. Galileo attempted to find the AREA by weighing pieces of metal cut into the shape of the cycloid. Torricelli, Fermat, and Descartes all found the AREA. The cycloid was also studied by Roberval in 1634, Wren in 1658, Huygens in 1673, and Johann Bernoulli in 1696. Roberval and Wren found the ARC LENGTH (MacTutor Archive). Gear teeth were also made out of cycloids,

as first proposed by Desargues in the 1630s (Cundy and Rollett 1989).

In 1696, Johann Bernoulli challenged other mathematicians to find the curve which solves the BRACHISTOCHRONE PROBLEM, knowing the solution to be a cycloid. Leibniz, Newton, Jakob Bernoulli and L'Hospital all solved Bernoulli's challenge. The cycloid also solves the TAUTOCHRONE PROBLEM, as alluded to in the following passage from *Moby Dick*: "[The try-pot] is also a place for profound mathematical meditation. It was in the left-hand try-pot of the *Pequod*, with the soapstone diligently circling round me, that I was first indirectly struck by the remarkable fact, that in geometry all bodies gliding along a cycloid, my soapstone, for example, will descend from any point in precisely the same time" (Melville 1851). Because of the frequency with which it provoked quarrels among mathematicians in the 17th century, the cycloid became known as the "Helen of Geometers" (Boyer 1968, p. 389).

The cycloid is the CATACAUSTIC of a CIRCLE for a RADIANT POINT on the circumference, as shown by Jakob and Johann Bernoulli in 1692. The CAUSTIC of the cycloid when the rays are parallel to the Y-AXIS is a cycloid with twice as many arches. The RADIAL CURVE of a CYCLOID is a CIRCLE. The EVOLUTE and INVOLUTE of a cycloid are identical cycloids.

If the cycloid has a CUSP at the ORIGIN, its equation in CARTESIAN COORDINATES is

$$x = a\cos^{-1}\left(\frac{a-y}{a}\right) \mp \sqrt{2ay-y^2}. \tag{1}$$

In parametric form, this becomes

$$x = a(t-\sin t) \tag{2}$$

$$y = a(1-\cos t). \tag{3}$$

If the cycloid is upside-down with a cusp at $(0, a)$, (2) and (3) become

$$x = 2a\sin^{-1}\left(\frac{y}{2a}\right) + \sqrt{2ay-y^2} \tag{4}$$

or

$$x = a(t+\sin t) \tag{5}$$

$$y = a(1-\cos t) \tag{6}$$

(sign of $\sin t$ flipped for x).

The DERIVATIVES of the parametric representation (2) and (3) are

$$x' = a(1-\cos t) \tag{7}$$

$$y' = a\sin t \tag{8}$$

$$\frac{dy}{dx} = \frac{y'}{x'} = \frac{a\sin t}{a(1-\cos t)} = \frac{\sin t}{1-\cos t} = \frac{2\sin(\frac{1}{2}t)\cos(\frac{1}{2}t)}{2\sin^2(\frac{1}{2}t)}$$
$$= \cot(\tfrac{1}{2}t) \tag{9}$$

The squares of the derivatives are

$$x'^2 = a^2(1-2\cos t+\cos^2 t) \tag{10}$$

$$y'^2 = a^2\sin^2 t, \tag{11}$$

so the ARC LENGTH of a single cycle is

$$\begin{aligned} L &= \int ds = \int_0^{2\pi} \sqrt{x'^2+y'^2}\,dt \\ &= a\int_0^{2\pi} \sqrt{(1-2\cos t+\cos^2 t)+\sin^2 t}\,dt \\ &= a\sqrt{2}\int_0^{2\pi}\sqrt{1-\cos t}\,dt = 2a\int_0^{2\pi}\sqrt{\frac{1-\cos t}{2}}\,dt \\ &= 2a\int_0^{2\pi}\left|\sin(\tfrac{1}{2}t)\right|\,dt. \end{aligned} \tag{12}$$

Now let $u \equiv t/2$ so $du = dt/2$. Then

$$\begin{aligned} L &= 4a\int_0^{\pi}\sin u\,du = 4a[-\cos u]_0^{\pi} \\ &= -4a[(-1)-1] = 8a. \end{aligned} \tag{13}$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s = 8a\sin^2(\tfrac{1}{4}t) \tag{14}$$

$$\kappa = -\tfrac{1}{4}a\csc(\tfrac{1}{2}t) \tag{15}$$

$$\phi = -\tfrac{1}{2}at. \tag{16}$$

The AREA under a single cycle is

$$\begin{aligned} A &= \int_0^{2\pi} y\,dx = a^2\int_0^{2\pi}(1-\cos\phi)(1-\cos\phi)\,d\phi \\ &= a^2\int_0^{2\pi}(1-\cos\phi)^2\,d\phi \\ &= a^2\int_0^{2\pi}(1-2\cos\phi+\cos^2\phi)\,d\phi \\ &= a^2\int_0^{2\pi}\{1-2\cos\phi+\tfrac{1}{2}[1+\cos(2\phi)]\}\,d\phi \\ &= a^2\int_0^{2\pi}[\tfrac{3}{2}-2\cos\phi+\tfrac{1}{2}\cos(2\phi)]\,d\phi \\ &= a^2[\tfrac{3}{2}\phi-2\sin\phi+\tfrac{1}{4}\sin(2\phi)]_0^{2\pi} \\ &= a^2\,\tfrac{3}{2}\,2\pi = 3\pi a^2. \end{aligned} \tag{17}$$

The NORMAL is

$$\hat{\mathbf{T}} = \frac{1}{\sqrt{2 - 2\cos t}} \begin{bmatrix} 1 - \cos t \\ \sin t \end{bmatrix}. \qquad (18)$$

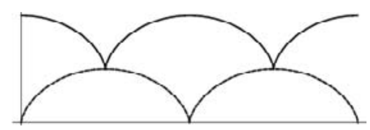
Cycloid Evolute

The EVOLUTE of the CYCLOID



$$x(t) = a(t - \sin t)$$
$$y(t) = a(1 - \cos t)$$

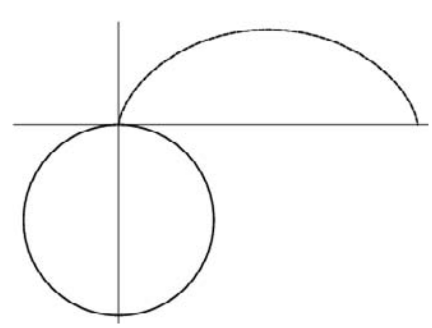
is given by

$$x(t) = a(t + \sin t)$$
$$y(t) = a(\cos t - 1).$$

As can be seen in the above figure, the EVOLUTE is simply a shifted copy of the original CYCLOID, so the CYCLOID is its own EVOLUTE.

Cycloid Involute

The INVOLUTE of the CYCLOID



$$x(t) = a(t - \sin t)$$
$$y(t) = a(1 - \cos t)$$

is given by

$$x(t) = a(t + \sin t)$$
$$y(t) = a(3 + \cos t).$$

As can be seen in the above figure, the INVOLUTE is simply a shifted copy of the original CYCLOID, so the CYCLOID is its own INVOLUTE!

Cycloid Radial Curve

The RADIAL CURVE of the CYCLOID is the CIRCLE

$$x = x_0 + 2a \sin\phi$$

$$y = -2a + y_0 + 2a \cos \phi.$$

Cyclomatic Number

CIRCUIT RANK

Cyclotomic

CYCLOTOMIC POLYNOMIAL

Cyclotomic Equation

The equation

$$x^p = 1,$$

where solutions $\zeta_k = e^{2\pi ik/p}$ are the ROOTS OF UNITY sometimes called DE MOIVRE NUMBERS. Gauss showed that the cyclotomic equation can be reduced to solving a series of QUADRATIC EQUATIONS whenever p is a FERMAT PRIME. Wantzel (1836) subsequently showed that this condition is not only SUFFICIENT, but also NECESSARY. An "irreducible" cyclotomic equation is an expression OF THE FORM

$$\frac{x^p - 1}{x - 1} = x^{p-1} + x^{p-2} + \ldots + 1 = 0,$$

where p is PRIME. Its ROOTS z_i satisfy $|z_i|=1$.

See also CYCLOTOMIC POLYNOMIAL, DE MOIVRE NUMBER, POLYGON, PRIMITIVE ROOT OF UNITY

Wantzel, M. L. "Recherches sur les moyens de reconnaître si un Problème de Géométrie peut se résoudre avec la règle et le compas." *J. Math. pures appliq.* **1**, 366–72, 1836.

Cyclotomic Factorization

$$z^p - y^p = (z - y)(z - \zeta y) \cdots (z - \zeta^{p-1} y),$$

where $\zeta \equiv e^{2\pi i/p}$ (a DE MOIVRE NUMBER) and p is a PRIME.

Cyclotomic Field

The smallest field containing $m \in \mathbb{Z} \geq 1$ with ζ a PRIME ROOT OF UNITY is denoted $\mathbb{R}_m(\zeta)$,

$$x^p + y^p = \prod_{k=1}^{p} (x + \zeta^k y).$$

Specific cases are

$$\mathbb{R}_3 = \mathbb{Q}(\sqrt{-3})$$

$$\mathbb{R}_4 = \mathbb{Q}(\sqrt{-1})$$

$$\mathbb{R}_6 = \mathbb{Q}(\sqrt{-3}),$$

where $\mathbb{Q}$ denotes a QUADRATIC FIELD.

Weiss, E. *Algebraic Number Theory.* New York: Dover, 1998.

Cyclotomic Integer

A number OF THE FORM

$$a_0 + a_1 \zeta + \ldots + a_{p-1} \zeta^{p-1},$$

where

$$\zeta \equiv e^{2\pi i/p}$$

is a DE MOIVRE NUMBER and p is a PRIME NUMBER. Unique factorizations of cyclotomic INTEGERS fail for $p > 23$.

Cyclotomic Invariant

Let p be an ODD PRIME and F_n the CYCLOTOMIC FIELD of p^{n+1}th ROOTS of unity over the rational FIELD. Now let $p^{e(n)}$ be the POWER of p which divides the CLASS NUMBER h_n of F_n. Then there exist INTEGERS μ_p, $\lambda_p \geq 0$ and ν_p such that

$$e(n) = \mu_p p^n + \lambda_p n + \nu_p$$

for all sufficiently large n. For REGULAR PRIMES, $\mu_p = \lambda_p = \nu_p = 0$.

Johnson, W. "Irregular Primes and Cyclotomic Invariants." *Math. Comput.* **29**, 113–20, 1975.

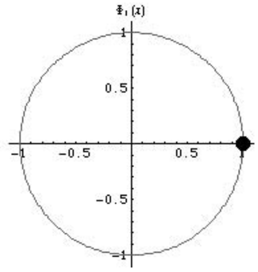
Cyclotomic Number

DE MOIVRE NUMBER, SYLVESTER CYCLOTOMIC NUMBER

Cyclotomic Polynomial

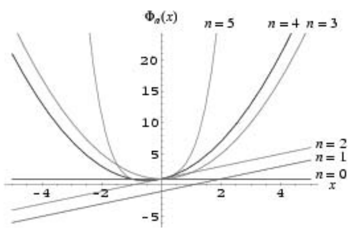
A polynomial given by

$$\Phi_n(x) = \prod_{k=1}^{n}{}' (x - \zeta_k), \quad (1)$$



where ζ_k are the ROOTS OF UNITY in $\mathbb{C}$ given by

$$\zeta_k \equiv e^{2\pi ik/n} \quad (2)$$



and k runs over integers RELATIVELY PRIME to n. The prime may be dropped if the product is instead taken over PRIMITIVE ROOTS OF UNITY, so that

$$\Phi_n(x) = \prod_{\substack{k=1 \\ \text{primitive } \zeta_k}}^{n} (x - \zeta_k). \quad (3)$$

The notation $F_n(x)$ is also frequently encountered. Dickson *et al.* (1923) and Apostol (1975) give extensive bibliographies for cyclotomic polynomials.

$\Phi_n(x)$ is an INTEGER POLYNOMIAL and an IRREDUCIBLE POLYNOMIAL with DEGREE $\phi(n)$, where $\phi(n)$ is the TOTIENT FUNCTION. Cyclotomic polynomials are returned by the *Mathematica* command `Cyclotomic[n, x]`. The roots of cyclotomic polynomials lie on the UNIT CIRCLE in the COMPLEX PLANE, as illustrated above for the first few cyclotomic polynomials.

The first few cyclotomic POLYNOMIALS are

$$\Phi_1(x) = x - 1$$

$$\Phi_2(x) = x + 1$$

$$\Phi_3(x) = x^2 + x + 1$$

$$\Phi_4(x) = x^2 + 1$$

$$\Phi_5(x) = x^4 + x^3 + x^2 + x + 1$$

$$\Phi_6(x) = x^2 - x + 1$$

$$\Phi_7(x) = x^6 + x^5 + x^4 + x^3 + x^2 + x + 1$$

$$\Phi_8(x) = x^4 + 1$$

$$\Phi_9(x) = x^6 + x^3 + 1$$

$$\Phi_{10}(x) = x^4 - x^3 + x^2 - x + 1.$$

If p is an ODD PRIME, then

$$\Phi_p(x) = \frac{x^p - 1}{x - 1} = x^{p-1} + x^{p-2} + \ldots + x + 1 \quad (4)$$

$$\Phi_{2p}(x) = \frac{x^{2p} - 1}{x^p - 1}\frac{x - 1}{x^2 - 1} = x^{p-1} - x^{p-2} + \ldots - x + 1 \quad (5)$$

$$\Phi_{4p}(x) = \frac{x^{4p} - 1}{x^{2p} - 1}\frac{x^2 - 1}{x^4 - 1} = x^{2p-2} - x^{2p-4} + \ldots - x^2 + 1 \quad (6)$$

(Riesel 1994, p. 306). Similarly, for p again an ODD PRIME,

$$x^p - 1 = \Phi_1(x)\Phi_p(x) \quad (7)$$

$$x^{2p} - 1 = \Phi_1(x)\Phi_2(x)\Phi_p(x)\Phi_{2p}(x) \quad (8)$$

$$x^{4p} - 1 = \Phi_1(x)\Phi_4(x)\Phi_2(x)\Phi_p(x)\Phi_{2p}(x)\Phi_{4p}(x). \quad (9)$$

For the first few remaining values of n,

$$x - 1 = \Phi_1(x) \quad (10)$$

$$x^2 - 1 = \Phi_1(x)\Phi_2(x) \quad (11)$$

$$x^4 - 1 = \Phi_1(x)\Phi_2(x)\Phi_4(x) \quad (12)$$

$$x^8 - 1 = \Phi_1(x)\Phi_2(x)\Phi_4(x)\Phi_8(x) \quad (13)$$

$$x^9 - 1 = \Phi_1(x)\Phi_3(x)\Phi_9(x) \quad (14)$$

$$x^{15} - 1 = \Phi_1(x)\Phi_3(x)\Phi_5(x)\Phi_{15}(x) \quad (15)$$

$$x^{16} - 1 = \Phi_1(x)\Phi_2(x)\Phi_4(x)\Phi_8(x)\Phi_{16}(x) \quad (16)$$

$$x^{18} - 1 = \Phi_1(x)\Phi_2(x)\Phi_3(x)_6(x)\Phi_9(x)\Phi_{18}(x) \quad (17)$$

(Riesel 1994, p. 307).

For p a PRIME relatively prime to n,

$$F_{np}(x) = \frac{F_n(x^p)}{F_n(x)}, \quad (18)$$

but if $p|n$,

$$F_{np}(x) = F_n(x^p) \quad (19)$$

(Nagell 1951, p. 160).

An explicit equation for $\Phi_n(x)$ for SQUAREFREE n is given by

$$\Phi_n(x) = \sum_{j=0}^{\phi(n)} a_{nj} z^{\phi(n)-j}, \quad (20)$$

where A_{nj} is calculated using the RECURRENCE RELATION

$$a_{nj} = -\frac{\mu(n)}{j}\sum_{m=0}^{j-1} a_{nm}\mu(\text{GCD}(n, j-m))\phi(\text{GCD}(n, j-m)), \quad (21)$$

with $a_{n0} = 1$, where μ_n is the MÖBIUS FUNCTION and GCD(m, n) is the GREATEST COMMON DENOMINATOR of m and n.

The POLYNOMIAL x^{n-1} can be factored as

$$x^n - 1 = \prod_{d|n} \Phi_d(x), \quad (22)$$

where $\Phi_d(x)$ is a CYCLOTOMIC POLYNOMIAL. Furthermore,

$$x^n + 1 = \frac{x^{2n} - 1}{x^n - 1} = \frac{\prod_{d|2n} \Phi_d(x)}{\prod_{d|n} \Phi_d(x)}. \tag{23}$$

The COEFFICIENTS of the inverse of the cyclotomic POLYNOMIAL

$$\frac{1}{1+x+x^2} = 1 - x + x^3 - x^4 + x^6 - x^7 + x^9 - x^{10} + \ldots$$

$$\equiv \sum_{n=0}^{\infty} c_n x^n \tag{24}$$

can also be computed from

$$c_n = 1 - 2\left\lfloor \tfrac{1}{3}(n+2)\right\rfloor + \left\lfloor \tfrac{1}{3}(n+1)\right\rfloor + \left\lfloor \tfrac{1}{3} n\right\rfloor \tag{25}$$

$$= 1 - 3\left\lfloor \tfrac{1}{3}(n+2)\right\rfloor + \lfloor n \rfloor \tag{26}$$

$$= \frac{2}{\sqrt{3}} \sin[\tfrac{2}{3}\pi(n+1)], \tag{27}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

The LOGARITHM of the cyclotomic polynomial

$$\Phi_n(x) = \prod_{d|n} (1 - x^{n/d})^{\mu(d)} \tag{28}$$

is the MÖBIUS INVERSION FORMULA (Vardi 1991, p. 225).

For p PRIME,

$$\Phi_p(x) = \sum_{k=0}^{p-1} x^k, \tag{29}$$

i.e., the coefficients are all 1. The first cyclotomic polynomial to have a coefficient other than ± 1 and 0 is $\Phi_{105}(x)$, which has coefficients of -2 for x^7 and x^{41}. This is true because 105 is the first number to have three distinct ODD PRIME factors, i.e., T_d (McClellan and Rader 1979, Schroeder 1997). The smallest values of n for which $\Phi_n(x)$ has one or more coefficients ± 1, ± 2, ± 3, ... are 0, 105, 385, 1365, 1785, 2805, 3135, 6545, 6545, 10465, 10465, 10465, 10465, 10465, 11305, ... (Sloane's A013594).

It appears to be true that, for m, $n > 1$, if $\Phi_m(x) + \Phi_n(x)$ factors, then the factors contain a cyclotomic polynomial. For example,

$$\Phi_7(x) + \Phi_{22}(x) = (x^2+1)(x^8 - x^7 + 2x^4 + 2)$$
$$= \Phi_4(x)(x^8 - x^7 + 2x^4 + 2). \tag{30}$$

This observation has been checked up to m, $n = 150$ (C. Nicol). If m and n are prime, then $C_m + C_n$ is irreducible.

Migotti (1883) showed that COEFFICIENTS of $\Phi_{pq}(x)$ for p and q distinct PRIMES can be only 0, ± 1. Lam and Leung (1996) considered

$$\Phi_{pq}(x) \equiv \sum_{k=0}^{pq-1} a_k x^k \tag{31}$$

for p, q PRIME. Write the TOTIENT FUNCTION as

$$\phi(pq) = (p-1)(q-1) = rp + sq \tag{32}$$

and let

$$0 \le k \le (p-1)(q-1), \tag{33}$$

then

1. $a_k = 1$ IFF $k = ip + jq$ for some $i \in [0, r]$ and $j \in [0, s]$,
2. $a_k = -1$ IFF $k + pq = ip + jp$ for $i \in [r+1, q-1]$ and $j \in [s+1, p-1]$,
3. otherwise $a_k = 0$.

The number of terms having $a_k = 1$ is $(r+1)(s+1)$, and the number of terms having $a_k = -1$ is $(p-s-1)(q-r-1)$. Furthermore, assume $q > p$, then the middle COEFFICIENT of Φ_{pq} is $(-1)^r$.

Resultants of cyclotomic polynomials have been computed by Lehmer (1930), Diederichsen (1940), and Apostol (1970). It is known that $\rho(\Phi_k(x), \Phi_n(x)) = 1$ if $(m, n) = 1$, i.e., m and n are relatively prime (Apostol 1975). Apostol (1975) showed that for positive integers m and n and arbitrary nonzero complex numbers a and b,

$$\rho(\Phi_m(ax), \Phi_n(bx))$$
$$= b^{\phi(m)\phi(n)} \prod_{d|n} \left[\Phi_{m/\delta}\left(\frac{a^d}{b^d}\right)\right]^{\mu(n/d)\phi(m)/\phi(m/\delta)}, \tag{34}$$

where $\delta = \mathrm{GCD}(m, d)$ is the GREATEST COMMON DIVISOR of m and d, $\phi(n)$ is the TOTIENT FUNCTION, $\mu(n)$ is the MÖBIUS FUNCTION, and the product is over the divisors of n. If m and n are distinct primes p and q, then (34) simplifies to

$$\rho(\Phi_q(ax), \Phi_p(bx))$$
$$= \begin{cases} \dfrac{a^{pq} - b^{pq}}{a^p - b^p} \dfrac{a - b}{a^q - b^q} & \text{for } a \ne b \\ a^{(p-1)(q-1)} & \text{for } a = b. \end{cases} \tag{35}$$

The following table gives the RESULTANTS $\rho(\Phi_k(x), \Phi_n(x))$ (Sloane's A054372).

$k \backslash n$	1	2	3	4	5	6	7
1	0						
2	2	0					
3	3	1	0				
4	2	2	1	0			

5	5	1	1	1	0			
6	1	3	4	1	1	0		
7	7	1	1	1	1	1	1	0

Cylinder

cylinder

In common usage, the term "cylinder" refers to a SOLID of circular CROSS SECTION in which the centers of the CIRCLES all lie on a single LINE (i.e., a right circular cylinder). In mathematical usage, "cylinder" is commonly taken to refer to only the lateral sides of this solid, excluding the top and bottom caps. If a plane inclined with respect to the caps intersects a cylinder, it does so in an ELLIPSE. The cylinder was extensively studied by Archimedes in his two-volume work *On the Sphere and Cylinder* in ca. 225 BC.

A cylinder is called a right cylinder if it is "straight" in the sense that its CROSS SECTIONS lie directly on top of each other; otherwise, the cylinder is called oblique. The lateral surface of a cylinder of height h and RADIUS r can be described parametrically by

$$x = r \cos\theta \tag{1}$$

$$y = r \sin\theta \tag{2}$$

$$z = z, \tag{3}$$

for $z \in [0, h]$ and $\theta \in [0, 2\pi)$. These are the basis for CYLINDRICAL COORDINATES. The SURFACE AREA (of the sides) and VOLUME of the cylinder of height h and RADIUS r are

$$S = 2\pi r h \tag{4}$$

$$V = \pi r^2 h. \tag{5}$$

Therefore, if top and bottom caps are added, the volume-to-surface area ratio for a cylindrical solid is

$$\frac{V}{S} = \frac{\pi r^2 h}{2\pi rh + 2\pi r^2} = \frac{1}{2}\left(\frac{1}{r} + \frac{1}{h}\right)^{-1}, \tag{6}$$

which is related to the HARMONIC MEAN of the radius r and height h. The fact that

$$\frac{V_{\text{sphere}}}{V_{\text{circumscribed cylinder}} - V_{\text{sphere}}} = \frac{\frac{4}{3}}{2 - \frac{4}{3}} = \frac{\frac{4}{3}}{\frac{2}{3}} = 2 \tag{7}$$

was known to Archimedes (Steinhaus 1983, p. 223).

Using the parametrization

$$x(u, v) = a \cos v \tag{8}$$

$$y(u, v) = a \sin v \tag{9}$$

$$z(u, v) = u \tag{10}$$

gives coefficients of the FIRST FUNDAMENTAL FORM

$$E = 1 \tag{11}$$

$$F = 0 \tag{12}$$

$$G = a^2, \tag{13}$$

the coefficients of the SECOND FUNDAMENTAL FORM

$$e = 0 \tag{14}$$

$$f = 0 \tag{15}$$

$$g = a \tag{16}$$

AREA ELEMENT

$$dS = a\, du \wedge dv, \tag{17}$$

GAUSSIAN CURVATURE

$$K = 0, \tag{18}$$

and MEAN CURVATURE

$$H = \frac{1}{2a}. \tag{19}$$

Cylinder Cutting

The maximum number of pieces into which a cylinder can be divided by n oblique cuts is given by

$$f(n) = \binom{n+1}{3} + n + 1 = \tfrac{1}{6}(n+2)(n+3),$$

where $\binom{a}{b}$ is a BINOMIAL COEFFICIENT. This problem is sometimes also called cake cutting or pie cutting, and has the same solution as SPACE DIVISION BY PLANES. For $n = 1, 2, \ldots$ cuts, the maximum number of pieces is 2, 4, 8, 15, 26, 42, ... (Sloane's A000125).

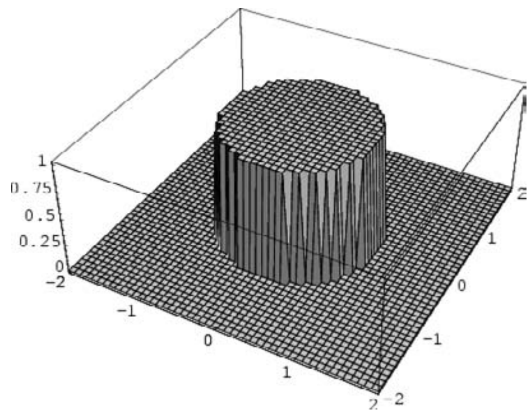
Cylinder Dissection



A cylinder can be dissected into unequal squares, with nine squares required at a minimum. Trivial squarings can be constructed by taking rectangle dissections and matching edges, but there are two nontrivial nine-square tilings (Stewart 1997).

See also MÖBIUS STRIP DISSECTION, PERFECT SQUARE DISSECTION, TORUS DISSECTION

References

Stewart, I. "Squaring the Square." *Sci. Amer.* **277**, 94–6, July 1997.

Cylinder Function

The cylinder function is defined as

$$C(x,\ y) \equiv \begin{cases} 1 & \text{for } \sqrt{x^2+y^2} \leq a \\ 0 & \text{for } \sqrt{x^2+y^2} > a. \end{cases} \tag{1}$$

The BESSEL FUNCTIONS are sometimes also called cylinder functions. To find the FOURIER TRANSFORM of the cylinder function, let

$$k_x = k \cos \alpha \tag{2}$$

$$k_y = k \sin \alpha \tag{3}$$

$$x = r \cos \theta \tag{4}$$

$$y = r \sin \theta. \tag{5}$$

Then

$$\begin{aligned} F(k,\ a) &= \mathscr{F}(C(x,\ y)) \\ &= \int_0^{2\pi} \int_0^a e^{i(k \cos \alpha\ r \cos \theta + k \sin \alpha\ r \sin \theta)} r\, dr\, d\theta \\ &= \int_0^{2\pi} \int_0^a e^{ikr \cos(\theta - \alpha)} r\, dr\, d\theta. \end{aligned} \tag{6}$$

Let $b = \theta - \alpha$, so $db = d\theta$. Then

$$\begin{aligned} F(k,\ a) &= \int_{-\alpha}^{2\pi-\alpha} \int_0^a e^{ikr \cos b} r\, dr\, d\theta \\ &= \int_0^{2\pi} \int_0^a e^{ikr \cos b} r\, dr\, d\theta \\ &= 2\pi \int_0^a J_0(kr) r\, dr, \end{aligned} \tag{7}$$

where $J_0(x)$ is a zeroth order BESSEL FUNCTION OF THE FIRST KIND. Let $u \equiv kr$, so $du = k\, dr$, then

$$\begin{aligned} F(k,\ a) &= \frac{2\pi}{k^2} \int_0^{ka} J_0(u) u\, du = \frac{2\pi}{k^2} [u J_1(u)]_0^{ka} \\ &= \frac{2\pi a}{k} J_1(ka) = 2\pi a^2 \frac{J_1(ka)}{ka}. \end{aligned} \tag{8}$$

As defined by Watson (1966), a "cylinder function" is any function which satisfies the RECURRENCE RELATIONS

$$\mathscr{C}_{\nu-1}(z) + \mathscr{C}_{\nu+1}(z) = \frac{2\nu}{z} \mathscr{C}_\nu(z) \tag{9}$$

$$\mathscr{C}_{\nu-1}(z) - \mathscr{C}_{\nu+1}(z) = 2\mathscr{C}'_\nu(z). \tag{10}$$

This class of functions can be expressed in terms of BESSEL FUNCTIONS.

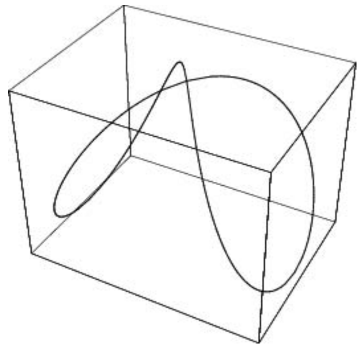
Cylinder-Cylinder Intersection

STEINMETZ SOLID

Cylinder-Plane Intersection



CYLINDRICAL SECTION

Cylinder-Sphere Intersection

The curve formed by the intersection of a CYLINDER and a SPHERE is known as VIVIANI'S CURVE.

The problem of finding the lateral SURFACE AREA of a CYLINDER of radius r internally tangent to a SPHERE of radius R was given in a SANGAKU PROBLEM from 1825.

The easiest way to determine the solution is to solve the simultaneous equations

$$x^2 + y^2 + z^2 = R^2 \tag{1}$$

$$y^2 + [z - (R - r)]^2 = r^2 \tag{2}$$

for x and y,

$$x = \pm\sqrt{2(R - r)(R - z)} \tag{3}$$

$$y = \pm\sqrt{(R - z)(2r - R - z)}. \tag{4}$$

These give the PARAMETRIC EQUATIONS for VIVIANI'S CURVE in this case (left figure). The SURFACE AREA can the be found by constructing a series of curved segments (right figure). The arc length element around the surface of the cylinder at a height z is given by

$$ds = \sqrt{1 + \left(\frac{dy}{dz}\right)^2}\, dz = \frac{r}{\sqrt{(R - z)(2r - R + z)}}. \tag{5}$$

The SURFACE AREA of one quarter of the surface is then

$$S_{1/4} = \int x(z)\, ds$$

$$= \int_{R-2r}^{R} \sqrt{2(R - r)(R - z)}\, \frac{r}{\sqrt{(R - z)(2r - R - z)}}\, dz$$

$$= \int_{R-2r}^{R} r\sqrt{\frac{2(R - r)}{2r - R + z}}\, dz, \tag{6}$$

where some care is needed treating the lower limit,

$$S_{1/4} = \lim_{r' \to r^-} 4r[\sqrt{r(R - r)} - \sqrt{(R - r)(r - r')}]$$

$$= 4r^{3/2}\sqrt{R - r}. \tag{7}$$

The total SURFACE AREA is then

$$S = 4S_{1/4} = 16r^{3/2}\sqrt{R - r} \tag{8}$$

a result obtained in a more roundabout geometric arguments by Rothman (1998). (Note that the answer printed in the original Rothman article was incorrect; the corrected answer has been posted on the Internet version of the article.)

Cylindrical Algebraic Decomposition

This entry contributed by ADAM STRZEBONSKI

Define a cell in $\mathbb{R}^1$ as an open interval or a point. A cell in $\mathbb{R}^{k+1}$ then has one of two forms,

$$\{(x, y) : x \in C, \text{ and } f(x) < y < g(x)\}$$

or

$$\{(x, y) : x \in C, \text{ and } y = f(x)\},$$

where $x = \{x_1, \ldots, x_k\}$, C is a cell in $\mathbb{R}^k$, f and g are either (1) continuous functions on C such that for some polynomials F and G, $F(x, f(x)) = 0$ and $G(x, g(x)) = 0$, or (2) $\pm\infty$, and $f(x) < g(x)$ for all $x \in C$.

A cylindrical algebraic decomposition of $S \subset \mathbb{R}^n$ is a representation of S as a finite union of disjoint cells. Let F be finite set of polynomials in n variables. A cylindrical algebraic decomposition of $S \subset \mathbb{R}^n$ is said to be F-invariant if each of the polynomials from F has a constant sign on each cell of the decomposition.

The cylindrical algebraic decomposition (CAD) algorithm, given a finite set F of polynomials in n variables, computes an F-invariant cylindrical algebraic decomposition of $\mathbb{R}^n$. Given a logical combination of polynomial equations and inequalities in n real unknowns, one can use the CAD algorithm to find a cylindrical algebraic decomposition of its solution set. For example, the decomposition of

$$x^2 + y^2 + z^2 < 1$$

is given by

$$\begin{cases} -1 < x < 1 \\ 1 - \sqrt{1 - x^2} < y < \sqrt{1 - x^2} \\ -\sqrt{1 - x^2 - y^2} < z < \sqrt{1 - x^2 - y^2}. \end{cases}$$

Mathematica 4.0 contains the function `CylindricalAlgebraicDecomposition` which performs cylindrical algebraic decompositions. Although the process is algorithmic, it becomes computationally infeasible for complicated inequalities.

Cylindrical Coordinates

Cylindrical coordinates are a generalization of 2-D POLAR COORDINATES to 3-D by superposing a height (z) axis. Unfortunately, there are a number of different notations used for the other two coordinates. Either r or ρ is used to refer to the radial coordinate and either ϕ or θ to the azimuthal coordinates. Arfken (1985), for instance, uses (ρ, ϕ, z), while Beyer (1987) uses (r, θ, z). In this work, the NOTATION (r, θ, z) is used.

$$r = \sqrt{x^2 + y^2} \tag{1}$$

$$\theta = \tan^{-1}\left(\frac{y}{x}\right) \tag{2}$$

$$z = z, \tag{3}$$

where $r \in [0, \infty)$, $\theta \in [0, 2\pi)$, and $z \in (-\infty, \infty)$. In terms of x, y, and z

$$x = r \cos\theta \tag{4}$$

$$y = r \sin\theta \tag{5}$$

$$z = z. \tag{6}$$

Morse and Feshbach (1953) define the cylindrical coordinates by

$$x = \xi_1 \xi_2 \tag{7}$$

$$y = \xi_1 \sqrt{1 - \xi_2^2} \tag{8}$$

$$z = \xi_3, \tag{9}$$

where $\xi_1 = r$ and $\xi_2 = \cos\theta$. The METRIC elements of the cylindrical coordinates are

$$g_{rr} = 1 \tag{10}$$

$$g_{\theta\theta} = r^2 \tag{11}$$

$$g_{zz} = 1, \tag{12}$$

so the SCALE FACTORS are

$$g_r = 1 \tag{13}$$

$$g_\theta = r \tag{14}$$

$$g_z = 1. \tag{15}$$

The LINE ELEMENT is

$$d\mathbf{s} = dr\,\hat{\mathbf{r}} + r\,d\theta\,\hat{\boldsymbol{\theta}} + dz\,\hat{\mathbf{z}}, \tag{16}$$

and the VOLUME ELEMENT is

$$dV = r\,dr\,d\theta\,dz. \tag{17}$$

The JACOBIAN is

$$\left|\frac{\partial(x, y, z)}{\partial(r, \theta, z)}\right| = r. \tag{18}$$

A CARTESIAN VECTOR is given in CYLINDRICAL COORDINATES by

$$\mathbf{r} = \begin{bmatrix} r\cos\theta \\ r\sin\theta \\ z \end{bmatrix}. \tag{19}$$

To find the UNIT VECTORS,

$$\hat{\mathbf{r}} \equiv \frac{\frac{d\mathbf{r}}{dr}}{\left|\frac{d\mathbf{r}}{dr}\right|} = \begin{bmatrix} \cos\theta \\ \sin\theta \\ 0 \end{bmatrix} \tag{20}$$

$$\hat{\boldsymbol{\theta}} \equiv \frac{\frac{d\mathbf{r}}{d\theta}}{\left|\frac{d\mathbf{r}}{d\theta}\right|} = \begin{bmatrix} -\sin\theta \\ \cos\theta \\ 0 \end{bmatrix} \tag{21}$$

$$\hat{\mathbf{z}} \equiv \frac{\frac{d\mathbf{r}}{dz}}{\left|\frac{d\mathbf{r}}{dz}\right|} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}. \tag{22}$$

Derivatives of unit VECTORS with respect to the coordinates are

$$\frac{\partial \hat{\mathbf{r}}}{\partial r} = \mathbf{0} \tag{23}$$

$$\frac{\partial \hat{\mathbf{r}}}{\partial \theta} = \begin{bmatrix} -\sin\theta \\ \cos\boldsymbol{\theta} \\ 0 \end{bmatrix} = \hat{\theta} \tag{24}$$

$$\frac{\partial \hat{\mathbf{r}}}{\partial z} = \mathbf{0} \tag{25}$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial r} = \mathbf{0} \tag{26}$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial \theta} = \begin{bmatrix} -\cos\theta \\ -\sin\theta \\ 0 \end{bmatrix} = -\hat{\mathbf{r}} \tag{27}$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial z} = \mathbf{0} \tag{28}$$

$$\frac{\partial \hat{z}}{\partial r} = \mathbf{0} \tag{29}$$

$$\frac{\partial \hat{\mathbf{z}}}{\partial \theta} = \mathbf{0} \tag{30}$$

$$\frac{\partial \hat{\mathbf{z}}}{\partial z} = \mathbf{0}. \tag{31}$$

The GRADIENT of a VECTOR FIELD in cylindrical coordinates is given by

$$\nabla \equiv \hat{\mathbf{r}} \frac{\partial}{\partial r} + \hat{\boldsymbol{\theta}} \frac{1}{r} \frac{\partial}{\partial \theta} + \hat{\mathbf{z}} \frac{\partial}{\partial z}, \tag{32}$$

so the GRADIENT components become

$$\nabla_r \hat{\mathbf{r}} = \mathbf{0} \tag{33}$$

$$\nabla_\theta \hat{\mathbf{r}} = \frac{1}{r} \hat{\boldsymbol{\theta}} \tag{34}$$

$$\nabla_z \hat{\mathbf{r}} = \mathbf{0} \tag{35}$$

$$\nabla_r \hat{\boldsymbol{\theta}} = \mathbf{0} \tag{36}$$

$$\nabla_\theta \hat{\boldsymbol{\theta}} = -\frac{1}{r} \hat{\mathbf{r}} \tag{37}$$

$$\nabla_z \hat{\boldsymbol{\theta}} = \mathbf{0} \tag{38}$$

$$\nabla_r \hat{\mathbf{z}} = \mathbf{0} \tag{39}$$

$$\nabla_\theta \hat{\mathbf{z}} = \mathbf{0} \tag{40}$$

$$\nabla_z \hat{\mathbf{z}} = \mathbf{0}. \tag{41}$$

Now, since the CONNECTION COEFFICIENTS are defined by

$$\Gamma^i_{jk} = \hat{\mathbf{x}}_i \cdot (\nabla_k \hat{\mathbf{x}}_j), \tag{42}$$

$$\Gamma^r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & -\frac{1}{r} & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{43}$$

$$\Gamma^\theta = \begin{bmatrix} 0 & \frac{1}{r} & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{44}$$

$$\Gamma^z = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \tag{45}$$

the COVARIANT DERIVATIVES, given by

$$A_{j;\,k} = \frac{1}{g^{kk}} \frac{\partial A_j}{\partial x_k} - \Gamma^i_{jk} A_i, \tag{46}$$

are

$$A_{r;\,r} = \frac{\partial A_r}{\partial r} - \Gamma^i_{rr} A_i = \frac{\partial A_r}{\partial r} \tag{47}$$

$$A_{r;\,\theta} = \frac{1}{r} \frac{\partial A_r}{\partial \theta} - \Gamma^i_{r\theta} A_i = \frac{1}{r} \frac{\partial A_\theta}{\partial r} - \Gamma^\theta_{r\theta} A_\theta$$
$$= \frac{1}{r} \frac{\partial A_r}{\partial \theta} - \frac{A_\theta}{r} \tag{48}$$

$$A_{r;z} = \frac{\partial A_r}{\partial z} - \Gamma^i_{r\,z} A_i = \frac{\partial A_r}{\partial z} \tag{49}$$

$$A_{\theta;\,r} = \frac{\partial A_\theta}{\partial r} \; \Gamma^i_{\theta r} A_i = \frac{\partial A_\theta}{\partial r} \tag{50}$$

$$A_{\theta;\,\theta} = \frac{1}{r}\frac{\partial A_\theta}{\partial\theta} - \Gamma^i_{\theta\theta}A_i = \frac{1}{r}\frac{\partial A_\theta}{\partial_\theta} - \Gamma^r_{\theta\theta}A_r$$
$$= \frac{1}{r}\frac{\partial A_\theta}{\partial\theta} + \frac{A_r}{r} \tag{51}$$

$$A_{\theta;\,z} = \frac{\partial A_\theta}{\partial z} - \Gamma^i_{\theta z}A_i = \frac{\partial A_\theta}{\partial z} \tag{52}$$

$$A_{z;\,r} = \frac{\partial A_z}{\partial r} - \Gamma^i_{zr}A_i = \frac{\partial A_z}{\partial r} \tag{53}$$

$$A_{z;\,\theta} = \frac{\partial A_z}{\partial\theta} - \Gamma^i_{z\theta}A_i = \frac{1}{r}\frac{\partial A_z}{\partial\theta} \tag{54}$$

$$A_{z;\,z} = \frac{\partial A_z}{\partial z} - \Gamma^i_{zz}A_i = \frac{\partial A_z}{\partial z}. \tag{55}$$

Cross products of the coordinate axes are

$$\hat{\mathbf{r}} \times \hat{\mathbf{z}} = -\hat{\theta} \tag{56}$$

$$\hat{\boldsymbol{\theta}} \times \hat{\mathbf{z}} = \hat{\mathbf{r}} \tag{57}$$

$$\hat{\mathbf{r}} \times \hat{\boldsymbol{\theta}} = \hat{\mathbf{z}}. \tag{58}$$

The commutation coefficients are given by

$$c^{\mu}_{\alpha\beta}\vec{e}_\mu = [\vec{e}_\alpha,\ \vec{e}_\beta] = \nabla_\alpha\vec{e}_\beta - \nabla_\beta\vec{e}_\alpha, \tag{59}$$

But

$$[\hat{\mathbf{r}},\ \hat{\mathbf{r}}] = [\hat{\boldsymbol{\theta}},\ \hat{\boldsymbol{\theta}}] = [\hat{\boldsymbol{\phi}},\ \hat{\boldsymbol{\phi}}] = 0, \tag{60}$$

so $c^{\alpha}_{rr} = c^{\alpha}_{\theta\theta} = c^{\alpha}_{\phi\phi} = 0$, where $\alpha = r,\ \theta,\ \phi$. Also

$$[\hat{\mathbf{r}},\ \hat{\boldsymbol{\theta}}] = -[\hat{\boldsymbol{\theta}},\ \hat{\mathbf{r}}] = \nabla_r\hat{\boldsymbol{\theta}} - \nabla_\theta\hat{\mathbf{r}} = 0 - \frac{1}{r}\ \hat{\boldsymbol{\theta}} = -\frac{1}{r}\ \hat{\boldsymbol{\theta}}, \tag{61}$$

so $c^{\theta}_{r\theta} = -c^{\theta}_{\theta r} = -\frac{1}{r}$, $c^{r}_{r\theta} = c^{\phi}_{r\theta} = 0$. Finally,

$$[\hat{\mathbf{r}},\ \hat{\boldsymbol{\phi}}] = [\hat{\boldsymbol{\theta}},\ \hat{\boldsymbol{\phi}}] = 0. \tag{62}$$

Summarizing,

$$c^r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{63}$$

$$c^\theta = \begin{bmatrix} 0 & -\frac{1}{r} & 0 \\ \frac{1}{r} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \tag{64}$$

$$c^\phi = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}. \tag{65}$$

Time derivatives of the vector are

$$\dot{\mathbf{r}} = \begin{bmatrix} \cos\theta\,\dot{r} - r\sin\theta\,\dot{\theta} \\ \sin\theta\,\dot{r} + r\cos\theta\,\dot{\theta} \\ \dot{z} \end{bmatrix} = \dot{r}\hat{\mathbf{r}} + r\dot{\theta}\hat{\boldsymbol{\theta}} + \dot{z}\hat{\mathbf{z}} \tag{66}$$

$$\ddot{\mathbf{r}} =$$
$$\begin{bmatrix} -\sin\theta\,\dot{r}\dot{\theta} + \cos\theta\ddot{r} - \sin\theta\dot{r}\dot{\theta} - r\cos\theta\,\dot{\theta}^2 - r\sin\theta\,\ddot{\theta} \\ \cos\theta\,\dot{r}\dot{\theta} + \sin\theta\ddot{r} + \cos\theta\,\dot{r}\dot{\theta} - r\sin\theta\,\dot{\theta}^2 + r\cos\theta\,\ddot{\theta} \\ \ddot{z} \end{bmatrix}$$
$$= \begin{bmatrix} -2\sin\theta\,\dot{r}\dot{\theta} + \cos\theta\ddot{r} - r\cos\theta\,\dot{\theta}^2 - r\sin\theta\,\ddot{\theta} \\ 2\cos\theta\,\dot{r}\dot{\theta} + \sin\theta\,\ddot{r} - r\sin\theta\,\dot{\theta}^2 + r\cos\theta\,\ddot{\theta} \\ \ddot{z} \end{bmatrix}$$
$$= (\ddot{r} - r\dot{\theta}^2)\hat{\mathbf{r}} + (2\dot{r}\dot{\theta} + r\ddot{\theta})\hat{\boldsymbol{\theta}} + \ddot{z}\hat{\mathbf{z}}. \tag{67}$$

Speed is given by

$$v \equiv |\dot{\mathbf{r}}| = \sqrt{\dot{r}^2 + r^2\dot{\theta}^2 + \dot{z}^2}. \tag{68}$$

Time derivatives of the unit vectors are

$$\dot{\hat{\mathbf{r}}} = \begin{bmatrix} -\sin\theta\,\dot{\theta} \\ \cos\theta\,\dot{\theta} \\ 0 \end{bmatrix} = \dot{\theta}\hat{\boldsymbol{\theta}} \tag{69}$$

$$\dot{\hat{\boldsymbol{\theta}}} = \begin{bmatrix} -\cos\theta\,\dot{\theta} \\ -\sin\theta\,\dot{\theta} \\ 0 \end{bmatrix} = -\dot{\theta}\hat{\mathbf{r}} \tag{70}$$

$$\dot{\hat{\mathbf{z}}} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} = \mathbf{0}. \tag{71}$$

Cross products of the axes are

$$\hat{\mathbf{r}} \times \hat{\mathbf{z}} = -\hat{\boldsymbol{\theta}} \tag{72}$$

$$\hat{\boldsymbol{\theta}} \times \hat{\mathbf{z}} = \hat{\mathbf{r}} \tag{73}$$

$$\hat{\mathbf{r}} \times \hat{\boldsymbol{\theta}} = \hat{\mathbf{z}}. \tag{74}$$

The convective derivative is

$$\frac{D\dot{\mathbf{r}}}{Dt} \equiv \left(\frac{\partial}{\partial t} + \dot{\mathbf{r}}\cdot\nabla\right)\dot{\mathbf{r}} = \frac{\partial\dot{\mathbf{r}}}{\partial t} + \dot{\mathbf{r}}\cdot\nabla\dot{\mathbf{r}}. \tag{75}$$

To rewrite this, use the identity

$$\nabla(\mathbf{A}\cdot\mathbf{B}) = \mathbf{A}\times(\nabla\times\mathbf{B}) + \mathbf{B}\times(\nabla\times\mathbf{A}) + (\mathbf{A}\cdot\nabla)\mathbf{B}$$
$$+ (\mathbf{B}\cdot\nabla)\mathbf{A} \tag{76}$$

and set $\mathbf{A} = \mathbf{B}$, to obtain

$$\nabla(\mathbf{A}\cdot\mathbf{A}) = 2\mathbf{A}\times(\nabla\times\mathbf{A}) + 2(\mathbf{A}\cdot\nabla)\mathbf{A}, \tag{77}$$

so

$$(\mathbf{A}\cdot\nabla)\mathbf{A} = (\tfrac{1}{2}\mathbf{A}^2) - \mathbf{A}\times(\nabla\times\mathbf{A}). \tag{78}$$

Then

$$\frac{D\dot{\mathbf{r}}}{Dt} = \ddot{\mathbf{r}} + \nabla(\tfrac{1}{2}\dot{\mathbf{r}}^2) - \dot{\mathbf{r}}\times(\nabla\times\dot{\mathbf{r}})$$
$$= \ddot{\mathbf{r}} + (\nabla\times\dot{\mathbf{r}})\times\dot{\mathbf{r}} + \nabla(\tfrac{1}{2}\dot{\mathbf{r}}^2). \tag{79}$$

The curl in the above expression gives

$$\nabla\times\dot{\mathbf{r}} = \frac{1}{r}\frac{\partial}{\partial r}(r^2\dot{\theta})\hat{\mathbf{z}} = 2\dot{\theta}\hat{\mathbf{z}}, \tag{80}$$

so

$$-\dot{\mathbf{r}} \times (\nabla \times \dot{\mathbf{r}}) = -2\dot{\theta}(\dot{r}\hat{\mathbf{r}} \times \hat{\mathbf{z}} + r\dot{\theta}\hat{\boldsymbol{\theta}} \times \hat{\mathbf{z}}) = -2\dot{\theta}(-\dot{r}\hat{\boldsymbol{\theta}} + r\dot{\theta}\hat{\mathbf{r}})$$
$$= 2\dot{r}\dot{\theta}\hat{\boldsymbol{\theta}} - 2r\dot{\theta}^2\hat{\mathbf{r}}. \quad (81)$$

We expect the gradient term to vanish since SPEED does not depend on position. Check this using the identity $\nabla(f^2) = 2f\nabla f$,

$$\nabla(\tfrac{1}{2}\,\dot{\mathbf{r}}^2) = \tfrac{1}{2}\,\nabla(\dot{r}^2 + r^2\dot{\theta}^2 + \dot{z}^2) = \dot{r}\nabla\dot{r} + r\dot{\theta}\nabla(r\dot{\theta}) + \dot{z}\nabla\dot{z}. \quad (82)$$

Examining this term by term,

$$\dot{r}\nabla\dot{r} = \dot{r}\,\frac{\partial}{\partial t}\,\nabla r = \dot{r}\,\frac{\partial}{\partial t}\,\hat{\mathbf{r}} = \dot{r}\dot{\hat{\mathbf{r}}} = \dot{r}\dot{\theta}\hat{\boldsymbol{\theta}} \quad (83)$$

$$r\dot{\theta}\nabla(r\dot{\theta}) = r\dot{\theta}\left[r\,\frac{\partial}{\partial t}\,\nabla\theta + \dot{\theta}\nabla r\right] = r\dot{\theta}\left[r\,\frac{\partial}{\partial t}\left(\frac{1}{r}\,\hat{\boldsymbol{\theta}}\right) + \dot{\theta}\hat{\mathbf{r}}\right]$$
$$= r\dot{\theta}\left[r\left(-\frac{1}{r^2}\,\dot{r}\hat{\boldsymbol{\theta}} + \frac{1}{r}\,\dot{\hat{\boldsymbol{\theta}}}\right) + \dot{\theta}\hat{\mathbf{r}}\right]$$
$$= -\dot{\theta}\dot{r}\hat{\boldsymbol{\theta}} + r\dot{\theta}(-\dot{\theta}\hat{\mathbf{r}}) + r\dot{\theta}^2\hat{\mathbf{r}} = -\dot{\theta}\dot{r}\hat{\boldsymbol{\theta}} \quad (84)$$

$$\dot{z}\nabla\dot{z} = \dot{z}\,\frac{\partial}{\partial t}\,\nabla z = \dot{z}\,\frac{\partial}{\partial t}\,\hat{\mathbf{z}} = \dot{z}\dot{\hat{\mathbf{z}}} = \mathbf{0}, \quad (85)$$

so, as expected,

$$\nabla(\tfrac{1}{2}\,\dot{\mathbf{r}}^2) = \mathbf{0}. \quad (86)$$

We have already computed $\ddot{\mathbf{r}}$, so combining all three pieces gives

$$\frac{D\dot{\mathbf{r}}}{Dt} = (\ddot{r} - r\dot{\theta}^2 - 2r\dot{\theta}^2)\hat{\mathbf{r}} + (2\dot{r}\dot{\theta} + 2\dot{r}\dot{\theta} + r\ddot{\theta})\hat{\boldsymbol{\theta}} + \ddot{z}\hat{\mathbf{z}}$$
$$= (\ddot{r} - 3r\dot{\theta}^2)\hat{r} + (4\dot{r}\dot{\theta} + r\ddot{\theta})\hat{\boldsymbol{\theta}} + \ddot{z}\hat{\mathbf{z}}. \quad (87)$$

The DIVERGENCE is

$$\nabla \cdot A = A^r_{;r} = A^r_{,r} + (\Gamma^r_{rr}A^t + \Gamma^r_{\theta r}A^\theta + \Gamma^r_{zr}A^z) + A^\theta_{,\theta}$$
$$+ (\Gamma^\theta_{r\theta}A^r + \Gamma^\theta_{\theta\theta}A^\theta + \Gamma^\theta_{z\theta}A^z)$$
$$+ A^z_{,z} + (\Gamma^z_{rz}A^r + \Gamma^z_{\theta z}A^\theta + \Gamma^z_{zz}A^z)$$
$$= A^r_{,r} + A^\theta_{,\theta} + A^z_{,z} + (0+0+0) + \left(\frac{1}{r} + 0 + 0\right)$$
$$+ (0+0+0)$$
$$= \frac{1}{g_r}\,\frac{\partial}{\partial r}\,A^r + \frac{1}{g_\theta}\,\frac{\partial}{\partial \theta}\,A^\theta + \frac{1}{g_z}\,\frac{\partial}{\partial z}\,A^z + \frac{1}{r}\,A^r$$
$$= \left(\frac{\partial}{\partial r} + \frac{1}{r}\right)A^r + \frac{1}{r}\,\frac{\partial}{\partial \theta}\,A^\theta + \frac{\partial}{\partial z}\,A^z, \quad (88)$$

or, in VECTOR notation

$$\nabla \cdot \mathbf{F} = \frac{1}{r}\,\frac{\partial}{\partial r}(rF_r) + \frac{1}{r}\,\frac{\partial F_\theta}{\partial \theta} + \frac{\partial F_z}{\partial z}. \quad (89)$$

The CROSS PRODUCT is

$$\nabla \times \mathbf{F} = \left(\frac{1}{r}\,\frac{\partial F_z}{\partial \theta} - \frac{\partial F_\theta}{\partial z}\right)\hat{\mathbf{r}} + \left(\frac{\partial F_r}{\partial z} - \frac{\partial F_z}{\partial r}\right)\hat{\boldsymbol{\theta}}$$
$$+ \frac{1}{r}\left[\frac{\partial}{\partial r}(rF_\theta) - \frac{\partial F_r}{\partial \theta}\right]\hat{\mathbf{z}}. \quad (90)$$

The scalar LAPLACIAN is

$$\nabla^2 f \equiv \frac{1}{r}\,\frac{\partial}{\partial r}\left(r\,\frac{\partial f}{\partial r}\right) + \frac{1}{r^2}\,\frac{\partial^2 f}{\partial \theta^2} + \frac{\partial^2 f}{\partial z^2}$$
$$= \frac{\partial^2 f}{\partial r^2} + \frac{1}{r}\,\frac{\partial f}{\partial r} + \frac{1}{r^2}\,\frac{\partial^2 f}{\partial \theta^2} + \frac{\partial^2 f}{\partial z^2}. \quad (91)$$

The vector LAPLACIAN is

$$\nabla^2\mathbf{v} = \begin{bmatrix} \frac{\partial^2 v_r}{\partial r^2} + \frac{1}{r^2}\,\frac{\partial^2 v_r}{\partial \phi^2} + \frac{\partial^2 v_r}{z^2} + \frac{1}{r}\,\frac{\partial v_r}{\partial r} - \frac{2}{r^2}\,\frac{\partial v_\phi}{\partial \phi} - \frac{v_r}{r^2} \\ \frac{\partial^2}{\partial r^2} + \frac{1}{r^2}\,\frac{\partial^2 v_\phi}{\partial \phi^2} + \frac{\partial^2 v_\phi}{\partial z^2} + \frac{1}{r}\,\frac{\partial v_\phi}{\partial r} + \frac{2}{r^2}\,\frac{\partial v_r}{\partial \phi} - \frac{v_\phi}{r^2} \\ \frac{\partial^2 v_z}{\partial r^2} + \frac{1}{r^2}\,\frac{\partial^2 v_z}{\partial \phi^2} + \frac{\partial^2 v_z}{\partial z^2} + \frac{1}{r}\,\frac{\partial v_z}{\partial r} \end{bmatrix}. \quad (92)$$

The HELMHOLTZ DIFFERENTIAL EQUATION is separable in cylindrical coordinates and has STÄCKEL DETERMINANT $S = 1$ (for r, θ, z) or $S = 1/(1 - \xi_2^2)$ (for Morse and Feshbach's ξ_1, ξ_2, ξ_3).

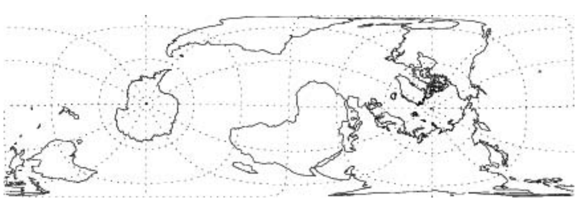
Cylindrical Equal-Area Projection

The MAP PROJECTION having transformation equa-

tions

$$x = (\lambda - \lambda_0)\cos\phi_s \quad (1)$$

$$y = \sin\phi \sec\phi_s \quad (2)$$



for the normal aspect, where λ is the LONGITUDE, λ_0 is the standard LONGITUDE (horizontal center of the projection), ϕ is the LATITUDE, and ϕ_s is the so-called "standard latitude." The inverse transformation equations for the normal aspect are

$$\phi = \sin^{-1}(y\cos\phi_s) \quad (3)$$

$$\lambda = x\sec\phi_s + \lambda_0. \quad (4)$$

Special cases of cylindrical equal-area projections are summarized in the following table (Maling 1992).

ψ_s	MAP PROJECTION
0°	LAMBERT CYLINDRICAL EQUAL-AREA PROJECTION
30°	BEHRMANN CYLINDRICAL EQUAL-AREA PROJECTION
37.383°	TRISTAN EDWARDS PROJECTION
44.138°	PETERS PROJECTION
45°	GALL ORTHOGRAPHIC PROJECTION
50°	BALTHASART PROJECTION

An oblique form of the cylindrical equal-area projection is given by the equations

$$\lambda_p = \tan^{-1}\left(\frac{\cos\phi_1\sin\phi_2\cos\lambda_1 - \sin\phi_1\cos\phi_2\cos\lambda_2}{\sin\phi_1\cos\phi_2\sin\lambda_2 - \cos\phi_1\sin\phi_2\sin\lambda_1}\right) \quad (5)$$

$$\phi_p = \tan^{-1}\left[-\frac{\cos(\lambda_p - \lambda_1)}{\tan\phi_1}\right], \quad (6)$$

and the inverse FORMULAS are

$$\phi = \sin^{-1}(y\sin\phi_p + \sqrt{1-y^2}\cos\phi_p\sin x) \quad (7)$$

$$\lambda = \lambda_0 + \tan^{-1}\left(\frac{\sqrt{1-y^2}\sin\phi_p\sin x - y\cos\phi_p}{\sqrt{1-y^2}\cos x}\right). \quad (8)$$

A transverse form of the cylindrical equal-area projection is given by the equations

$$x = \cos\phi\sin(\lambda - \lambda_0) \quad (9)$$

$$y = \tan^{-1}\left[\frac{\tan\phi}{\cos(\lambda - \lambda_0)}\right] - \phi_0, \quad (10)$$

and the inverse FORMULAS are

$$\phi = \sin^{-1}[\sqrt{1-x^2}\sin(y+\phi_0)] \quad (11)$$

$$\lambda = \lambda_0 + \tan^{-1}\left[\frac{x}{\sqrt{1-x^2}}\cos(y+\phi_0)\right]. \quad (12)$$

BESSEL FUNCTION OF THE FIRST KIND

Cylindrical Hoof

CYLINDRICAL WEDGE

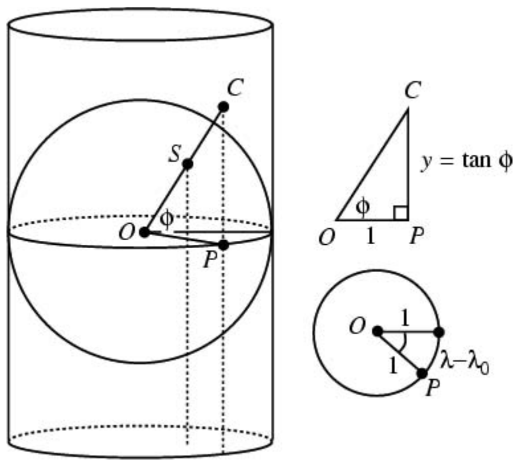
Cylindrical Parts

The cylindrical parts of a system of real algebraic equations and inequalities in variables $\{x_1, \ldots, x_n\}$ are the terms

$$f_1 \leq x_1 \leq g_1$$
$$f_2(x_1) \leq x_2 \leq g_2(x_1)$$
$$\vdots$$
$$f_n(x_1, x_2, \ldots, x_n) \leq x_n \leq g_n(x_1, \ldots, x_{n-1}),$$

where '≤' is one of <, ≤, or =, and f_i and g_i are $\pm\infty$ or algebraic expressions in variables $\{x_1, \ldots, x_{i-1}\}$ that are real-valued for all $(i-1)$-tuples of real numbers $\{a_1, \ldots, a_{i-1}\}$ satisfying

$$f_1 \leq a_1 \leq g_1$$
$$f_2(a_1) \leq a_2 \leq g_2(a_2)$$
$$\vdots$$
$$f_{i-1}(a_1, \ldots, a_{i-2}) \leq a_{i-1} \leq g_{i-1}(a_1, \ldots, a_{i-2}).$$



The CONJUNCTION of a finite number of disjoint cylindrical parts is called a CYLINDRICAL ALGEBRAIC DECOMPOSITION.

See also CYLINDRICAL ALGEBRAIC DECOMPOSITION

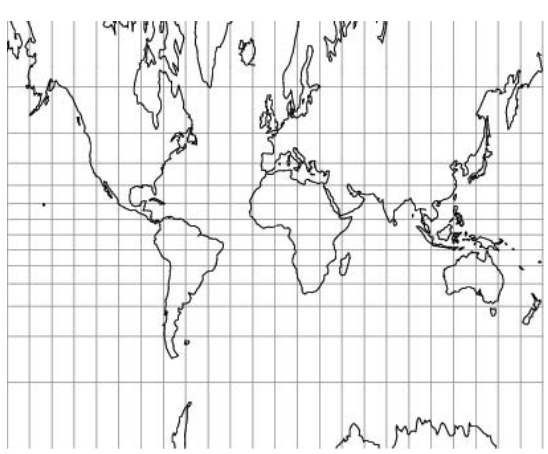
Cylindrical Projection



A cylindrical projection of points on a unit sphere centered at O consists of extending the line OS for each point S until it intersects a cylinder tangent to the sphere at its equator at a corresponding point C. If the sphere is tangent to the cylinder at longitude λ_0, then a point on the sphere with latitude ϕ and longitude λ is mapped to a point on the cylinder with height tan ϕ.

Unwrapping and flattening out the cylinder then gives the Cartesian coordinates

$$x = \lambda - \lambda_0 \tag{1}$$

$$y = \tan \phi. \tag{2}$$

The cylindrical projection of the Earth is illustrated above.

This form of the projection, however, is seldom used in practice, and the term "cylindrical projection" is used instead to refer to *any* projection in which lines of longitude are mapped to equally spaced parallel lines and lines of latitude (parallels) are mapped to parallel lines with arbitrary mathematically spaced separations (Snyder 1987, p. 5). For example, the common MERCATOR PROJECTION uses the complicated transformation

$$y = \ln[\tan(\tfrac{1}{4}\pi + \tfrac{1}{2}\phi)] \tag{3}$$

instead of tan ϕ in order to achieve certain desirable properties in the projection.

Craig (1882) used the term "cylindric" instead of "cylindrical" (Lee 1944), but this convention did not catch on.

Cylindrical Section

The intersection of a PLANE with a right circular CYLINDER is a CIRCLE (if the plane is at a right angle to the axis), an ELLIPSE, or, if the plane is parallel to the axis, a single line (if the plane is tangent to the cylinder), pair of parallel lines bounding an infinite rectangle (if the plane cuts the cylinder), or no intersection at all (if the plane missed the cylinder entirely; Hilbert and Cohn-Vossen 1999, pp. 7–).

The volume of the cylindrical section can be obtained instantly by noting that two such sections can be fitted together to form a cylinder of radius R and

height $h_1 + h_2$, so the volume of the original wedge is half that of the cylinder of height $h_1 + h_2$. The volume can be found directly through integration by noting that the height in polar and Cartesian coordinates is given by

$$h(r, \theta) = h_1 + \frac{1}{2}\left(1 + \frac{r}{R}\cos\theta\right)(h_2 - h_1) \quad (1)$$

$$h(x, y) = h_1 + \frac{1}{2}\left(1 + \frac{x}{R}\right)(h_2 - h_1), \quad (2)$$

so

$$V = \int_0^R \int_0^{2\pi} \int_0^{h(r,\theta)} r\, dr\, d\theta\, dz \quad (3)$$

$$= \int_{-R}^{R} \int_{-\sqrt{R^2-x^2}}^{\sqrt{R^2-x^2}} \int_0^{h(x,y)} dx\, dy\, dz, \quad (4)$$

giving (1). Similarly, the volume-weighted coordinates are given by

$$\langle x\rangle = \tfrac{1}{8}\pi R^3(h_2 - h_1) \quad (5)$$

$$\langle y\rangle = 0 \quad (6)$$

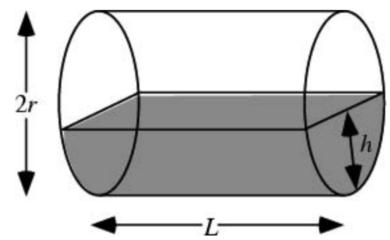
$$\langle z\rangle = \tfrac{1}{32}\pi R^2(5h_1^2 + 6h_1h_2 + 5h_2^2), \quad (7)$$

so the centroids are given by

$$\bar{x} = \frac{\langle x\rangle}{V} = \frac{R(h_2 - h_1)}{4(h_1 + h_2)} \quad (8)$$

$$\bar{y} = \frac{\langle y\rangle}{V} = 0 \quad (9)$$

$$\bar{z} = \frac{\langle z\rangle}{V} = \frac{5h_1^2 + 6h_1h_2 + 5h_2^2}{16(h_1 + h_2)}, \quad (10)$$



(cf. the strange parameterization used by Harris and Stocker 1998, p. 103).

Cylindrical Segment

The solid portion of a cylinder below a cutting plane which is oriented parallel to the cylinder's axis of symmetry (i.e., a portion of a horizontal cylindrical tank which is partially filled with fluid).

The solid cut from a circular cylinder by a tilted plane which does not cut the base (sometimes called a truncated cylinder) has volume

$$V = \tfrac{1}{2}\pi R^2(h_1 + h_2), \quad (1)$$

lateral surface area

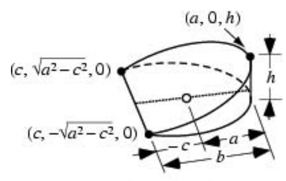
$$S_L = \pi R(h_1 + h_2), \quad (2)$$

and top surface area

$$S_T = \pi R\sqrt{R^2 + \tfrac{1}{4}(h_2 - h_1)^2} \quad (3)$$

(Harris and Stocker 1998, p. 103).
For a cylinder of radius r and length L, the volume $V(L, r, h)$ of the cylindrical segment is given by multiplying the area of a circular segment of height h by L,

$$V(L, r, h) = L\left[r^2\cos^{-1}\left(\frac{r-h}{r}\right) - (r-h)\sqrt{2rh - h^2}\right],$$



plotted above. Note that the above equation gives $V(h=0) = 0$, $V(h=r) = \pi r^2 L/2$, and $V(h=2r) = \pi r^2 L$, as it must.

See also Cylindrical Wedge, Sector, Segment, Spherical Segment

Cylindrical Surface

Generalized Cylinder

Cylindrical Wedge

cylindrical wedge

A wedge is cut from a CYLINDER by slicing with a plane that intersects the base of the cylinder. The VOLUME of a cylindrical wedge can be found by noting that the plane cutting the cylinder passes through the three points illustrated above (with $c = a - b$), so the three-point form of the plane gives the equation

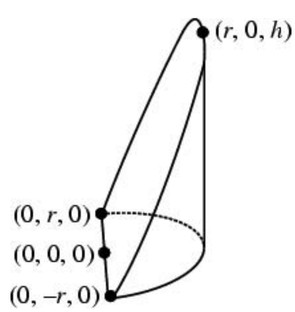
$$-hx + bz + (a - b)h = 0. \tag{1}$$

Solving for z gives

$$z = \frac{h(x - a + b)}{b}. \tag{2}$$

The volume is therefore

$$V = 2\int_0^{\sqrt{a^2-x^2}}\int_{a-b}^{a} \frac{h(x+b-a)}{b}\,dx\,dy \tag{3}$$



$$= \frac{h}{6b}\Big[2\sqrt{(2a-b)b}(3a^2 - 2ab + b^2) - 3\pi a^2(a-b)$$

$$+6a^2(a-b)\tan^{-1}\left(\frac{a-b}{\sqrt{(2a-b)b}}\right)\Big], \tag{4}$$

and the lateral SURFACE AREA

$$S_L = \frac{2h}{b} \times \left[\sqrt{(2a-b)b} - a(a-b)\cot^{-1}\left(\frac{a-b}{\sqrt{(2a-b)b}}\right)\right], \tag{5}$$

(apparently given incorrectly by Harris and Stocker 1998, p. 104).

A special case of the cylindrical wedge, also called a cylindrical hoof, is a wedge passing through a DIAMETER of the base (so that $a = b$). Let the height of the wedge be h and the radius of the CYLINDER from which it is cut r. Then plugging the points $(0, -r, 0)$, $(0, r, 0)$, and $(r, 0, h)$ into the 3-point equation for a PLANE gives the equation for the plane as

$$hx - rz = 0. \tag{6}$$

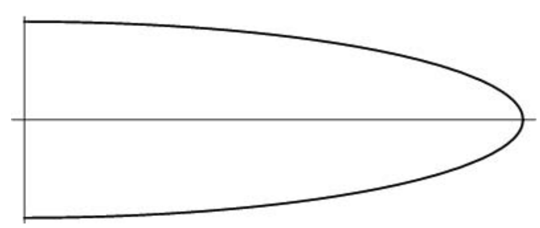
combining with the equation of the CIRCLE which describes the curved part remaining of the cylinder (and writing $t = x$ then gives the PARAMETRIC EQUATIONS of the "tongue" of the wedge as

$$x = t \tag{7}$$

$$y = \pm\sqrt{r^2 - t^2} \tag{8}$$

$$z = \frac{ht}{r} \tag{9}$$

for $t \in [0, r]$. To examine the form of the tongue, it needs to be rotated into a convenient plane. This can be accomplished by first rotating the plane of the curve by 90° about the X-AXIS using the ROTATION MATRIX $R_x(90°)$ and then by the ANGLE



$$\theta = \tan^{-1}\left(\frac{h}{r}\right) \tag{10}$$

above the Z-AXIS. The transformed plane now rests in the xz-plane and has PARAMETRIC EQUATIONS

$$x = \frac{t\sqrt{h^2 + r^2}}{r} \tag{11}$$

$$z = \pm\sqrt{r^2 - t^2} \tag{12}$$

and is shown below.

The length of the tongue (measured down its middle) is obtained by plugging $t = r$ into the above equation for x, which becomes

$$L = \sqrt{h^2 + r^2} \tag{13}$$

(and which follows immediately from the PYTHAGOREAN THEOREM). The VOLUME of the wedge is given by

$$V = \tfrac{2}{3} r^2 h \tag{14}$$

and the lateral SURFACE AREA by

$$S_L = 2rh. \tag{15}$$

While the centroid of the general cylindrical wedge is complicated for $a \neq b$, for the cylindrical hoof, the

centroid is given by

$$\bar{x} = \int_{a-b}^{a} \int_{-\sqrt{a^2-x^2}}^{\sqrt{a^2-x^2}} \int_{0}^{h(b-a+x)/b} \mathbf{x}\, dz\, dy\, dz, \qquad (16)$$

giving

$$\langle x \rangle = \frac{3}{16} \pi r \qquad (17)$$

$$\langle y \rangle = 0 \qquad (18)$$

$$\langle z \rangle = \frac{3}{32} \pi h. \qquad (19)$$

d'Alembert's Solution

The method of d'Alembert provides a solution to the one-dimensional WAVE EQUATION

$$\frac{\partial^2 y}{\partial x^2} = \frac{1}{c^2}\frac{\partial^2 y}{\partial t^2} \quad (1)$$

that models vibrations of a string.

The general solution can be obtained by introducing new variables $\xi = x - ct$ and $\eta = x + ct$, and applying the CHAIN RULE to obtain

$$\frac{\partial}{\partial x} = \frac{\partial \xi}{\partial x}\frac{\partial}{\partial \xi} + \frac{\partial \eta}{\partial x}\frac{\partial}{\partial \eta} \quad (2)$$

$$= \frac{\partial}{\partial \xi} + \frac{\partial}{\partial \eta} \quad (3)$$

$$\frac{\partial}{\partial t} = \frac{\partial \xi}{\partial t}\frac{\partial}{\partial \xi} + \frac{\partial \eta}{\partial t}\frac{\partial}{\partial \eta} \quad (4)$$

$$= -c\frac{\partial}{\partial \xi} + c\frac{\partial}{\partial \eta}. \quad (5)$$

Using (3) and (5) to compute the left and right sides of (1) then gives

$$\frac{\partial^2 y}{\partial x^2} = \left(\frac{\partial}{\partial \xi} + \frac{\partial}{\partial \eta}\right)\left(\frac{\partial y}{\partial \xi} + \frac{\partial y}{\partial \eta}\right) = \frac{\partial^2 y}{\partial \xi^2} + 2\frac{\partial^2 y}{\partial \xi \partial \eta} + \frac{\partial^2 y}{\partial \eta^2} \quad (6)$$

$$\frac{\partial^2 y}{\partial t^2} = \left(-c\frac{\partial}{\partial \xi} + c\frac{\partial}{\partial \eta}\right)\left(-c\frac{\partial y}{\partial \xi} + c\frac{\partial y}{\partial \eta}\right)$$

$$= c^2\frac{\partial^2 y}{\partial \xi^2} - 2c^2\frac{\partial^2 y}{\partial \xi \partial \eta} + c^2\frac{\partial^2 y}{\partial \eta^2}. \quad (7)$$

respectively, so plugging in and expanding then gives

$$\frac{\partial^2 y}{\partial \xi \partial \eta} = 0. \quad (8)$$

This partial differential equation has general solution

$$= f(\xi) + g(\eta) \quad (9)$$

$$= f(x - ct) + g(x + ct). \quad (10)$$

where f and g are arbitrary functions, with f representing a right-traveling wave and g a left-traveling wave.

Damped Exponential Cosine Integral

$$\int_0^\infty e^{-wT}\cos(\omega t)d\omega. \qquad (1)$$

Integrate by parts with

$$u \equiv e^{-\omega T} \quad dv = \cos(\omega t)d\omega \qquad (2)$$

$$du \equiv -Te^{-\omega \mathrm{T}}d\omega \quad v = \frac{1}{t}\sin(\omega t), \qquad (3)$$

so

$$\int e^{-\omega T}\cos(\omega t)d\omega = \frac{1}{t}e^{-wt}\sin(\omega t) + \frac{T}{t}\int e^{-wT}\sin(\omega t)d\omega. \qquad (4)$$

Now integrate

$$\int e^{-\omega T}\sin(\omega t)d\omega \qquad (5)$$

by parts. Let

$$u = e^{-\omega T} \quad dv = \sin(\omega t)d\omega \qquad (6)$$

$$du = -Te^{-\omega T}d\omega \quad v = -\frac{1}{t}\cos(\omega t), \qquad (7)$$

so

$$\int e^{-\omega t}\sin(\omega t)d\omega = -\frac{1}{t}\cos(\omega t) - \frac{T}{t}\int e^{-\omega T}\cos(\omega t)d\omega \qquad (8)$$

and

$$\int e^{\omega T}\cos(\omega t)d\omega = \frac{1}{t}e^{-\omega t}\sin(\omega t)$$

$$-\frac{T}{t^2}e^{-\omega t}\cos(\omega t) - \frac{T^2}{t^2}\int e^{-\omega T}\cos(\omega t)d\omega \quad (9)$$

$$\left(1+\frac{T^2}{t^2}\right)\int e^{-\omega T}\cos(\omega t)d\omega$$

$$= e^{-\omega T}\left[\frac{1}{t}\sin(\omega t) - \frac{T}{t^2}\cos(\omega t)\right] \quad (10)$$

$$\frac{t^2+T^2}{t^2}\int e^{-\omega T}\cos(\omega t)d\omega$$

$$= \frac{e^{-\omega t}}{t^2}[t\sin(\omega T) - T\cos(\omega t)] \quad (11)$$

$$\int e^{-\omega T}\cos(\omega t)d\omega$$

$$= \frac{e^{-\omega T}}{t^2+T^2}[t\sin(\omega t) - T\cos(\omega T)]. \quad (12)$$

Therefore,

$$\int_0^\infty e^{-\omega T}\cos(\omega t)d\omega = 0 + \frac{T}{t^2+T^2} = \frac{T}{t^2+T^2}. \quad (13)$$

See also Cosine Integral, Fourier Transform–Lorentzian Function, Lorentzian Function

Damped Simple Harmonic Motion

Adding a damping force proportional to $\dot{x}$ to the equation of simple harmonic motion, the first derivative of x with respect to time, the equation of motion for *damped* simple harmonic motion is

$$\ddot{x} + \beta\dot{x} + \omega_0^2 x = 0, \quad (1)$$

where β is the damping constant. This equation arises, for example, in the analysis of the flow of current in an electronic CLR circuit, (which contains a capacitor, an inductor, and a resistor). The curve produced by two damped harmonic oscillators at right angles to each other is called a harmonograph, and simplifies to a Lissajous curve if $\beta_1 = \beta_2 = 0$.

The damped harmonic oscillator can be solved by looking for trial solutions of the form $x = e^{rt}$. Plugging this into (1) gives

$$(r^2 + \beta r + \omega_0^2)e^{rt} = 0 \quad (2)$$

$$r^2 + \beta r + \omega_0^2 = 0. \quad (3)$$

This is a quadratic equation with solutions

$$r = \frac{1}{2}\left(-\beta \pm \sqrt{\beta^2 - 4\omega_0^2}\right). \quad (4)$$

There are therefore three solution regimes depending on the sign of the quantity inside the square root,

$$\alpha \equiv \beta^2 - 4\omega_0^2. \quad (5)$$

The three regimes are summarized in the following table.

α	regime
$\alpha < 0$	underdamping
$\alpha = 0$	critical damping
$\alpha > 0$	overdamping

If a periodic (sinusoidal) forcing term is added at angular frequency ω, the same three solution regimes are again obtained. Surprisingly, the resulting motion is still periodic (after an initial transient response, corresponding to the solution to the unforced case, has died out), but it has an amplitude different from the forcing amplitude.

The "particular" solution $x_p(t)$ to the forced second-order nonhomogeneous ordinary differential equation

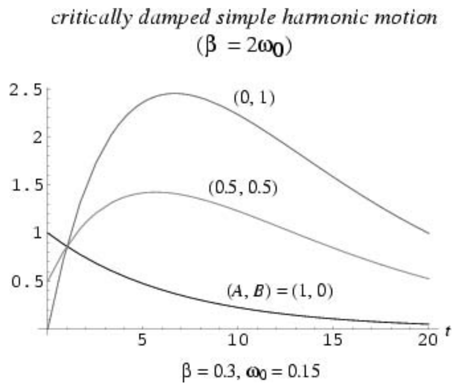
$$\ddot{x} + p(t)\dot{x} + q(t)x = A\cos(\omega t) \quad (6)$$

due to forcing is given by the equation

$$x_p(t) = -x_1(t)\int\frac{x_2(t)g(t)}{W(t)}dt + x_2(t)\int\frac{x_1(t)g(t)}{W(t)}dt, \quad (7)$$

where x_1 and x_2 are the homogeneous solutions to the unforced equation

$$\ddot{x} + p(t)\dot{x} + q(t)x = 0 \quad (8)$$



and $W(t)$ is the Wronskian of these two functions. Once the sinusoidal case of forcing is solved, it can be generalized to *any* periodic function by expressing the periodic function in a Fourier series.

References

Papoulis, A. "Motion of a Harmonically Bound Particle." §15– in *Probability, Random Variables, and Stochastic Processes, 2nd ed.* New York: McGraw-Hill, pp. 524–28, 1984.

Damped Simple Harmonic Motion—Critical Damping

Critical damping is a special case of damped simple harmonic motion in which

$$\alpha \equiv \beta^2 - 4\omega_0^2 = 0, \tag{1}$$

so

$$\beta = 2\omega_0. \tag{2}$$

In this case, $\alpha = 0$ so the solutions OF THE FORM $x = e^{rt}$ satisfy

$$r\pm = \frac{1}{2}(-\beta) = -\frac{1}{2}\beta = -\omega_0. \tag{3}$$

One of the solutions is therefore

$$x_1 = e^{-\omega_0 t}. \tag{4}$$

In order to find the other linearly independent solution, we can make use of the identity

$$x_2(t) = x_1(t)\int \frac{e^{-\int p(t)dt}}{[x_1(t)]^2}\,dt. \tag{5}$$

Since we have $p(t) = 2\omega_0$, $e^{-\int p(t)dt}$ simplifies to $e^{-2\omega_0 t}$. Equation (5) therefore becomes

$$x_2(t) = e^{-\omega_0 t}\int \frac{e^{-2\omega_0 t}}{[e^{-\omega_0 t}]^2}\,dt = e^{-\omega_0 t}\int dt = te^{-\omega_0 t}. \tag{6}$$

The general solution is therefore

$$x = (A + Bt)e^{-\omega_0 t}. \tag{7}$$

In terms of the constants A and B, the initial values are

$$x(0) = A \tag{8}$$

$$x'(0) = B - A\omega, \tag{9}$$

so

$$A = x(0) \tag{10}$$

$$B = x'(0) + \omega_0 x(0). \tag{11}$$

The above plot shows a critically damped simple harmonic oscillator with $\omega = 0.3$, $\beta = 0.15$ for a variety of initial conditions (A, B).
For sinusoidally forced simple harmonic motion with critical damping, the equation of motion is

$$\ddot{x} + 2\omega_0\dot{x} + \omega_0^2 x = A\cos(\omega t), \tag{12}$$

and the WRONSKIAN is

$$W(t) \equiv x_1\dot{x}_2 - \dot{x}_1 x_2 = e^{-2\omega_0 t}. \tag{13}$$

Plugging this into the equation for the particular solution gives

$$x_p(t) = -e^{-\omega_0 t}\int \frac{te^{-\omega_0 t}A\cos(\omega t)}{e^{-2\omega_0 t}}\,dt + te^{-\omega_0 t}\int \frac{e^{-\omega_0 t}A\cos(\omega t)}{e^{-2\omega_0 t}}\,dt$$

$$= \frac{A}{(\omega^2 + \omega_0^2)}\left[\left(\omega_0^2 - \omega^2\right)\cos(\omega t) + 2\omega\omega_0\sin(\omega t)\right]. \tag{14}$$

In order to put this in the desired form, note that we want to equate

$$C\cos\theta + S\sin\theta = Q\cos(\theta + \delta) = Q(\cos\theta\cos\delta - \sin\theta\sin\delta). \tag{15}$$

This means

$$C \equiv Q\cos\delta = \omega_0^2 - \omega^2 \tag{16}$$

$$S \equiv -Q\sin\delta = 2\omega\omega_0, \tag{17}$$

so

$$Q = \sqrt{C^2 + S^2} \tag{18}$$

$$\delta = \tan^{-1}\left(-\frac{S}{C}\right). \tag{19}$$

Plugging in,

$$Q = \sqrt{\omega_0^4 - 2\omega_0^2\omega^2 + \omega^4 + 4\omega_0^2\omega^2} = \omega_0^2\omega^2. \tag{20}$$

$$\delta = \tan^{-1}\left(\frac{2\omega\omega_0}{\omega^2 - \omega_0^2}\right). \tag{21}$$

The solution in the requested form is therefore

$$x_p = \frac{A}{(\omega^2 + \omega_0^2)^2}\left(\omega_0^2 + \omega^2\right)\cos(\omega t + \delta)$$

$$\frac{A}{\omega^2 + \omega_0^2}\cos(\omega t + \delta), \tag{22}$$

where δ is defined by (21).

DAMPED SIMPLE HARMONIC MOTION–UNDERDAMPING, SIMPLE HARMONIC MOTION

References

Papoulis, A. *Probability, Random Variables, and Stochastic Processes, 2nd ed.* New York: McGraw-Hill, p. 528, 1984.

Damped Simple Harmonic Motion—Overdamping

Overdamped simple harmonic motion occurs when

$$\beta^2 - 4\omega_0^2 > 0, \tag{1}$$

so

$$\alpha \equiv \beta^2 - 4\omega_0^2 > 0. \tag{2}$$

$$x_1 = e^{r-t} \tag{3}$$

$$x_2 = e^{r+t}, \tag{4}$$

where

$$r\pm \equiv \frac{1}{2}\left(-\beta \pm \sqrt{\beta^2 - 4\omega_0^2}\right). \tag{5}$$

The general solution is therefore

$$x = Ae^{r-t} + Be^{r+t}, \tag{6}$$

where A and B are constants. The initial values are

$$x(0) = A + B \tag{7}$$

$$x'(0) = Ar_- + Br_+, \tag{8}$$

so

$$A = x(0) + \frac{r_+ x(0) - x'(0)}{r_- - r_+} \tag{9}$$

$$B = -\frac{r_+ x(0) - x'(0)}{r_- - r_+}. \tag{10}$$

The above plot shows an overdamped simple harmonic oscillator with $\omega = 0.3$, $\beta = 0.075$ and three different initial conditions (A, B).

For a cosinusoidally forced overdamped oscillator with forcing function $g(t) = C\cos(\omega t)$, the particular solutions are

$$y_1(t) = e^{r_1 t} \tag{11}$$

$$y_2(t) = e^{r_2 t}, \tag{12}$$

where

$$r_1 \equiv \frac{1}{2}\left(-\beta + \sqrt{\beta^2 - 4\omega_0^2}\right) \tag{13}$$

$$r_2 \equiv \frac{1}{2}\left(-\beta - \sqrt{\beta^2 - 4\omega_0^2}\right). \tag{14}$$

These give the identities

$$r_1 + r_2 = -\beta \tag{15}$$

$$r_1 - r_2 = \sqrt{\beta^2 - 4\omega_0^2} \tag{16}$$

and

$$\omega_0^2 = \frac{1}{4}\left[\beta - (r_1 - r_2)^2\right] = r_1 r_2. \tag{17}$$

The WRONSKIAN is

$$\begin{aligned} W(t) &= y_1 y_2' - y_1' y_2 = e^{r_1 t} r_2 e^{r_2 t} - r_1 e^{r_1 t} e^{r_2 t} \\ &= (r_2 - r_1) e^{(r_1 + r_2)t}. \end{aligned} \tag{18}$$

The particular solution is

$$y_p = -y_1 v_1 + y_2 v_2, \tag{19}$$

where

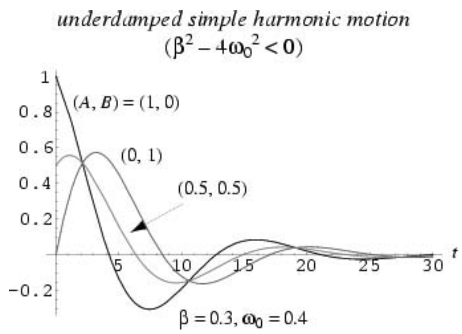
$$v_1 \equiv \int \frac{y_2 g(t)}{W(t)} = \frac{C}{r_2 - r_1} \frac{\omega\sin(\omega t) - r_2\cos(\omega t)}{e^{r_2 t}(r_2^2 + \omega^2)} \tag{20}$$

$$v_2 \equiv \int \frac{y_2 g(t)}{W(t)} = \frac{C}{r_2 - r_1} \frac{\omega\sin(\omega t) - r_1\cos(\omega t)}{e^{r_1 t}(r_2^2 + \omega^2)}. \tag{21}$$

Therefore,

$$\begin{aligned} y_p &= C\frac{\cos(\omega t)(r_1 r_2 - \omega^2) - \sin(\omega t)\omega(r_1 + r_2)}{(r_1^2 + \omega^2)(r_2^2 + \omega^2)} \\ &= \frac{C}{\sqrt{\beta^2\omega^2 + (\omega^2 - \omega_0^2)^2}} \cos(\omega t + \delta), \end{aligned} \tag{22}$$

where



$$\delta = \tan^{-1}\left(\frac{\beta\omega}{\omega^2 - \omega_0^2}\right). \tag{23}$$

Damped Simple Harmonic Motion—Underdamping

Underdamped simple harmonic motion occurs when

$$\beta^2 - 4\omega_0^2 < 0, \tag{1}$$

so

$$\alpha \equiv \beta^2 - 4\omega_0^2 < 0. \tag{2}$$

Define

$$\gamma \equiv \sqrt{-\alpha} = \frac{1}{2}\sqrt{4\omega_0^2 - \beta^2}, \tag{3}$$

then solutions satisfy

$$r\pm = -\frac{1}{2}\beta \pm i\gamma, \tag{4}$$

where

$$r\pm \equiv \frac{1}{2}\left(-\beta \pm \sqrt{\beta^2 - 4\omega_0^2}\right), \tag{5}$$

and are OF THE FORM

$$x = e^{-(\beta/2 \pm i\gamma)t}. \tag{6}$$

Using the EULER FORMULA

$$e^{ix} = \cos x + i \sin x, \tag{7}$$

this can be rewritten

$$x = e^{-(\beta/2)t}[\cos(\gamma t) \pm i \sin(\gamma t)]. \tag{8}$$

We are interested in the *real* solutions. Since we are dealing here with a *linear homogeneous* ODE, linear sums of LINEARLY INDEPENDENT solutions are also solutions. Since we have a sum of such solutions in (8), it follows that the IMAGINARY and REAL PARTS separately satisfy the ODE and are therefore the solutions we seek. The constant in front of the sine term is arbitrary, so we can identify the solutions as

$$x_1 = e^{-(\beta/2)t} \cos(\gamma t) \tag{9}$$

$$x_2 = e^{-(\beta/2)t} \sin(\gamma t), \tag{10}$$

so the general solution is

$$x = e^{-(\beta/2)t}[A \cos(\gamma t) + B \sin(\gamma t)]. \tag{11}$$

The initial values are

$$x(0) = A \tag{12}$$

$$x'(0) = -\frac{1}{2}\beta A + B, \gamma \tag{13}$$

so A and B can be expressed in terms of the initial conditions by

$$A = x(0) \tag{14}$$

$$B = \frac{\beta x(0)}{2\gamma} + \frac{x'(0)}{\gamma}. \tag{15}$$

The above plot shows an underdamped simple harmonic oscillator with $\omega = 0.3$, $\beta = 0.4$ for a variety of initial conditions (A, B).
For a cosinusoidally forced underdamped oscillator with forcing function $g(t) = C \cos(\omega t)$, use

$$\gamma \equiv \frac{1}{2}\sqrt{4\omega_0^2 - \beta^2} \tag{16}$$

$$\alpha \equiv \frac{1}{2}\beta \tag{17}$$

to obtain

$$4\omega_0^2 - \beta^2 = 4\gamma^2 \tag{18}$$

$$\omega_0^2 = \gamma^2 + \frac{1}{4}\beta^2 = \gamma^2 + \alpha^2 \tag{19}$$

$$\beta = 2\alpha. \tag{20}$$

The particular solutions are

$$y_1(t) = e^{-\alpha t} \cos(\gamma t) \tag{21}$$

$$y_2(t) = e^{-\alpha t} \sin(\gamma t). \tag{22}$$

The WRONSKIAN is

$$\begin{aligned} W(t) &\equiv y_1 y_2' - y_1' y_2 \\ &= e^{-\alpha t}\cos(\gamma t)[-\alpha e^{-\alpha t}\sin(\gamma t) + e^{-\alpha t}\gamma\cos(\gamma t)] \\ &\quad -e^{-\alpha t}\sin(\gamma t)[-\alpha e^{-\alpha t}\cos(\gamma t) - e^{-\alpha t}\gamma\sin(\gamma t)] \\ &= e^{-2\alpha t}\{\alpha[-\sin(\gamma t)\cos(\gamma t) + \sin(\gamma t)\cos(\gamma t)] \\ &\quad +\gamma[\cos^2(\gamma t) + \sin^2(\gamma t)]\} \\ &= \gamma e^{-2\alpha t}. \end{aligned} \tag{23}$$

The particular solution is given by

$$y_p = -y_1 v_1 + y_2 v_2, \quad (24)$$

where

$$v_1 = \int \frac{y_2 g(t)}{W(t)} = \frac{C}{\gamma} \int e^{\alpha t} \cos(\gamma t) \cos(\omega t) dt \quad (25)$$

$$v_2 = \int \frac{y_2 g(t)}{W(t)} = \frac{C}{\gamma} \int e^{\alpha t} \cos(\gamma t) \cos(\omega t) dt. \quad (26)$$

Using computer algebra to perform the algebra, the particular solution is

$$y_p(t) = C \frac{(\alpha^2 + \gamma^2 - \omega^2)\cos(\omega t) + 2\alpha\omega \sin(\omega t)}{\left[\alpha^2 + (\gamma - \omega)^2\right]\left[\alpha^2 + (\gamma + \omega)^2\right]}$$

$$= C \frac{\sqrt{(\omega_0^2 - \omega^2)^2 + \beta^2\omega^2}}{(\omega_0^2 - \omega^2)^2 - \omega^2(4\omega_0^2 - \beta^2)} \cos(\omega t + \delta), \quad (27)$$

where

$$\delta = \tan^{-1}\left(\frac{\beta\omega}{\omega^2 - \omega_0^2}\right). \quad (28)$$

If the forcing function is sinusoidal instead of cosinusoidal, then

$$\delta' = \delta - \frac{1}{2}\pi = \tan^{-1} x - \frac{1}{2}\pi = \tan^{-1}\left(-\frac{1}{x}\right), \quad (29)$$

so

$$\delta' = \tan^{-1}\left(\frac{\omega_0^2 - \omega^2}{\beta\omega}\right). \quad (30)$$

d-Analog

N.B. A detailed online essay by S. Finch was the starting point for this entry.

The d-analog of a COMPLEX NUMBER s is defined as

$$[s]_d = 1 - \frac{2^d}{s^d} \quad (1)$$

(Flajolet *et al.* 1995). For integer n, $[2]! \equiv 1$ and

$$[n]_d! = [3][4]\cdots[n]$$

$$= \left(1 - \frac{2^d}{3^d}\right)\left(1 - \frac{2^d}{4^d}\right)\cdots\left(1 - \frac{2^d}{n^d}\right). \quad (2)$$

It can then be extended to complex values via

$$[s]_d! = \prod_{j=1}^{\infty} \frac{[j+2]}{[j+s]} \quad (3)$$

(Flajolet *et al.* 1995). It satisfies the basic functional identity

$$[s]_d! = [s]_d[s-1]_d!. \quad (4)$$

The d-analog of the POLYGAMMA FUNCTION is

$$[\psi]_d(s+1) = \frac{d}{ds} \ln [s]_d!$$

$$= -d \cdot 2^d \sum_{m=1}^{\infty} \frac{1}{(m+s)\left[(m+s)^d - 2^d\right]}. \quad (5)$$

The first few values are

$$[\psi]_1(s) = \frac{3 - 2s}{s^2 - 3s + 2} \quad (6)$$

$$[\psi]_2(s) = \psi_0(s-2) - 2\psi_0(s) + \psi_0(s+2), \quad (7)$$

where $\psi_0(x)$ is the DIGAMMA FUNCTION.

The d-analog of the EULER-MASCHERONI CONSTANT γ is

$$[\gamma]_d = -[\psi]_d(3) = d \cdot 2^d \sum_{m=3}^{\infty} \frac{1}{m(m^d - 2^d)} \quad (8)$$

(Flajolet *et al.* 1995). The first few values are

$$[\gamma]_1 = \frac{3}{2} \quad (9)$$

$$[\gamma]_2 = \frac{11}{12} \quad (10)$$

$$[\gamma]_3 = \frac{9}{2} - H_{3-i\sqrt{3}} - H_{3+i\sqrt{3}} \quad (11)$$

$$[\gamma]_4 = \frac{47}{12} - H_{2-2i} - H_{2+2i}, \quad (12)$$

where H_n is a HARMONIC NUMBER.

The d-analog of the HARMONIC NUMBERS is $[H_2]_d = 0$ and

$$[H_n]_d = d \cdot 2^d \left(\frac{1}{3^{d+1}[3]} + \frac{1}{4^{d+1}[4]} + \ldots + \frac{1}{n^{d+1}[n]}\right) \quad (13)$$

$$= [\psi]_d(n+1) + [\gamma]_d \quad (14)$$

(Flajolet *et al.* 1995).

The d-analog of INFINITY FACTORIAL is given by

$$[\infty!]_d = \prod_{n=3}^{\infty} \left(1 - \frac{2^d}{n^d}\right). \qquad (15)$$

This INFINITE PRODUCT can be evaluated in closed form in terms of π, the HYPERBOLIC SINE $\sinh x$, and GAMMA FUNCTIONS $\Gamma(x)$ involving roots of unity $\zeta_n^k \equiv (-1)^{k/n}$,

$$d_1 = 0 \qquad (16)$$

$$d_2 = \frac{1}{6} \qquad (17)$$

$$d_3 = \frac{\sinh(\pi\sqrt{3})}{42\pi\sqrt{3}} \qquad (18)$$

$$d_4 = \frac{\cosh \pi \sinh \pi}{60\pi} \qquad (19)$$

$$d_5 = \frac{1}{1240\left|\Gamma(2\zeta_5^1)\Gamma(-2\zeta_5^2)\right|^2} \qquad (20)$$

$$d_6 = \frac{\sinh^2(\pi\sqrt{3})}{1512\pi^2} \qquad (21)$$

$$d_7 = \frac{1}{28448\left|\Gamma(2\zeta_7^1)\Gamma(-2\zeta_7^2)\Gamma(2\zeta_7^3)\right|^2} \qquad (22)$$

$$d_8 = \frac{\sinh(2\pi)\left|\sinh(2\zeta_4^1)\right|^2}{16320\pi^3} \qquad (23)$$

$$d_9 = \frac{\sinh(\pi\sqrt{3})}{588672\pi\sqrt{3}\left|\Gamma(2\zeta_9^1)\Gamma(-2\zeta_9^2)\Gamma(-2\zeta_9^4)\right|^2}. \qquad (24)$$

These are all special cases of a general result for INFINITE PRODUCTS.

Dandelin Spheres

The inner and outer SPHERES TANGENT internally to a CONE and also to a PLANE intersecting the CONE are called Dandelin spheres.

The SPHERES can be used to show that the intersection of the PLANE with the CONE is an ELLIPSE. Let π be a PLANE intersecting a right circular CONE with vertex O in the curve E. Call the SPHERES TANGENT to the CONE and the PLANE S_1 and S_2, and the CIRCLES on which the SPHERES are TANGENT to the CONE R_1 and R_2. Pick a line along the CONE which intersects R_1 at Q, E at P, and R_2 at T. Call the points on the PLANE where the CIRCLES are TANGENT F_1 and F_2. Because intersecting tangents have the same length,

$$F_1P = QP$$

$$F_2P = TP.$$

Therefore,

$$PF_1 + PF_2 = QP + PT = QT,$$

which is a constant independent of P, so E is an ELLIPSE with $a = QT/2$.

Danielson-Lanczos Lemma

The DISCRETE FOURIER TRANSFORM of length N (where N is EVEN) can be rewritten as the sum of two DISCRETE FOURIER TRANSFORMS, each of length $N/2$. One is formed from the EVEN-numbered points; the other from the ODD-numbered points. Denote the kth point of the DISCRETE FOURIER TRANSFORM by F_n. Then

$$F_n = \sum_{k=0}^{N-1} f_k e^{-2\pi ink/N}$$
$$= \sum_{k=0}^{N/2-1} e^{-2\pi ikn/(N/2)} f_{2k} + W^n \sum_{k=0}^{N/2-1} e^{-2\pi ikn/(N/2)} f_{2k+1}$$
$$= F_n^e + W_n F_n^o,$$

where $W \equiv e^{-2\pi i/N}$ and $n = 0, \ldots, N$. This procedure can be applied recursively to break up the $N/2$ even and ODD points to their $N/4$ EVEN and ODD points. If N is a POWER of 2, this procedure breaks up the original transform into $1gN$ transforms of length 1. Each transform of an individual point has $F_n^{eeo\cdots} = f_k$ for some k. By reversing the patterns of evens and odds, then letting $e = 0$ and $o = 1$, the value of k in BINARY is produced. This is the basis for the FAST FOURIER TRANSFORM.

Darboux Integral

A variant of the RIEMANN INTEGRAL defined when the UPPER and LOWER INTEGRALS, taken as limits of the LOWER SUM

$$L(f;\phi;N) = \sum_{r=1}^{n} M(f;\delta_r) - \phi(x_{r-1})$$

and UPPER SUM

$$U(f;\phi;N) = \sum_{r=1}^{n} M(f;\delta_r) - \phi(x_{r-1}),$$

are equal. Here, $f(x)$ is a REAL FUNCTION, $\phi(x)$ is a monotonic increasing function with respect to which the sum is taken, $m(f;S)$ denotes the lower bound of $f(x)$ over the interval S, and $M(f;S)$ denotes the upper bound.

See also LOWER INTEGRAL, LOWER SUM, RIEMANN INTEGRAL, UPPER INTEGRAL, UPPER SUM

Darboux Problem

GOURSAT PROBLEM

Darboux Vector

The rotation VECTOR of the TRIHEDRON of a curve with CURVATURE $\kappa \neq 0$ when a point moves along a curve with unit SPEED. It is given by

$$\mathbf{D} = \tau\mathbf{T} + \kappa\mathbf{B}, \quad (1)$$

where τ is the TORSION, $\mathbf{T}$ the TANGENT VECTOR, and $\mathbf{B}$ the BINORMAL VECTOR. The Darboux vector field satisfies

$$\dot{\mathbf{T}} = \mathbf{D} \times \mathbf{T} \quad (2)$$
$$\dot{\mathbf{N}} = \mathbf{D} \times \mathbf{N} \quad (3)$$
$$\dot{\mathbf{B}} = \mathbf{D} \times \mathbf{B}. \quad (4)$$

Darboux's Formula

Darboux's formula is a theorem on the expansion of functions in infinite series. TAYLOR SERIES may be obtained as a special case of the formula, which may be stated as follows.

Let $f(z)$ be analytic at all points of the line joining a to z, and let $\phi(t)$ be any POLYNOMIAL of degree n in t. Then if $0 \leq t \leq 1$, differentiation gives

$$\frac{d}{dt}\sum_{m=1}^{\infty}(-1)^m (z-a)^m B^{(n-m)}(t) f^{(m)}(a+t(a-z))$$
$$= -(z-a)\phi^{(n)}(t) f'(a+t(z-a))$$
$$+(-1)^n (z-a)^{n+1} \phi(t) f^{(n+1)}(a+t(z-a)). \quad (1)$$

But $\phi^{(n)}(t) = \phi^{(n)}(0)$, so integrating t over the interval 0 to 1 gives

$$\phi^{(n)}(0)[f(z)-f(a)]$$
$$= \sum_{m=1}^{n}(-1)^{m-1}(z-a)^m [\phi^{(n-m)}(1) f^{(m)}(z)$$

$$-\phi^{(n-m)}(0)f^{(m)}(a)]$$

$$+(-1)^n(z-a)^{n+1}\int_0^1 \phi(t)f^{(n+1)}(a+t(z-a))dt. \quad (2)$$

The TAYLOR SERIES follows by letting $\phi(t)=(t-1)^n$ and letting $n\to\infty$ (Whittaker and Watson 1990, p. 125).

Darling's Products

A generalization of the HYPERGEOMETRIC FUNCTION identity

$$\begin{aligned}&{}_2F_1(\alpha,\beta;\gamma;z)\,{}_2F_1(1-\alpha,1-\beta;2-\gamma;z)\\&={}_2F_1(\alpha+1-\gamma,\beta+1-\gamma;2-\gamma;z)\,{}_2F_1(\gamma-\alpha,\gamma-\beta;\gamma;z)\end{aligned} \quad (1)$$

to the GENERALIZED HYPERGEOMETRIC FUNCTION ${}_3F_2(a,b,c;d,e;x)$. Darling's products are

$$\begin{aligned}&{}_3F_2\begin{bmatrix}\alpha,\beta,\gamma;z\\ \delta,\varepsilon\end{bmatrix}{}_3F_2\begin{bmatrix}1-\alpha,1-\beta,1-\gamma;z\\ 2-\delta,2-\varepsilon\end{bmatrix}\\
&=\frac{\varepsilon-1}{\varepsilon-\delta}\,{}_3F_2\begin{bmatrix}\alpha+1-\delta,\beta+1-\delta,\gamma+1-\delta;z\\ 2-\delta,\varepsilon+1-\delta\end{bmatrix}\\
&\quad\times{}_3F_2\begin{bmatrix}\delta-\alpha,\delta-\beta,\delta-\gamma;z\\ \delta,\delta+1-\varepsilon\end{bmatrix}\\
&\quad+\frac{\delta-1}{\delta-\varepsilon}\,{}_3F_2\begin{bmatrix}\alpha+1-\varepsilon,\beta+1-\varepsilon,\gamma+1-\varepsilon;z\\ 2-\varepsilon,\delta+1-\varepsilon\end{bmatrix}\\
&\quad\times{}_3F_2\begin{bmatrix}\varepsilon-\alpha,\varepsilon-\beta,\varepsilon-\gamma;z\\ \varepsilon,\varepsilon+1-\delta\end{bmatrix}\end{aligned} \quad (2)$$

and

$$\begin{aligned}&(1-z)^{\alpha+\beta+\gamma-\delta-\varepsilon}\,{}_3F_2\begin{bmatrix}\alpha,\beta,\gamma;z\\ \delta,\varepsilon\end{bmatrix}\\
&=\frac{\varepsilon-1}{\varepsilon-\delta}\,{}_3F_2\begin{bmatrix}\delta-\alpha,\delta-\beta,\delta-\gamma;z\\ \delta,\delta+1-\varepsilon\end{bmatrix}\\
&\quad\times{}_3F_2\begin{bmatrix}\varepsilon-\alpha,\varepsilon-\beta,\varepsilon-\gamma;z\\ \varepsilon-1,\varepsilon+1-\delta\end{bmatrix}\\
&\quad+\frac{\delta-1}{\delta-\varepsilon}\,{}_3F_2\begin{bmatrix}\varepsilon-\alpha,\varepsilon-\beta,\varepsilon-\gamma;z\\ \varepsilon,\varepsilon+1-\delta\end{bmatrix}\\
&\quad\times{}_3F_2\begin{bmatrix}\delta-\alpha,\delta-\beta,\delta-\gamma;z\\ \delta-1,\delta+1-\varepsilon\end{bmatrix},\end{aligned} \quad (3)$$

which reduce to (1) when $\gamma=\varepsilon\to\infty$.

Davenport-Schinzel Sequence

Form a sequence from an ALPHABET of letters $[1, n]$ such that there are no consecutive letters and no alternating subsequences of length greater than d. Then the sequence is a Davenport-Schinzel sequence if it has maximal length $N_d(n)$. The value of $N_1(n)$ is the trivial sequence of 1s: 1, 1, 1, ... (Sloane's A000012). The values of $N_2(n)$ are the POSITIVE INTEGERS 1, 2, 3, 4, ... (Sloane's A000027). The values of $N_3(n)$ are the ODD INTEGERS 1, 3, 5, 7, ... (Sloane's A005408). The first nontrivial Davenport-Schinzel sequence $N_4(n)$ is given by 1, 4, 8, 12, 17, 22, 27, 32, ... (Sloane's A002004). Additional sequences are given by Guy (1994, p. 221) and Sloane.

Dawson's Integral

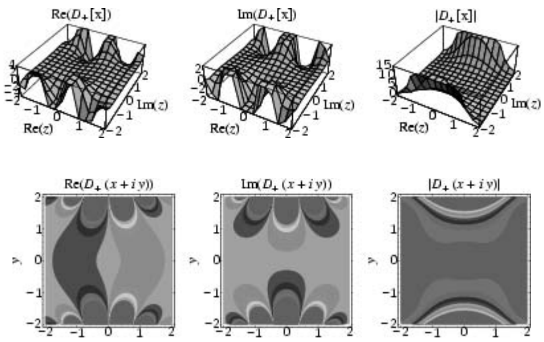
An INTEGRAL which arises in computation of the Voigt lineshape:

$$D(x) \equiv e^{-x^2} \int_0^x e^{y^2}\, dy. \tag{1}$$

It is sometimes generalized such that

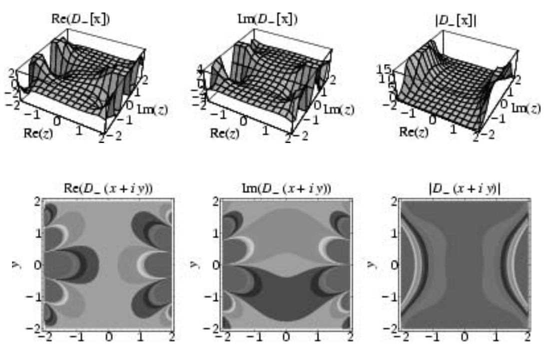
$$D_{\pm}(x) \equiv e^{\mp x^2} \int_0^x e^{\pm y^2}\, dy, \tag{2}$$

giving



$$D_{+}(x) = \frac{1}{2}\sqrt{\pi} e^{-x^2} \operatorname{erfi}(x) \tag{3}$$

$$D_{-}(x) = \frac{1}{2}\sqrt{\pi} e^{x^2} \operatorname{erf}(x), \tag{4}$$



where $\operatorname{erf}(z)$ is the ERF function and $\operatorname{erfi}(z)$ is the imaginary error function ERFI. $D_+(x)$ is illustrated in the left figure above, and $D_-(x)$ in the right figure.

$D_+(x)$ has an ASYMPTOTIC SERIES

$$D_+(x) \sim \frac{1}{2x} + \frac{1}{4x^3} + \dots \tag{5}$$

The plots above show the behavior of $D_+(z)$ in the COMPLEX PLANE.

The plots above show the behavior of $D_-(z)$ in the COMPLEX PLANE.

D_+ has a maximum at $D'_+(x) = 0$, or

$$1 - \sqrt{\pi} e^{-x^2} x^2 \operatorname{erfi}(x) = 0, \tag{6}$$

giving

$$D_+(0.9241388730) = 0.5410442246, \tag{7}$$

and an inflection at $D''_+(x) = 0$, or

$$-2x + \sqrt{\pi} e^{-x^2} \left(2x^2 - 1\right) \operatorname{erfi}(x) = 0, \tag{8}$$

giving

$$D_+(1.5019752683) = 0.4276866160. \tag{9}$$

JACOBI ELLIPTIC FUNCTIONS

de Bruijn Constant

Also called the COPSON-DE BRUIJN CONSTANT. It is the minimal constant

$$c = 1.0164957714\dots$$

such that the inequality

$$\sum_{n=1}^{\infty} a_n \leq c \sum_{n=1}^{\infty} \sqrt{\frac{a_n^2 + a_{n+1}^2 + a_{n+2}^2 + \dots}{n}}$$

always holds.

de Bruijn Diagram

DE BRUIJN GRAPH

de Bruijn Graph

A graph whose nodes are sequences of symbols from some ALPHABET and whose edges indicate the sequences which might overlap.

References

Golomb, S. W. *Shift Register Sequences.* San Francisco, CA: Holden-Day, 1967.

Ralston, A. "de Bruijn Sequences--A Model Example of the Interaction of Discrete Mathematics and Computer Science." *Math. Mag.* **55**, 131–43, 1982.

de Bruijn Sequence

The shortest circular sequence of length σ^a such that every string of length n on the ALPHABET a of size σ occurs as a contiguous subrange of the sequence described by a. A de Bruijn sequence can be generated using `DeBruijnSequence[a, n]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`). For example, a de Bruijn sequence of order n on the alphabet $\{a, b, c\}$ is given by $\{a, a, c, b, b, c, c, a, b\}$.

Every de Bruijn sequence corresponds to an EULERIAN CYCLE on a DE BRUIJN GRAPH. Surprisingly, it turns out that the lexicographic sequence of LYNDON WORDS of lengths DIVISIBLE by n gives the lexicographically smallest de Bruijn sequence (Ruskey).

de Bruijn sequences can be generated by feedback shift registers (Golomb 1966; Ronse 1984; Skiena 1990, p. 196).

de Bruijn-Newman Constant

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let Ξ be the XI FUNCTION defined by

$$\Xi(iz) = \frac{1}{2}\left(z^2 - \frac{1}{4}\right)\pi^{-z/2-\frac{1}{4}}\Gamma\left(\frac{1}{2}z + \frac{1}{4}\right)\zeta\left(z + \frac{1}{2}\right). \quad (1)$$

$\Xi(z/2)/8$ can be viewed as the FOURIER TRANSFORM of the signal

$$\Phi(t) = \sum_{n=1}^{\infty}(2\pi^2 n^4 e^{9t} - 3\pi n^2 e^{5t})e^{-\pi n^2 e^{4t}} \quad (2)$$

for $t \in \mathbb{R} \geq 0$. Then denote the FOURIER TRANSFORM of $\Phi(t)e^{\lambda t^2}$ as $H(\lambda, z)$,

$$\mathcal{F}\left[\Phi(t)e^{\lambda t^2}\right] = H(\lambda, z). \quad (3)$$

de Bruijn (1950) proved that H has only REAL zeros for $\lambda \geq 1/2$. C. M. Newman (1976) proved that there exists a constant Λ such that H has only REAL zeros IFF $\lambda \geq \Lambda$. The best current lower bound (Csordas *et al.* 1993, 1994) is $\Lambda > -5.895 \times 10^{-9}$. The RIEMANN HYPOTHESIS is equivalent to the conjecture that $\Lambda \leq 0$.

de Gua's Theorem

The square of the AREA of the base (i.e., the face opposite the right TRIHEDRAL ANGLE) of a TRIRECTANGULAR TETRAHEDRON is equal to the sum of the squares of the AREAS of its other three faces. This theorem was presented to the Paris Academy of Sciences in 1783 by J. P. de Gua de Malves (1712–785), although it was known to Descartes (1859) and to Faulhaber (Altshiller-Court 1979, p. 300). It is a special case of a general theorem presented by Tinseau to the Paris Academy in 1774 (Osgood and Graustein 1930, p. 517; Altshiller-Court 1979).

de Jonquières Theorem

For an algebraic curve, the total number of groups of a g_N^r consisting in a point of multiplicity k_1, one of multiplicity k_2, ..., one of multiplicity k_p, where

$$\sum k_i = N \quad (1)$$

$$\sum (k_i - 1) = r, \quad (2)$$

and where α_1 points have one multiplicity, α_2 another, etc., and

$$\prod = k_1 k_2 \ldots k_p \quad (3)$$

is

$$\frac{\prod p(p-1)\ldots(p-\rho)}{\alpha_1!\alpha_2!\cdots} \times \left[\frac{\Pi}{p-\rho} - \frac{\sum_i \frac{\partial \Pi}{\partial k_i}}{p-\rho+1} + \frac{\sum_{ij} \frac{\partial^2 \Pi}{\partial k_i \partial k_j}}{p-\rho+2} + \ldots\right]. \quad (4)$$

de Méré's Problem

The probability of getting at least one "6" in four rolls of a single 6-sided DIE is

$$1 - \left(\frac{5}{6}\right)^4 \approx 0.5177, \quad (1)$$

which is slightly higher than the probability of at least one double-six in 24 throws of two dice,

$$1 - \left(\frac{35}{36}\right)^{24} \approx 0.4914. \quad (2)$$

The French nobleman and gambler Chevalier de Méré suspected that (1) was higher than (2), but his mathematical skills were not great enough to demonstrate why this should be so. He posed the question to Pascal, who solved the problem and proved de Méré correct. In fact, de Méré's observation remains true even if two dice are thrown 25 times, since the probability of throwing at least one double-six is then

$$1 - \left(\frac{35}{36}\right)25 \approx 0.5055. \quad (3)$$

de Moivre's Quintic

A QUINTIC EQUATION OF THE FORM

$$x^5 + ax^3 + \frac{1}{5}a^2x + b = 0.$$

See also QUINTIC EQUATION

de Moivre-Laplace Theorem

The asymptotic form of the n-step BERNOULLI DISTRIBUTION with parameters p and $q = 1 - p$ is given by

$$P_n(k) = \binom{n}{k} p^k q^{n-k} \sim \frac{1}{\sqrt{2\pi npq}} e^{-(k-np)^2/(2npq)} \tag{1}$$

(Papoulis 1984, p. 66).

Uspensky (1937) defines the de Moivre-Laplace theorem as the fact that the sum of those terms of the BINOMIAL SERIES of $(p+q)^n$ for which the number of successes x falls between d_1 and d_2 is approximately

$$Q \approx \frac{1}{\sqrt{2\pi}} \int_{t_1}^{t_2} e^{-t^2/2}\,dt, \tag{2}$$

where

$$t_1 \equiv \frac{d_1 - \frac{1}{2} - np}{\sigma} \tag{3}$$

$$t_2 \equiv \frac{d_2 + \frac{1}{2} - np}{\sigma} \tag{4}$$

$$\sigma \equiv \sqrt{npq}. \tag{5}$$

More specifically, Uspensky (1937, p. 129) showed that

$$Q = \frac{1}{\sqrt{2\pi}} \int_{t_1}^{t_2} e^{-t^2/2}\,dt + \frac{q-p}{6\sqrt{2\pi}\sigma}\left[(1-t^2)e^{-t^2/2}\right]_{t_1}^{t_2} + \Omega, \tag{6}$$

where the error term satisfies

$$|\Omega| < \frac{0.13 + 0.18|p-q|}{\sigma^2} + e^{-3\sigma/2} \tag{7}$$

for $\sigma \geq 5$ (Uspensky 1937, p. 129; Kenney and Keeping 1958, pp. 36–7). Note that Kenney and Keeping (1958, p. 37) give the slightly smaller DENOMINATOR $0.12 + 0.18|p - q|$.

A COROLLARY states that the probability that x successes in n trials will differ from the expected value np by more than d is $P\delta = 1 - Q_\delta$, where

$$Q_\delta = \frac{2}{\sqrt{2\pi}} \int_0^\delta e^{-t^2/2}\,dt, \tag{8}$$

with

$$\delta \equiv \frac{d + \frac{1}{2}}{\sigma} \tag{9}$$

(Kenney and Keeping 1958, p. 39). Uspensky (1937, p. 130) showed that $Q_{\delta_1} \equiv P(|x - np| \leq d)$ is given by

$$Q_{\delta_1} = \frac{2}{\sqrt{2\pi}} \int_0^{\delta_1} e^{-u^2/2}\,du + \frac{1 - \theta_1 - \theta_2}{\sqrt{2\pi}\sigma} e^{-\delta_1^2/2} + \Omega_1, \tag{10}$$

where

$$\delta_1 \equiv \frac{d}{\delta} \tag{11}$$

$$\theta_1 \equiv (nq+d) - \lfloor nq+d \rfloor \quad (12)$$

$$\theta_2 \equiv (np+d) - \lfloor np+d \rfloor \quad (13)$$

and the error term satisfies

$$|\Omega_1| < \frac{0.20+0.25|p-q|}{\sigma^2} + e^{-3\sigma/2}, \quad (14)$$

for $\sigma \geq 5$ (Uspensky 1937, p. 130; Kenney and Keeping 1958, pp. 40–1).

de Morgan's and Bertrand's Test

BERTRAND'S TEST

de Morgan's Duality Law

For every proposition involving logical addition and multiplication ("or" and "and"), there is a corresponding proposition in which the words "addition" and "multiplication" are interchanged.

de Morgan's Laws

Let $\cup$ represent "or", $\cap$ represent "and", and $'$ represent "not." Then, for two logical units E and F,

$$(E \cup F)' = E' \cap F'$$

$$(E \cap F)' = E' \cup F'.$$

These laws also apply in the more general context of BOOLEAN ALGEBRA and, in particular, in the BOOLEAN ALGEBRA of SET THEORY, in which case $\cup$ would denote UNION, $\cap$ INTERSECTION, and $'$ complementation with respect to any superset of E and F.

de Polignac's Conjecture

Every EVEN NUMBER is the difference of two consecutive PRIMES in infinitely many ways (Dickson 1952, p. 424). If true, taking the difference 2, this conjecture implies that there are infinitely many TWIN PRIMES (Ball and Coxeter 1987). The CONJECTURE has never been proven true or refuted.

de Rham Cohomology

de Rham cohomology is a formal set-up for the analytic problem: If you have a DIFFERENTIAL K-FORM ω on a MANIFOLD M, is it the EXTERIOR DERIVATIVE of another DIFFERENTIAL K-FORM ω'? Formally, if $\omega = d\omega'$ then $d\omega = 0$.. This is more commonly stated as $d \circ d = 0$, meaning that if ω is to be the EXTERIOR DERIVATIVE of a DIFFERENTIAL K-FORM, a NECESSARY condition that ω must satisfy is that its EXTERIOR DERIVATIVE is zero.

de Rham cohomology gives a formalism that aims to answer the question, "Are all differential k-forms on a MANIFOLD with zero EXTERIOR DERIVATIVE the EXTERIOR DERIVATIVES of $(k-1)$-forms?" In particular, the kth de Rham cohomology vector space is defined to be the space of all k-forms with EXTERIOR DERIVATIVE 0, modulo the space of all boundaries of $(k-1)$-forms. This is the trivial VECTOR SPACE IFF the answer to our question is yes.

The fundamental result about de Rham cohomology is that it is a topological invariant of the MANIFOLD,

namely: the kth de Rham cohomology VECTOR SPACE of a MANIFOLD M is canonically isomorphic to the ALEXANDER-SPANIER COHOMOLOGY VECTOR SPACE $H^k(M;\mathbb{R})$ (also called cohomology with compact support). In the case that M is compact, ALEXANDER-SPANIER COHOMOLOGY is exactly singular cohomology.

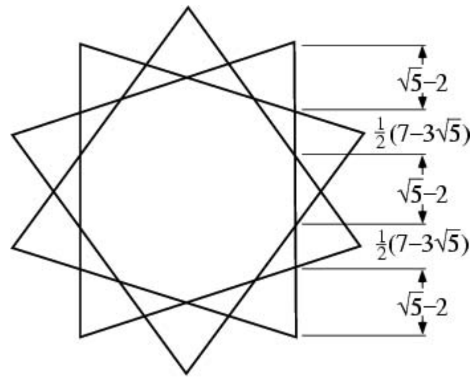
Decagonal Number

A FIGURATE NUMBER OF THE FORM $4n^2-3n$. The first few are 1, 10, 27, 52, 85, ... (Sloane's A001107). The GENERATING FUNCTION giving the decagonal numbers is



$$\frac{x(7x+1)}{(1-x)^3}=x+10x^2+27x^3+52x^4+\ldots$$

The first few odd decagonal numbers are 1, 27, 85, 175, 297, ... (Sloane's A028993), and the first few even decagonal numbers are 10, 52, 126, 232, 360, 540, ... (Sloane's A028994).

Decimal

The BASE-10 notational system for representing REAL NUMBERS. The expression of a number in the decimal system is called its DECIMAL EXPANSION, examples of which are 1, 13, 2028, 12.1, and 3.14159. Each number is called a decimal DIGIT, and the period placed to the right of the units place in a decimal number is called the DECIMAL POINT.

Decimal Comma

The symbol used in continental Europe to denote a DECIMAL POINT, point example 3,14159....

See also DECIMAL POINT

Decimal Expansion

The decimal expansion of a number is its representation in base 10. For example, the decimal expansion of 25^2 is 625, of π is 3.14159..., and of 1/9 is 0.1111....

If $r = p/q$ has a finite decimal expansion, then

$$r = \frac{a_1}{10} + \frac{a_2}{10^2} + \ldots + \frac{a_n}{10^n}$$
$$= \frac{a_1 10^{n-1} + a_2 10^{n-2} + \ldots + a_n}{10^n}$$
$$= \frac{a_1 10^{n-1} + a_2 10^{n-2} + \ldots + a_n}{2^n \cdot 5^n}. \qquad (1)$$

FACTORING possible common multiples gives

$$r = \frac{p}{2^\alpha 5^\beta}, \qquad (2)$$

where $p \not\equiv 0 \pmod{2, 5}$. Therefore, the numbers with finite decimal expansions are fractions of this form. The number of decimals is given by $\max(\alpha, \beta)$ (Wells 1986, p. 60). Numbers which have a finite decimal expansion are called REGULAR NUMBERS.

Any NONREGULAR fraction m/n is periodic, and has a period $\lambda(n)$ independent of m, which is at most $n-1$ DIGITS long. If n is RELATIVELY PRIME to 10, then the period $\lambda(n)$ of m/n is a divisor of $\phi(n)$ and has at most $\phi(n)$ DIGITS, where ϕ is the TOTIENT FUNCTION. It turns out that $\lambda(n)$ is the HAUPT-EXPONENT of 10 (mod n) (Glaisher 1878, Lehmer 1941). When a rational number m/n with $(m, n) = 1$ is expanded, the period begins after s terms and has length t, where s and t are the smallest numbers satisfying

$$10^2 \equiv 10^{s+t} (\text{mod } n). \qquad (3)$$

When $n \not\equiv 0 \pmod{2, 5}$, $s = 0$, and this becomes a purely periodic decimal with

$$10^t \equiv 1 \pmod{n}. \qquad (4)$$

As an example, consider $n = 84$.

$$10^0 \equiv 1 \quad 10^1 \equiv 10 \quad 10^2 \equiv 16 \quad 10^3 \equiv -8$$
$$10^4 \equiv 4 \quad 10^5 \equiv 40 \quad 10^6 \equiv -20 \quad 10^7 \equiv -32,$$
$$10^8 \equiv 16$$

so $s = 2$, $t = 6$. The decimal representation is $1/84 = 0.01\overline{190476}$. When the DENOMINATOR of a fraction m/n has the form $n = n_0 2^\alpha 5^\beta$ with $(n_0, 10) = 1$, then the period begins after $\max(\alpha, \beta)$ terms and the length of the period is the exponent to which 10 belongs (mod n_0), i.e., the number x such that $10^x \equiv 1 (\text{mod} n_0)$. If q is PRIME and $\lambda(q)$ is EVEN, then breaking the repeating DIGITS into two equal halves and adding gives all 9s. For example, $1/7 = 0.\overline{142857}$, and $142 + 857 = 999$. For $1/q$ with a PRIME DENOMINATOR other than 2 or 5, all cycles n/q have the same length (Conway and Guy 1996).

If n is a PRIME and 10 is a PRIMITIVE ROOT of n, then the period $\lambda(n)$ of the repeating decimal $1/n$ is given by

$$\lambda(n) = \phi(n), \qquad (5)$$

where $\phi(n)$ is the TOTIENT FUNCTION. Furthermore, the decimal expansions for p/n, with $p = 1, 2, ..., n-1$ have periods of length $n-1$ and differ only by a cyclic permutation. Such numbers are called LONG PRIMES by conway and guy (1996). an equivalent definition is that

$$10^i \equiv 1 (\text{mod} n) \qquad (6)$$

for $i = n-1$ and no i less than this. In other words, a NECESSARY (but not SUFFICIENT) condition is that the number $9R_{n-1}$ (where R_n is a REPUNIT) is DIVISIBLE by n, which means that R_n is DIVISIBLE by n.

The first few numbers with maximal decimal expansions, called FULL REPTEND PRIMES, are 7, 17, 19, 23, 29, 47, 59, 61, 97, 109, 113, 131, 149, 167, ... (Sloane's A001913). The decimals corresponding to these are called CYCLIC NUMBERS. No general method is known for finding FULL REPTEND PRIMES. Artin conjectured that ARTIN'S CONSTANT $C = 0.3739558136\ldots$ is the fraction of PRIMES p for with $1/p$ has decimal maximal period (Conway and Guy 1996). D. Lehmer has generalized this conjecture to other bases, obtaining values which are small rational multiples of C.

To find DENOMINATORS with short periods, note that

$$10^1 - 1 = 3^2$$
$$10^2 - 1 = 3^2 \cdot 11$$

$$10^3 - 1 = 3^3 \cdot 37$$

$$10^4 - 1 = 3^2 \cdot 11 \cdot 101$$

$$10^5 - 1 = 3^2 \cdot 41 \cdot 271$$

$$10^6 - 1 = 3^3 \cdot 7 \cdot 11 \cdot 13 \cdot 37$$

$$10^7 - 1 = 3^2 \cdot 239 \cdot 4649$$

$$10^8 - 1 = 3^2 \cdot 11 \cdot 73 \cdot 101 \cdot 137$$

$$10^9 - 1 = 3^4 \cdot 37 \cdot 333667$$

$$10^{10} - 1 = 3^2 \cdot 11 \cdot 41 \cdot 271 \cdot 9091$$

$$10^{11} - 1 = 3^2 \cdot 21649 \cdot 513239$$

$$10^{12} - 1 = 3^3 \cdot 7 \cdot 11 \cdot 13 \cdot 37 \cdot 101 \cdot 9901.$$

The period of a fraction with DENOMINATOR equal to a PRIME FACTOR above is therefore the POWER of 10 in which the factor first appears. For example, 37 appears in the factorization of $10^3 - 1$ and $10^9 - 1$, so its period is 3. Multiplication of any FACTOR by a $2^\alpha 5^\beta$ still gives the same period as the FACTOR alone. A DENOMINATOR obtained by a multiplication of two FACTORS has a period equal to the first POWER of 10 in which both FACTORS appear. The following table gives the PRIMES having small periods (Sloane's A046106, A046107, and A046108; Ogilvy and Anderson 1988).

period	primes
1	3
2	11
3	37
4	101
5	41, 271
6	7, 13
7	239, 4649
8	73, 137
9	333667
10	9091
11	21649, 513239
12	9901
13	53, 79, 265371653
14	909091
15	31, 2906161
16	17, 5882353
17	2071723, 5363222357
18	19, 52579
19	1111111111111111111
20	3541, 27961

A table of the periods e of small PRIMES other than the special $p = 5$, for which the decimal expansion is not periodic, follows (Sloane's A002371).

p	e	p	e	p	e
3	1	31	15	67	33
7	6	37	3	71	35
11	2	41	5	73	8
13	6	43	21	79	13
17	16	47	46	83	41
19	18	53	13	89	44
23	22	59	58	97	96
29	28	61	60	101	4

Shanks (1873ab) computed the periods for all PRIMES up to 120,000 and published those up to 29,989.

Decimal Period

DECIMAL COMMA, DECIMAL EXPANSION, DECIMAL POINT

Decimal Point

The symbol uses to separate the integer part of a decimal number from its fractional part is called the decimal point. In the United States, the decimal point is denoted with a period (e.g., 3.1415), whereas a raised period is used in Britain (e.g., 3.1415), and a DECIMAL COMMA is used in continental Europe (e.g., 3,1415). The number 3.1415 is voiced "three point one four one five," while in continental Europe, 3,1415 would be voiced "three comma one four one five."

See also COMMA, DECIMAL, DECIMAL COMMA, DECIMAL EXPANSION

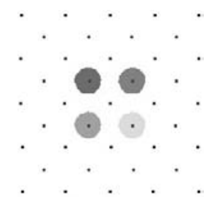
Decision Problem

Does there exist an ALGORITHM for deciding whether or not a specific mathematical assertion does or does not have a proof? The decision problem is also known as the ENTSCHEIDUNGSPROBLEM (which, not so coincidentally, is German for "decision problem"rpar;. Using the concept of the TURING MACHINE, Turing showed the answer to be NEGATIVE for elementary NUMBER THEORY. J. Robinson and Tarski showed the decision problem is undecidable for arbitrary FIELDS.

Decision Theory

A branch of GAME THEORY dealing with strategies to maximize the outcome of a given process in the face of uncertain conditions.

See also NEWCOMB'S PARADOX, OPERATIONS RESEARCH, PRISONER'S DILEMMA



Deck Transformation

The deck transformations of a UNIVERSAL COVER $\tilde{X}$ form a group Γ, which is the FUNDAMENTAL GROUP of the QUOTIENT SPACE

$$X = \tilde{X}/\Gamma.$$

Deck transformations are also called covering transformations, and are defined for any COVER $p : A \to X$. They act on A by homeomorphisms which preserve the projection p.

The UNIVERSAL COVER of X, denoted $\tilde{X}$, is a SIMPLY CONNECTED space and is a COVERING of $\pi : \tilde{X} \to X$. Every loop in X, say a function f on the unit interval with $f(0) = f(1) = p$, lifts to a path $\tilde{f} \in \tilde{X}$, which only depends on the choice of $\tilde{f} \in \pi^{-1}(p)$, i.e., the starting point in the PREIMAGE of π. Moreover, the endpoint $\tilde{f}(1)$ depends only on the HOMOTOPY CLASS of f and $\tilde{f}(0)$. Given a point $q \in \tilde{X}$, and α, a member of the FUNDAMENTAL GROUP of X, a point $\alpha \cdot q$ is defined to be the endpoint of a LIFT of a path f which represents α.

For example, when X is the SQUARE TORUS then $\tilde{X}$ is the plane and the preimage $\pi^{-1}(p)$ is a translation of the integer lattice $\{(n, m)\} \subset \mathbb{R}^2$. Any loop in the torus lifts to a path in the plane, with the endpoints lying in the integer lattice. These translated integer lattices are the ORBITS of the action of $\mathbb{Z} \times \mathbb{Z}$ on $\mathbb{R}^2$ by addition. The above animation shows the action of some deck transformations on some disks in the plane. The spaces are the torus and its UNIVERSAL COVER, the plane. An element of the fundamental group, shown as the path in blue, defines a deck transformation of the universal cover. It moves around the points in the universal cover. The points moved to have the same projection in the torus. The blue path is a loop in the torus, and all of its preimages are shown.

Decomposable

A DIFFERENTIAL K-FORM ω of degree p in an EXTERIOR ALGEBRA $\wedge V$ is decomposable if there exist p ONE-FORMS α_i such that

$$\omega = \alpha_1 \wedge \ldots \wedge \alpha_{pi}, \qquad (1)$$

where $\alpha \wedge \beta$ denotes a WEDGE PRODUCT. Forms of degree 0, 1, $\dim V - 1$, and $\dim V$ are always decomposable. Hence the first instance of indecomposable forms occurs in $\mathbb{R}^4$, in which case $e_1 \wedge e_2 + e_3 \wedge e_4$ is indecomposable.

If a p-form ω has an ENVELOPE of dimension p then it is decomposable. In fact, the ONE-FORMS in the (dual) basis to the envelope can be used as the α_i above.

The PLÜCKER RELATIONS form a system of quadratic equations on the a_I in

$$\omega = \sum a_I e_{i_1} \wedge \ldots \wedge e_{i_p}, \qquad (2)$$

which is equivalent to ω being decomposable. Since a decomposable p-form corresponds to a p-dimensional subspace, these quadratic equations show that the GRASSMANNIAN is a PROJECTIVE VARIETY. In particular, ω is decomposable if for every $\beta \in \wedge^{p+1} V^*$,

$$i(i(\beta)\omega)\omega = 0, \qquad (3)$$

where i denotes CONTRACTION and V^* is the DUAL SPACE to V.

Here is a *Mathematica* function which tests whether the ANTISYMMETRIC TENSOR w is decomposable.

```
< <DiscreteMath‘Combinatorica‘;
ContractAll[a_List, b_List] :=   Module[{k =
TensorRank[a] - TensorRank[b]},   If[k >= 0,
Map[Flatten[#1].Flatten[b]   &,   a,   {k}],
ContractAll[b, a]
    ]
   ]  Envelope[a_List?VectorQ] := Select[{a},
#1    !=     Table[0,    {Length[a]}]     &]
Envelope[a_List] := Module[
    {
     z, inds, vects,
    d = Dimensions[a][[1]], r = TensorRank[a]
    },
   z = Table[0, ##1] & @@ Table[{d}, {r - 1}];
    inds = KSubsets[Range[d], r - 1];
    vects = Map[ContractAll[a, ReplacePart[z,
1, #1]] &, inds];
     Select[RowReduce[vects], #1 != Table[0,
{d}] &]
      ]         DecomposableQ[a_?ListQ]    :=
(Length[Envelope[a]] == TensorRank[a])
```

Decreasing Function

A function $f(x)$ decreases on an INTERVAL I if $f(b) < f(a)$ for all $b > a$, where $a, b \in I$. Conversely, a function $f(x)$ increases on an INTERVAL I if $f(b) > f(a)$ for all $b > a$ with $a, b \in I$.

If the DERIVATIVE $f'(x)$ of a CONTINUOUS FUNCTION $f(x)$ satisfies $f'(x) < 0$ on an OPEN INTERVAL (a, b), then $f(x)$ is decreasing on (a, b). However, a function may decrease on an interval without having a derivative defined at all points. For example, the function $-x^{1/3}$ is decreasing everywhere, including the origin $x = 0$, despite the fact that the DERIVATIVE is not defined at that point.

Dedekind Eta

DEDEKIND ETA FUNCTION

Dedekind Eta Function

Let

$$q = e^{2\pi i\tau}, \tag{1}$$

then the Dedekind eta function is defined over the UPPER HALF-PLANE $H = \{\tau : \Im[\tau] > 0\}$ by

$$\eta(\tau) \equiv q^{1/24} \prod_{n=1}^{\infty} (1 - q^n) = (q; q)_\infty, \tag{2}$$

which can be written as

$$\eta(\tau) = q^{1/24} \left\{ 1 + \sum_{n=1}^{\infty} (-1)^n \left[q^{n(3n-1)/2} + q^{n(3n+1)/2} \right] \right\} \tag{3}$$

(Weber 1902, pp. 85 and 112; Atkin and Morain 1993). $\eta(\tau)$ is a MODULAR FORM first introduced by Dedekind in 1877, and is related to the MODULAR DISCRIMINANT of the WEIERSTRASS ELLIPTIC FUNCTION by

$$\Delta(\tau) = (2\pi)^{12} [\eta(\pi)]^{24} \tag{4}$$

(Apostol 1997, p. 47).
The derivative of $\eta(t)$ satisfies

$$-4\pi i \frac{d}{d\tau} \ln[\eta(\tau)] = G_2(\tau) \tag{5}$$

$$\frac{d}{d\tau} \ln\left[-\frac{1}{\tau}\right] = \frac{d}{d\tau} \ln[\eta(\tau)] + \frac{1}{2} \frac{d}{dr} \ln(-i\tau), \tag{6}$$

where $G_2(\tau)$ is an EISENSTEIN SERIES.

Letting $\zeta_{24} = e^{2\pi i/24} = e^{\pi i/12}$ be a ROOT OF UNITY, $\eta(\tau)$ satisfies

$$\eta(\tau + 1) = e^{\pi i/12} \eta(\tau) \tag{7}$$

$$\eta(\tau + n) = e^{\pi i n/12} \eta(\tau) \tag{8}$$

$$\eta\left(-\frac{1}{\tau}\right) = \sqrt{-i\tau}\, \eta(\tau) \tag{9}$$

where n is an integer (Weber 1902, p. 113; Atkin and Morain 1993; Apostol 1997, p. 47). The Dedekind eta function is related to the JACOBI THETA FUNCTION ϑ_3 by

$$\vartheta_3(0, e^{\pi i\tau}) = \frac{\eta^2\left(\frac{1}{2}(\tau + 1)\right)}{\eta(\tau + 1)} \tag{10}$$

(Apostol 1997, p. 91).

Macdonald (1972) has related most expansions OF THE FORM $(q, q)_\infty^c$ to affine ROOT SYSTEMS. Exceptions not included in Macdonald's treatment include $c = 2$, found by Hecke and Rogers, $c = 4$, found by Ramanujan , and $c = 26$, found by Atkin (Leininger and Milne 1997). Using the Dedekind eta function, the JACOBI TRIPLE PRODUCT identity is written

$$(q, q)_\infty^3 = \sum_{n=0}^{\infty} (-1)^n (2n + 1) q^{n(n+1)/2} \tag{11}$$

(Jacobi 1829, Hardy and Wright 1979, Leininger and Milne 1997, Hirschhorn 1999).

Dedekind's functional equation states that if $\left[\begin{smallmatrix} ab \\ cd \end{smallmatrix}\right] \in \Gamma$, where Γ is the MODULAR GROUP GAMMA, $c > 0$, and $\tau \in H$, then

$$\eta\left(\frac{a\tau+b}{c\tau+d}\right)=\epsilon(a,b,c,d)\left[-i\sqrt{c\tau+d}\right]\eta(\tau), \quad (12)$$

where

$$\epsilon(a,b,c,d)=\exp\left[\pi i\left(\frac{a+d}{12c}+s(-d,c)\right)\right], \quad (13)$$

and

$$s(h,k)=\sum_{r=1}^{k-1}\frac{r}{k}\left(\frac{hr}{k}-\left[\frac{hr}{k}\right]-\frac{1}{2}\right) \quad (14)$$

is a DEDEKIND SUM (Apostol 1997, pp. 52–7), with $\lfloor x\rfloor$ the FLOOR FUNCTION.

Dedekind Section

DEDEKIND CUT

Dedekind Sum

Given RELATIVELY PRIME INTEGERS p and q (i.e., $(p,q)=1$), the Dedekind sum is defined by

$$s(p,q)\equiv\sum_{i=1}^{q}\left(\left(\frac{i}{q}\right)\right)\left(\left(\frac{pi}{q}\right)\right), \quad (1)$$

where

$$((x))\equiv\begin{cases}x-\lfloor x\rfloor-\frac{1}{2} & x\notin\mathbb{Z}\\ 0 & x\in\mathbb{Z},\end{cases} \quad (2)$$

with $\lfloor x\rfloor$ the FLOOR FUNCTION. $((x))$ is an ODD FUNCTION since $((x))=-((x))$ and is periodic with period 1. The Dedekind sum is meaningful even if $(p,q)\neq 1$, so the relatively prime restriction is sometimes dropped (Apostol 1997, p. 72). The symbol $s(p,q)$ is sometimes used instead of $s(p,a)$ (Beck 2000).

The Dedekind sum can also be expressed in the form

$$s(p,q)=\frac{1}{4q}\sum_{r=1}^{q-1}\cot\left(\frac{\pi pr}{k}\right)\cot\left(\frac{\pi r}{q}\right). \quad (3)$$

If $0<h<k$, let $r_0, r_1, ..., r_{n+1}$ denote the remainders in the EUCLIDEAN ALGORITHM given by

$$r_0=k \quad (4)$$

$$r_1=h \quad (5)$$

$$r_{j+1} \equiv r_{j-1} \pmod{r_j} \tag{6}$$

for $1 \le r_{j+1} < r_j$ and $r_{n+1} = 1$. Then

$$s(h,k) = \frac{1}{12} \sum_{j=1}^{n+1} \left\{ (-1)^{j+1} \frac{r_j^2 + r_{j-1}^2 + 1}{r_j r_{j-1}} \right\} - \frac{(-1)^n + 1}{8} \tag{7}$$

(Apostol 1997, pp. 72–3).

In general, there is no simple formula for closed-form evaluation of $s(p,q)$, but some special cases are

$$s(1,q) = \frac{(q-1)(q-2)}{12q} \tag{8}$$

$$s(2, q \text{ odd}) = \frac{(q-1)(q-2)}{24q} \tag{9}$$

(Apostol 1997, p. 62). Apostol (1997, p. 73) gives the additional special cases

$$12hks(h,k) = (k-1)(k-h^2-1) \quad \text{for } k \equiv 1 \pmod{h} \tag{10}$$

$$12hks(h,k) = (k-2)\left[k - \frac{1}{2}(h^2+1)\right] \quad \text{for } k \equiv 2 \pmod{h} \tag{11}$$

$$12hks(h,k) = k^2 + (h^2 - 6h + 2)k + h^2 + 1 \quad \text{for } k \equiv -1 \pmod{h} \tag{12}$$

$$12hks(h,k) = k^2 - \frac{h^2 - t(r-1)(r-2)h + r^2 + 1}{r} k + h^2 + 1 \tag{13}$$

for $k \equiv r \pmod{h}$ and $h \equiv t \pmod{r}$, where $r \ge 1$ and $t = \pm 1$. Finally,

$$12hks(h,k) = k^2 - \frac{h^2 + 4r(t-2)(t+2)h + 26}{5} k + h^2 + 1 \tag{14}$$

for $k \equiv 5 \pmod{h}$ and $h \equiv t \pmod{5}$, where $t = \pm 1$ or ± 2.

Dedekind sums obey 2-term

$$s(p,q) + s(q,p) = -\frac{1}{4} + \frac{1}{12}\left(\frac{p}{q} + \frac{q}{p} + \frac{1}{pq}\right) \tag{15}$$

(Dedekind 1953; Rademacher and Grosswald 1972; Pommersheim 1993; Apostol 1997, pp. 62–4) and 3-term

$$s(bc',a) + s(ca',b) + s(ab',c) = -\frac{1}{4} + \frac{1}{12}\left(\frac{a}{bc} + \frac{b}{ca} + \frac{c}{ab}\right) \tag{16}$$

(Rademacher 1954), reciprocity laws, where a, a'; b, b'; and c, c' are pairwise COPRIME, and

$$aa' \equiv 1 \pmod{b} \tag{17}$$

$$bb' \equiv 1 \pmod{c} \tag{18}$$

$$cc' \equiv 1 \pmod{a} \tag{19}$$

(Pommersheim 1993).

$6ps(p,q)$ is an integer, and if $\theta = (3,q)$, then

$$12pqs(p,q) \equiv 0 \pmod{\theta p} \tag{20}$$

and

$$12pqs(q,p) \equiv q^2 + 1 \pmod{\theta p}. \tag{21}$$

In addition, $s(p,q)$ satisfies the congruence

$$12qs(p,q) \equiv (q-1)(q+2) - 4p(q-1) + 4 \sum_{r<q/2} \left\lfloor \frac{2pr}{q} \right\rfloor \pmod{8}, \tag{22}$$

which, if q is odd, becomes

$$12qs(p,q) \equiv q - 1 + 4 \sum_{r<q/2} \left\lfloor \frac{2pr}{q} \right\rfloor \pmod{8} \tag{23}$$

(Apostol 1997, pp. 65–6). If $q = 3$, 5, 7, or 13, let $r = 24/(q-1)$, let integers a, b, c, d be given with $ad - bc = 1$ such that $c = c_1 q$ and $c_1 > 0$, and let

$$\delta = \left\{ s(a,c) - \frac{a+d}{12c} \right\} - \left\{ s(a_1, c_1) - \frac{a+d}{12c_1} \right\}. \tag{24}$$

Then $r\delta$ is an even integer (Apostol 1997, pp. 66–9).

Let p, q, u, $v \in \mathbb{N}$ with $(p,q) = (u,v) = 1$ (i.e., are pairwise RELATIVELY PRIME), then the Dedekind sums also satisfy

$$s(p,q) + s(u,v) = s(pu' - qv', pv + qu) - \frac{1}{4} + \frac{1}{12}\left(\frac{q}{vt} + \frac{v}{tq} + \frac{t}{qv}\right), \tag{25}$$

where $t = pv + qu$, and u', v' are any INTEGERS such that $uu' + vv' = 1$ (Pommersheim 1993).

If p is prime, then

$$(p+1)s(h,k) = s(ph,k) + \sum_{m=0}^{p-1} s(h + mk, pk) \tag{26}$$

(Dedekind 1953; Apostol 1997, p. 73). Moreover, it has been beautifully generalized by Knopp (1980).

Dedekind's Axiom

For every partition of all the points on a line into two nonempty SETS such that no point of either lies between two points of the other, there is a point of one SET which lies between every other point of that SET and every point of the other SET.

Dedekind's Problem

The determination of the number of monotone BOOLEAN FUNCTIONS of n variables (equivalent to the number of ANTICHAINS on the n-set $\{1, 2, ..., n\}$) is called Dedekind's problem.

See also ANTICHAIN, BOOLEAN FUNCTION

Deducible

If q is logically deducible from p, this is written $p \vdash q$.

Deep Theorem

Qualitatively, a deep theorem is a theorem whose proof is long, complicated, difficult, or appears to involve branches of mathematics which are not obviously related to the theorem itself (Shanks 1993). Shanks (1993) cites the QUADRATIC RECIPROCITY THEOREM as an example of a deep theorem.

See also THEOREM, TRIVIAL

Defective Matrix

A MATRIX whose EIGENVECTORS are not COMPLETE.

Defective Number

DEFICIENT NUMBER

Deficiency

Given BINOMIAL COEFFICIENT $\binom{N}{k}$, write

$$N - k + i = a_i b_i,$$

for $1 \le i \le k$, where b_i contains only those prime factors $> k$. Then the number of i for which $b_i = 1$ (i.e., for which all the factors of $N - k + i$ are $\le k$ is called the deficiency of $\binom{N}{k}$ (Erdos*et al.* 1993, Guy 1994). The following table gives the GOOD BINOMIAL COEFFICIENTS (i.e., those with $1\,\mathrm{pf}\binom{N}{k} > k$)) having deficiency $d \ge 1$ (Erdos *et al.* 1993), and Erdos *et al.* (1993) conjecture that there are no other with $d > 1$.

d	Good Binomial Coefficients
1	$\binom{3}{2}, \binom{7}{3}, \binom{13}{4}, \binom{14}{4}, \binom{23}{5}, \binom{62}{6}, \binom{89}{8}, \ldots$
2	$\binom{7}{4}, \binom{44}{8}, \binom{74}{10}, \binom{174}{12}, \binom{239}{14}, \binom{5179}{27}, \binom{8413}{28}, \binom{96622}{42}$
3	$\binom{46}{10}, \binom{47}{10}, \binom{241}{16}, \binom{2105}{25}, \binom{1119}{27}, \binom{6459}{33}$
4	$\binom{47}{11}$
9	$\binom{284}{28}$

See also ABUNDANCE, GOOD BINOMIAL COEFFICIENT

Deficient Number

Numbers which are not PERFECT and for which

$$s(N) \equiv \sigma(N) - N < N,$$

or equivalently

$$\sigma(n) < 2n,$$

where $\sigma(N)$ is the DIVISOR FUNCTION. Deficient numbers are sometimes called DEFECTIVE NUMBERS (Singh 1997). PRIMES, PRIME POWERS, and any divisors of a PERFECT or deficient number are all deficient. The first few deficient numbers are 1, 2, 3, 4, 5, 7, 8, 9, 10, 11, 13, 14, 15, 16, 17, 19, 21, 22, 23, ... (Sloane's A005100).

Definable Set

An ANALYTIC, BOREL, or COANALYTIC SET.

Defined

If A and B are equal by definition (i.e., A is defined as B), then this is written symbolically as $A \equiv B$, $A := B$, or sometimes $\doteq$.

Definite Integral

An INTEGRAL

$$\int_a^b f(x)dx$$

with upper and lower limits. The first FUNDAMENTAL THEOREM OF CALCULUS allows definite integrals to be computed in terms of INDEFINITE INTEGRALS, since if F is the INDEFINITE INTEGRAL for $f(x)$, then

$$\int_a^b f(x)dx = F(b) - F(a).$$

See also CALCULUS, FUNDAMENTAL THEOREMS OF CALCULUS, INDEFINITE INTEGRAL, INTEGRAL

Degen's Eight-Square Identity

See also EULER FOUR-SQUARE IDENTITY, FIBONACCI IDENTITY

Degeneracy

The property of being DEGENERATE.

See also DEGENERATE

Degenerate

A limiting case in which a class of object changes its nature so as to belong to another, usually simpler, class. For example, the POINT is a degenerate case of the CIRCLE as the RADIUS approaches 0, and the CIRCLE is a degenerate form of an ELLIPSE as the ECCENTRICITY approaches 0. Another example is the two identical ROOTS of the second-order POLYNOMIAL $(x-1)^2$. Since the n ROOTS of an nth degree POLYNOMIAL are usually distinct, ROOTS which coincide are said to be degenerate. Degenerate cases often require special treatment in numerical and analytical solutions. For example, a simple search for both ROOTS of the above equation would find only a single one: 1.

The word degenerate also has several very specific and technical meanings in different branches of mathematics.

See also TRIVIAL

References

Arfken, G. *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 513–14, 1985.

Degree

The word "degree" has many meanings in mathematics.

The most common meaning is the unit of ANGLE measure defined such that an entire rotation is $360°$. This unit harks back to the Babylonians, who used a base 60 number system. $360°$ likely arises from the Babylonian year, which was composed of 360 days (12 months of 30 days each). The degree is subdivided into 60 MINUTES per degree, and 60 SECONDS per MINUTE.

The word "degree" is also used in many contexts where it is synonymous with "order," as applied for example to polynomials.

See also ARC MINUTE, ARC SECOND, DEGREE (EXTENSION FIELD), DEGREE OF FREEDOM, DEGREE (MAP), DEGREE (POLYNOMIAL), DEGREE (VERTEX), INDEGREE, LOCAL DEGREE, OUTDEGREE

References

Bringhurst, R. *The Elements of Typographic Style, 2nd ed.* Point Roberts, WA: Hartley and Marks, p. 276, 1997.

Degree (Algebraic Surface)

ORDER (ALGEBRAIC SURFACE)

Degree (Extension Field)

The degree (or relative degree, or index) of an EXTENSION FIELD K/F, denoted $[K:F]$, is the dimension of K as a VECTOR SPACE over F, i.e.,

$$[K:F] = \dim_F K.$$

If $[K:F]$ is finite, then the extension is said to be finite; otherwise, it is said to be infinite.

See also EXTENSION FIELD

References

Dummit, D. S. and Foote, R. M. *Abstract Algebra, 2nd ed.* Englewood Cliffs, NJ: Prentice-Hall, p. 424, 1998.

Degree (Map)

Let $f: M \mapsto N$ be a MAP between two compact, connected, oriented n-D MANIFOLDS without boundary. Then f induces a HOMOMORPHISM f_* from the HOMOLOGY GROUPS $H_n(M)$ to $H_n(N)$, both canonically isomorphic to the INTEGERS, and so f_* can be thought of as a HOMOMORPHISM of the INTEGERS. The INTEGER $d(f)$ to which the number 1 gets sent is called the degree of the MAP f.

There is an easy way to compute $d(f)$ if the MANIFOLDS involved are smooth. Let $x \in \mathbb{N}$, and approximate f by a smooth map HOMOTOPIC to f such that x is a "regular value" of f (which exist and are everywhere by SARD'S THEOREM). By the IMPLICIT FUNCTION THEOREM, each point in $f^{-1}(x)$ has a NEIGHBORHOOD such that f restricted to it is a DIFFEOMORPHISM. If the DIFFEOMORPHISM is orientation preserving, assign it the number $+1$, and if it is orientation reversing, assign it the number -1. Add up all the numbers for all the points in $f^{-1}(x)$, and that is the $d(f)$, the degree of f. One reason why the degree of a map is important is because it is a HOMOTOPY invariant. A sharper result states that two self-maps of the n-sphere are homotopic IFF they have the same degree. This is equivalent to the result that the nth HOMOTOPY GROUP of the n-SPHERE is the set $\mathbb{Z}$ of INTEGERS. The ISOMORPHISM is given by taking the degree of any representation.

One important application of the degree concept is that homotopy classes of maps from n-spheres to n-spheres are classified by their degree (there is exactly one homotopy class of maps for every INTEGER n, and n is the degree of those maps).

Degree (Polynomial)

The highest POWER in a UNIVARIATE POLYNOMIAL is known as its degree, or sometimes "order." For example, the POLYNOMIAL

$$P(x) = a_n x^n + \ldots + a_2 x^2 + a_1 x + a_0$$

is of degree n, denoted $P(x) = n$. The degree of a polynomial is implemented in *Mathematica* as `Exponent[`*poly*`, x]`.

See also ORDER (POLYNOMIAL)

Degree (Vertex)

VERTEX DEGREE

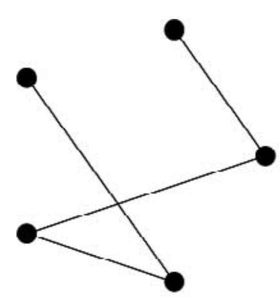
Degree Matrix

A DIAGONAL MATRIX corresponding to a GRAPH that has the VERTEX DEGREE of v_i in the ith position (Skiena 1990, p. 235).

See also VERTEX DEGREE

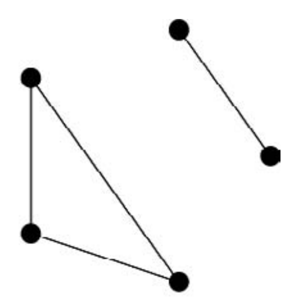
References

Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, 1990.



Degree of Freedom

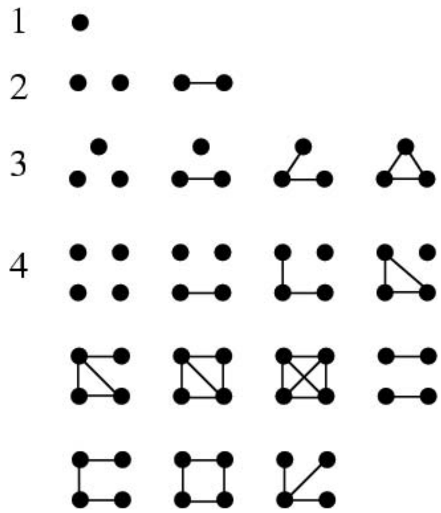
The number of degrees of freedom in a problem, distribution, etc., is the number of parameters which may be independently varied.



See also LIKELIHOOD RATIO

Degree Sequence

Given an UNDIRECTED GRAPH, a degree sequence is a monotonic nonincreasing sequence of the VERTEX DEGREES (valencies) of its VERTICES. The number of degree sequences for a graph of a given order is closely related to GRAPHICAL PARTITIONS. The minimum vertex degree in a GRAPH G is denoted $\delta(G)$, and the maximum degree is denoted $\Delta(G)$ (Skiena 1990, p. 157). A GRAPH whose degree sequence contains multiple copies of a single integer is called a REGULAR GRAPH. A graph corresponding to a given degree sequence can be constructed using `RealizeDegreeSequence[`*d*`]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).



82, 2, 2, 1, 1<

82, 2, 2, 1, 1<

It is possible for two topologically distinct graphs to have the same DEGREE SEQUENCE.

The number of distinct degree sequences for graphs of $n = 1, 2, \ldots$ nodes are given by 1, 2, 4, 11, 31, 102, 342, ... (Sloane's A004251), compared with the total number of nonisomorphic simple undirected graphs with n NODES of 1, 2, 4, 11, 34, 156, 1044, ... (Sloane's A000088). The first order having fewer degree sequences than number of nonisomorphic graphs is therefore $n = 5$. For the graphs illustrated above, the degree sequences are given in the following table.

1	$\{0\}$
2	$\{0, 0\}$, $\{1, 1\}$
3	$\{0, 0, 0\}$, $\{1, 1, 0\}$, $\{2, 1, 1\}$, $\{2, 2, 2\}$
4	$\{0, 0, 0, 0\}$, $\{1, 1, 0, 0\}$, $\{2, 1, 1, 0\}$, $\{2, 2, 2, 0\}$, $\{3, 2, 2, 1\}$, $\{3, 3, 2, 2\}$, $\{3, 3, 3, 3\}$, $\{1, 1, 1, 1\}$, $\{2, 2, 1, 1\}$, $\{2, 2, 2, 2\}$, $\{3, 1, 1, 1\}$

The possible sums of elements for a degree sequence of order n are 0, 2, 4, 6, ..., $n(n-1)$.

A degree sequence is said to be k-connected if there exists some k-CONNECTED GRAPH corresponding to the degree sequence. For example, while the degree sequence $\{1, 2, 1\}$ is 1- but not 2-connected, $\{2, 2, 2\}$ is 2-connected.

See also DEGREE SET, DEGREE (VERTEX), GRAPHIC SEQUENCE, GRAPHICAL PARTITION, k-CONNECTED GRAPH, REGULAR GRAPH

Dehn Invariant

An invariant defined using the angles of a 3-D POLYHEDRON. It remains constant under solid DISSECTION and reassembly. Solids with the same VOLUME can have different Dehn invariants.

Two POLYHEDRA can be dissected into each other only if they have the same volume and the same Dehn invariant. In 1902, Dehn showed that two interdissectable polyhedra must have equal Dehn invariants, settling the third of HILBERT'S PROBLEMS, and Sydler (1965) showed that two polyhedra with the same Dehn invariants are interdissectable.

Dehn Surgery

The operation of drilling a TUBULAR NEIGHBORHOOD of a KNOT K in $\mathbb{S}^3$ and then gluing in a solid TORUS so that its meridian curve goes to a (p, q)-curve on the TORUS boundary of the KNOT exterior. Every compact connected 3-MANIFOLD comes from Dehn surgery on a LINK in $\mathbb{S}^3$.

Dehn's Lemma

An embedding of a 1-SPHERE in a 3-MANIFOLD which exists continuously over the 2-DISK also extends over the DISK as an embedding. This theorem was proposed by Dehn in 1910, but a correct proof was not obtained until the work of Papakyriakopoulos (1957ab).

Del

GRADIENT

Del Bar Operator

The operator $\bar{\partial}$ is defined on a COMPLEX MANIFOLD, and is called the 'del bar operator.' The EXTERIOR DERIVATIVE d takes a function and yields a ONE-FORM. It decomposes as

$$d = \partial + \bar{\partial}, \quad (1)$$

as complex ONE-FORMS decompose into TYPE

$$\Lambda^1 = \Lambda^{1,0} \otimes \Lambda^{0,1} \quad (2)$$

where $\otimes$ denotes the DIRECT SUM. More concretely, in coordinates $z_k = x_k + iy_k$,

$$\partial f = \sum \left(\frac{\partial f}{\partial x_k} - i \frac{\partial f}{\partial y_k} \right) dz_k \quad (3)$$

and

$$\bar{\partial} f = \sum \left(\frac{\partial f}{\partial x_k} + i \frac{\partial f}{\partial y_k} \right) d\bar{z}_k. \quad (4)$$

These operators extend naturally to forms of higher degree. In general, if α is a (p, q)-FORM, then $\partial\alpha$ is a $(p+1, q)$-form and $\bar{\partial}\alpha$ is a $(p, q+1)$-form. The equation $\bar{\partial} f = 0$ expresses the condition of f being a HOLOMORPHIC FUNCTION. More generally, a $(p, 0)$-FORM α is called HOLOMORPHIC if $\bar{\partial}\alpha = 0$, in which case its coefficients, as written in a COORDINATE CHART, are HOLOMORPHIC FUNCTIONS.

The del bar operator is also well-defined on SECTIONS of a HOLOMORPHIC VECTOR BUNDLE. The reason is because a change in coordinates or trivializations is HOLOMORPHIC.

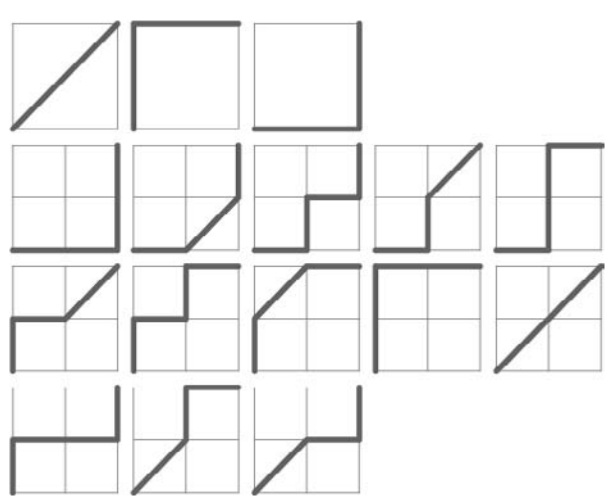
Delambre's Analogies

GAUSS'S FORMULAS

Delannoy Number



The Delannoy numbers are the number of lattice paths from $(0, 0)$ to (b, a) in which only east $(1, 0)$, north $(0, 1)$, and northeast $(1, 1)$ steps are allowed (i.e, $\rightarrow$, $\uparrow$, and $\nearrow$). They are given by the RECURRENCE RELATION

$$D(a, b) = D(a-1, b) + D(a, b-1) + D(a-1, b-1), \quad (1)$$

with $D(0, 0) = 1$. They have the GENERATING FUNCTION

$$\sum_{p,q=1}^{\infty} D(p, q) x^p y^q = (1 - x - y - xy)^{-1} \quad (2)$$

(Comtet 1974, p. 81).

For $n \equiv a = b$, the Delannoy numbers are the number of "king walks"

$$D(n, n) = P_n(3),$$

where $P_n(x)$ is a LEGENDRE POLYNOMIAL (Moser 1955; Comtet 1974, p. 81; Vardi 1991). Another expression is

$$D(n, n) = \sum_{k=0}^{n} \binom{n}{k} \binom{n+k}{k} = 2F_1(-n, n+1; 1, -1), \quad (3)$$

where $\binom{a}{b}$ is a BINOMIAL COEFFICIENT and $2F_1(a, b; c; z)$ is a HYPERGEOMETRIC FUNCTION. The values of $D(n, n)$ for $n = 1$, 2, ... are 3, 13, 63, 321, 1683, 8989, 48639, ... (Sloane's A001850).

The SCHRÖDER NUMBERS bear the same relation to the Delannoy numbers as the CATALAN NUMBERS do to the BINOMIAL COEFFICIENTS.

See also BINOMIAL COEFFICIENT, CATALAN NUMBER, MOTZKIN NUMBER, SCHRÖDER NUMBER

Delaunay Triangulation

Delaunay triangulation *Voronoi diagram* *Delaunay and Voronoi*

The Delaunay triangulation is a TRIANGULATION which is equivalent to the NERVE of the cells in a VORONOI DIAGRAM, i.e., that triangulation of the CONVEX HULL of the points in the diagram in which every CIRCUMCIRCLE of a TRIANGLE is an empty circle (Okabe *et al.* 1992, p. 94). The *Mathematica* command `PlanarGraphPlot[pts]` in the *Mathematica* add-on package `DiscreteMath'Computational-Geometry'` (which can be loaded with the command `<<DiscreteMath'`) plots the Delaunay triangulation of the given list of points.

The Delaunay triangulation and VORONOI DIAGRAM in $\mathbb{R}^2$ are dual to each other.

See also TRIANGULATION, VORONOI DIAGRAM

Delian Problem

CUBE DUPLICATION, DELIAN CONSTANT

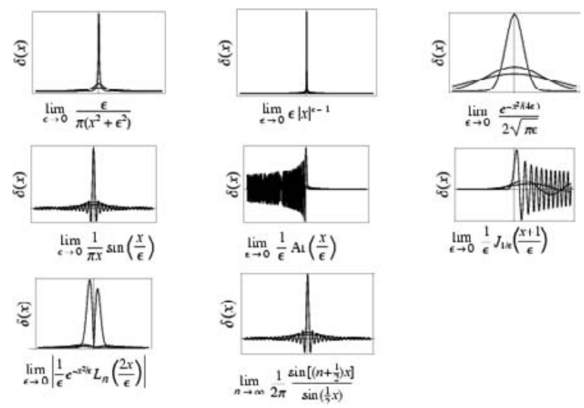
Delta Amplitude

Given an AMPLITUDE ϕ and a MODULUS m in an ELLIPTIC INTEGRAL,

$$\Delta(\phi) \equiv \sqrt{1 - m \sin^2\phi}.$$

See also AMPLITUDE, ELLIPTIC INTEGRAL, MODULUS (ELLIPTIC INTEGRAL)

Delta Curve



A curve which can be turned continuously inside an EQUILATERAL TRIANGLE. There are an infinite number of delta curves, but the simplest are the CIRCLE and lens-shaped Δ-biangle. All the Δ curves of height h have the same PERIMETER $2\pi h/3$. Also, at each position of a Δ curve turning in an EQUILATERAL TRIANGLE, the perpendiculars to the sides at the points of contact are CONCURRENT at the instantaneous center of rotation.

Delta Function

A generalized function which can be defined as the limit of a class of delta sequences. The delta function is sometimes called "Dirac's delta function" or the "impulse symbol" (Bracewell 1999). Formally, δ is a linear functional from a space (commonly taken as a Schwarz space S or the space of all smooth functions of compact support D) of test functions f. The action of δ on f, commonly denoted $\delta[f]$ or $\langle\delta, f\rangle$, then gives the value at 0 of f for any function f.

In engineering contexts, the functional nature of the delta function is often suppressed, and δ is instead viewed as a "special kind" of function, resulting in the useful (but unfortunately deceptive) notation $\delta(x)$. In addition, it is possible to define the delta function as an integral satisfying certain properties at infinity (although this is often not explicitly stated), and commonly used (equivalent) definitions of this type include

$$\delta(x) = \frac{1}{\pi}\lim_{\epsilon\to 0}\frac{\epsilon}{x^2+\epsilon^2}, \tag{1}$$

$$= \lim_{\epsilon\to 0}\epsilon|x|^{\epsilon-1} \tag{2}$$

$$= \lim_{\epsilon\to 0^+}\frac{1}{2\sqrt{\pi\epsilon}}e^{-x^2/(4\epsilon)} \tag{3}$$

$$= \lim_{\epsilon\to 0}\frac{1}{\pi x}\sin\left(\frac{x}{\epsilon}\right) \tag{4}$$

$$= \lim_{\epsilon\to 0}\frac{1}{\epsilon}\mathrm{Ai}\left(\frac{x}{\epsilon}\right) \tag{5}$$

$$= \lim_{\epsilon\to 0}\frac{1}{\epsilon}J_{1/\epsilon}\left(\frac{x+1}{\epsilon}\right) \tag{6}$$

$$= \lim_{\epsilon\to 0}\left|\frac{1}{\epsilon}e^{-x^2/\epsilon}L_n\left(\frac{2x}{\epsilon}\right)\right| \tag{7}$$

$$= \lim_{n\to\infty}\frac{1}{2\pi}\frac{\sin\left[\left(n+\frac{1}{2}\right)x\right]}{\sin\left(\frac{1}{2}x\right)}. \tag{8}$$

Here, $\mathrm{Ai}(x)$ is an Airy function, $J_n(x)$ is a Bessel function of the first kind, and $L_n(x)$ is a Laguerre polynomial of arbitrary positive integer order. (8) is sometimes called the Dirichlet kernel.

The fundamental equation that defines derivatives of the delta function $\delta(x)$ is

$$\int f(x)\delta^{(n)}(x)\,dx \equiv -\int\frac{\partial f}{\partial x}\delta^{(n-1)}(x)\,dx. \tag{9}$$

Letting $f(x) = xg(x)$ in this definition, it follows that

$$\int xg(x)\delta'(x)dx = -\int\delta(x)\frac{\partial}{\partial x}[xg(x)]dx,$$

$$= -\int\delta(x)[g(x)+xg'(x)]dx$$

$$= -\int g(x)\delta(x)dx, \tag{10}$$

where the second term can be dropped since $\int xg'(x)\delta(x)dx = 0$, so (10) implies

$$x\delta'(x) = -\delta(x). \tag{11}$$

In general, the same procedure gives

$$\int[x^n f(x)]\delta^{(n)}(x)dx = (-1)^n\int\frac{\partial^n[x^n f(x)]}{\partial x^n}\delta(x)dx, \tag{12}$$

but since any power of x times $\delta(x)$ integrates to 0, it follows that only the constant term contributes. Therefore, all terms multiplied by derivatives of $f(x)$ vanish, leaving $n!f(x)$, so

$$\int[x^n f(x)]\delta^{(n)}(x)dx = (-1)^n n!\int f(x)\delta(x)dx, \tag{13}$$

which implies

$$x^n\delta^{(n)}(x) = (-1)^n n!\delta(x). \tag{14}$$

Other identities involving the derivative of the delta function include

$$\delta'(-x) = -\delta'(x) \tag{15}$$

$$\int_{-\infty}^{\infty} f(x)\delta'(x-a)dx = -f'(a) \tag{16}$$

$$(\delta' * f)(a) = \int_{-\infty}^{\infty} \delta'(a-x) f(x)\,dx = f'(a) \tag{17}$$

where $*$ denotes CONVOLUTION,

$$\int_{-\infty}^{\infty} |\delta'(x)|\,dx = \infty, \tag{18}$$

and

$$x^2 \delta'(x) = 0. \tag{19}$$

The delta function can also be viewed as the DERIVATIVE of the HEAVISIDE STEP FUNCTION,

$$\frac{d}{dx}[H(x)] = \delta(x) \tag{20}$$

(Bracewell 1999, p. 94).

Additional identities include

$$\delta(x-a) = 0 \tag{21}$$

for $x \neq a$,

$$\int_{a-\varepsilon}^{a+\varepsilon} \delta(x-a)\,dx = 1, \tag{22}$$

where ε is any POSITIVE number, and

$$\int_{-\infty}^{\infty} f(x)\delta(x-a)\,dx = f(a) \tag{23}$$

$$\delta(ax) = \frac{1}{|a|}\delta(x) \tag{24}$$

$$\delta(x^2 - a^2) = \frac{1}{2|a|}[\delta(x+a) + \delta(x-a)] \tag{25}$$

More generally, the delta function of a function is given by

$$\delta[g(x)] = \sum_i \frac{\delta(x - x_i)}{|g'(x_i)|}, \tag{26}$$

where the x_is are the ROOTS of g. For example, examine

$$\delta(x^2 + x - 2) = \delta[(x-1)(x+2)]. \tag{27}$$

Then $g'(x) = 2x + 1$, so $g'(x_1) = g'(1) = 3$ and $g'(x_2) = g'(-2) = -3$, and we have

$$\delta(x^2 + x - 2) = \frac{1}{3}\delta(x-1) + \frac{1}{3}\delta(x+2). \tag{28}$$

A FOURIER SERIES expansion of $\delta(x-a)$ gives

$$a_n = \frac{1}{\pi}\int_{-\pi}^{\pi} \delta(x-a)\cos(nx)\,dx = \frac{1}{\pi}\cos(na) \tag{29}$$

$$b_n = \frac{1}{\pi}\int_{-\pi}^{\pi} \delta(x-a)\sin(nx)\,dx = \frac{1}{\pi}\sin(na), \tag{30}$$

so

$$\begin{aligned}\delta(x-a) &= \frac{1}{2\pi} + \frac{1}{\pi} \\ &\quad \times \sum_{n=1}^{\infty}[\cos(na)\cos(nx) + \sin(na)\sin(nx)] \\ &= \frac{1}{2\pi} + \frac{1}{\pi}\sum_{n=1}^{\infty}\cos[n(x-a)].\end{aligned} \tag{31}$$

The delta function is given as a FOURIER TRANSFORM as

$$\delta(x) = \mathscr{F}[1] = \int_{-\infty}^{\infty} e^{-2\pi ikx}\,dk. \tag{32}$$

Similarly,

$$\mathscr{F}^{-1}[\delta(x)] = \int_{-\infty}^{\infty} \delta(x) e^{2\pi ikx}\,dx = 1 \tag{33}$$

(Bracewell 1999, p. 95). More generally, the FOURIER TRANSFORM of the delta function is

$$\mathscr{F}[\delta(x-x_0)] = \int_{-\infty}^{\infty} e^{-2\pi ikx}\delta(x-x_0)\,dx = e^{2\pi ikx_0}. \tag{34}$$

Delta functions can also be defined in 2-D, so that in 2-D CARTESIAN COORDINATES

$$\delta^2(x,y) = \begin{cases} 0 & x^2 + y^2 \neq 0 \\ \infty & x^2 + y^2 = 0, \end{cases} \tag{35}$$

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \delta^2(x,y)\,dx\,dy = 1 \tag{36}$$

$$\delta^2(ax, by) = \frac{1}{|ab|}\delta^2(x,y), \tag{37}$$

and

$$\delta^2(x,y) = \delta(x)\delta(y). \tag{38}$$

Similarly, in POLAR COORDINATES,

$$\delta^2(x,y) = \frac{\delta(r)}{\pi|r|} \tag{39}$$

(Bracewell 1999, p. 85).

In 3-D CARTESIAN COORDINATES

$$\delta^3(x,y,z) = \delta^3(\mathbf{x}) = \begin{cases} 0 & x^2 + y^2 + z^2 \neq 0 \\ \infty & x^2 + y^2 + z^2 = 0 \end{cases} \tag{40}$$

$$\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \delta^3(x,y,z)\,dx\,dy\,dz = 1 \tag{41}$$

and

$$\delta(x)\delta(y)\delta(z). \tag{42}$$

in CYLINDRICAL COORDINATES (r, θ, z),

$$\delta^3(r,\theta,z)=\frac{\delta(r)\delta(z)}{\pi r}. \quad (43)$$

In SPHERICAL COORDINATES (r, θ, ϕ),

$$\delta^3(r,\theta,\phi)=\frac{\delta(r)}{2\pi r^2} \quad (44)$$

(Bracewell 1999, p. 85).

A series expansion in CYLINDRICAL COORDINATES gives

$$\delta^3(\mathbf{r}_1-\mathbf{r}_2)=\frac{1}{r_1}\delta(r_1-r_2)\delta(\theta_1-\theta_2)\delta(z_1-z_2)$$

$$=\frac{1}{r_1}\delta(r_1-r_2)\frac{1}{2\pi}\sum_{m=-\infty}^{\infty}e^{im(\theta_1-\theta_2)}\frac{1}{2\pi}\int_{-\infty}^{\infty}e^{ik(z_1-z_2)}dk. \quad (45)$$

The delta function also obeys the so-called SIFTING PROPERTY

$$\int f(x)\delta(x-x_0)dx=f(x_0) \quad (46)$$

(Bracewell 1999, pp. 74–5).

$$=\frac{1}{\pi x}\,\frac{e^{inx}-e^{-inx}}{2i} \quad (5)$$

$$=\frac{1}{2\pi ix}\,[e^{ixt}]_{-n}^{n} \quad (6)$$

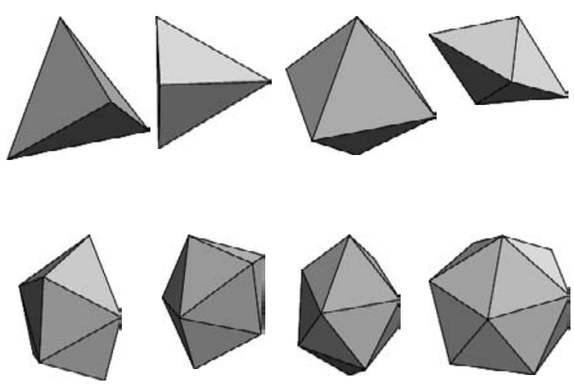
$$=\frac{1}{2\pi}\int_{-n}^{n}e^{ixt}\,dt \quad (7)$$

$$=\frac{1}{2\pi}\,\frac{\sin[(n+\frac{1}{2})x]}{\sin(\frac{1}{2}x)}, \quad (8)$$

where (8) is known as the DIRICHLET KERNEL.

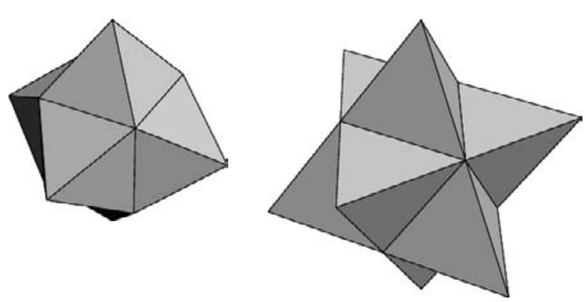
See also DELTA FUNCTION

Delta Variation



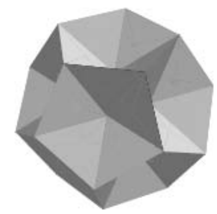
VARIATION

Deltahedron



A POLYHEDRON whose faces are CONGRUENT EQUILATERAL TRIANGLES (Wells 1986, p. 73). There are an infinite number of deltahedra, but only eight convex ones (Freudenthal and van der Waerden 1947).

Among this list of eight, faces composed of coplanar equilateral triangles sharing an edge (such as the RHOMBIC DODECAHEDRON) are not allowed. The eight convex deltahedra have $n = 4$, 6, 8, 10, 12, 14, 16, and 20 faces. These are summarized in the table below, and illustrated in the following figures.



n	Name
4	TETRAHEDRON
6	TRIANGULAR DIPYRAMID
8	OCTAHEDRON
10	PENTAGONAL DIPYRAMID
12	SNUB DISPHENOID
14	TRIAUGMENTED TRIANGULAR PRISM
16	GYROELONGATED SQUARE DIPYRAMID
20	ICOSAHEDRON

The 24-faced deltahedra formed by (1) CUMULATION of the CUBE and (2) STELLA OCTANGULA are both concave.

The "caved in" CUMULATED DODECAHEDRON is a deltahedron with 60 faces. It is ICOSAHEDRON STELLATION I_{20} (Wells 1991, p. 78).

Cundy (1952) identified 17 concave deltahedra with two kinds of VERTICES.

See also CUMULATION, GYROELONGATED SQUARE DIPYRAMID, ICOSAHEDRON, OCTAHEDRON, PENTAGONAL DIPYRAMID, SNUB DISPHENOID TETRAHEDRON, TRIANGULAR DIPYRAMID, TRIAUGMENTED TRIANGULAR PRISM

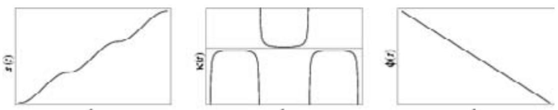
Deltohedron

TRAPEZOHEDRON

Deltoid



A 3-cusped HYPOCYCLOID, also called a tricuspoid. The deltoid was first considered by Euler in 1745 in connection with an optical problem. It was also investigated by Steiner in 1856 and is sometimes

called Steiner's hypocycloid (Lockwood 1967; Coxeter and Greitzer 1967, p. 44; MacTutor Archive). The equation of the deltoid is obtained by setting $n \equiv a/b = 3$ in the equation of the HYPOCYCLOID, where a is the RADIUS of the large fixed CIRCLE and b is the RADIUS of the small rolling CIRCLE, yielding the parametric equations

$$x = \left[\frac{2}{3}\cos\phi - \frac{1}{3}\cos(2\phi)\right]a = 2b\cos\phi + b\cos(2\phi) \quad (1)$$

$$y = \left[\frac{2}{3}\sin\phi + \frac{1}{3}\sin(2\phi)\right]a = 2b\sin\phi - b\sin(2\phi). \quad (2)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s(t) = 4\int_0^t |\sin\left(\frac{3}{2}t'\right)dt' = \frac{16}{3}\sin^2\left(\frac{3}{4}t\right) \quad (3)$$

$$\kappa(t) = -\frac{1}{8}\csc\left(\frac{3}{2}t\right) \quad (4)$$

$$\phi(t) = -\frac{1}{2}t. \quad (5)$$

As usual, care must be taken in the evaluation of $s(t)$ for $t > 2\pi/3$. Since the form given above comes from an integral involving the ABSOLUTE VALUE of a function, it must be monotonic increasing. Each branch can be treated correctly by defining

$$n = \left[\frac{3t}{2\pi}\right] + 1, \quad (6)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, giving the formula

$$s(t) = (-1)^{1+[n \pmod 2]}\frac{16}{3}\sin^2\left(\frac{3}{4}t\right) + \frac{32}{3}\left[\frac{1}{2}n\right]. \quad (7)$$

The total ARC LENGTH is computed from the general HYPOCYCLOID equation

$$s_n = \frac{8a(n-1)}{n}. \quad (8)$$

With $n = 3$, this gives

$$s_3 = \frac{16}{3}a. \quad (9)$$

The AREA is given by

$$A_n = \frac{(n-a)(n-2)}{n^2}\pi a^2 \quad (10)$$

with $n = 3$

$$A_3 = \frac{2}{9}\pi a^2. \quad (11)$$

The length of the tangent to the tricuspoid, measured between the two points P, Q in which it cuts the curve again, is constant and equal to $4a$. If you draw TANGENTS at P and Q, they are at RIGHT ANGLES.

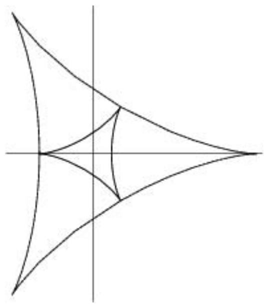
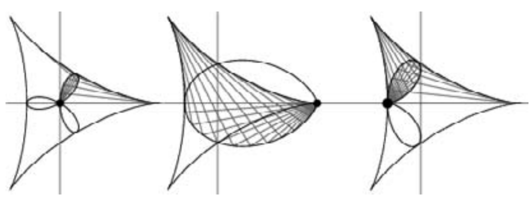
Deltoid Caustic

The caustic of the DELTOID when the rays are PARALLEL in any direction is an ASTROID.



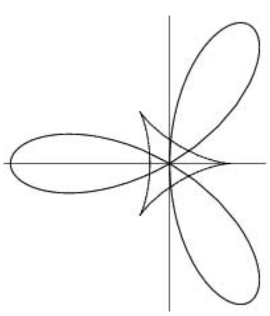
Deltoid Evolute

A HYPOCYCLOID EVOLUTE for $n = 3$ is another DEL-



TOID scaled by a factor $n/(n-2)=3/1=3$ and rotated $1/(2\cdot 3)=1/6$ of a turn.

Deltoid Involute

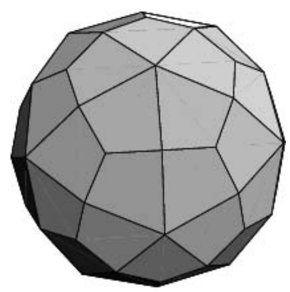


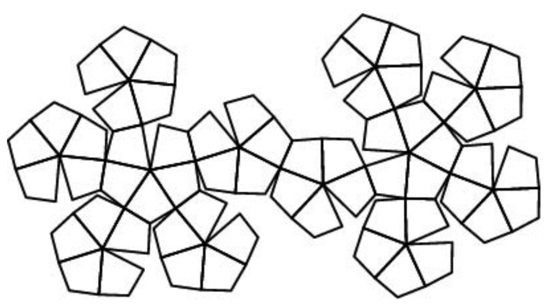
A HYPOCYCLOID INVOLUTE for $n=3$ is another DELTOID scaled by a factor $(n-2)/n=1/3$ and rotated $1/(2\cdot 3)=1/6$ of a turn.

Deltoid Pedal Curve

The PEDAL CURVE for a DELTOID with the PEDAL POINT at the CUSP is a FOLIUM. For the PEDAL POINT at the CUSP (NEGATIVE x-intercept), it is a BIFOLIUM. At the center, or anywhere on the inscribed EQUILATERAL TRIANGLE, it is a TRIFOLIUM.

Deltoid Radial Curve



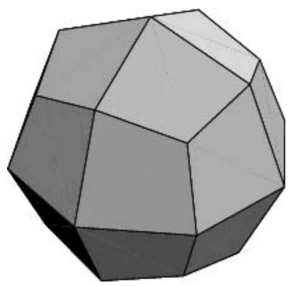


The TRIFOLIUM

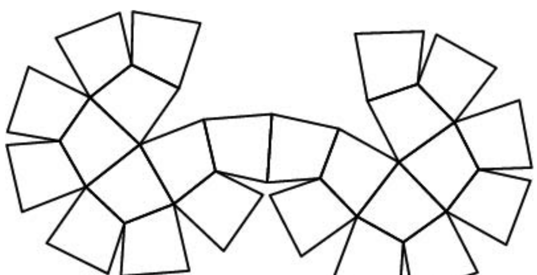
$$x = x_0 + 4a\cos\phi - 4a\cos(2\phi)$$

$$y = y_0 + 4a\sin\phi + 4a\sin(2\phi).$$

Deltoidal Hexecontahedron



The 60-faced DUAL POLYHEDRON of the SMALL RHOMBICOSIDODECAHEDRON A_5 and Wenninger dual W_{14}. It is sometimes also called the trapezoidal hexecontahedron or strombic hexecontahedron.



See also ARCHIMEDEAN DUAL, ARCHIMEDEAN SOLID, HEXECONTAHEDRON, SMALL RHOMBICOSIDODECAHEDRON

References

Wenninger, M. J. *Dual Models.* Cambridge, England: Cambridge University Press, p. 24, 1983.

Deltoidal Icositetrahedron

The 24-faced DUAL POLYHEDRON of the SMALL RHOMBICUBOCTAHEDRON A_6 and Wenninger dual W_{13}. It is also called the TRAPEZOIDAL ICOSITETRAHEDRON. For a SMALL RHOMBICUBOCTAHEDRON with unit edge length, the deltoidal icositetrahedron has edge lengths

$$s_1 = \frac{2}{7}\sqrt{10-\sqrt{2}} \tag{1}$$

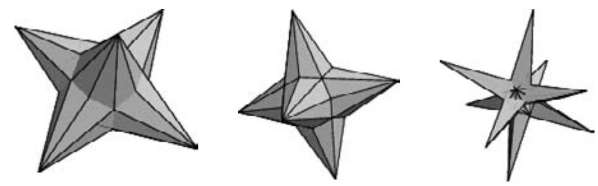
$$s^2 = \sqrt{4-2\sqrt{2}} \tag{2}$$

and INRADIUS

$$r = \sqrt{\frac{2}{17}\left(7+4\sqrt{2}\right)}. \tag{3}$$

Normalizing so the smallest edge has unit edge length $s_1 = 1$ gives a deltoidal icositetrahedron with SURFACE AREA and VOLUME

$$S = 6\sqrt{29-2\sqrt{2}}. \tag{4}$$



$$V = \sqrt{122+71\sqrt{2}}. \tag{5}$$

Demiregular Tessellation

TESSELLATION

Demlo Number

The initially PALINDROMIC NUMBERS 1, 121, 12321, 1234321, 123454321, ... (Sloane's A002477). For the first through ninth terms, the sequence is given by the GENERATING FUNCTION

$$-\frac{10x+1}{(x-1)(10x-1)(100x-1)}$$
$$= 1 + 121x + 12321x^2 + 1234321x^3 + \ldots$$

(Plouffe 1992, Sloane and Plouffe 1995). The definition of this sequence is slightly ambiguous from the tenth term on.

Denjoy Integral

A type of INTEGRAL which is an extension of both the RIEMANN INTEGRAL and the LEBESGUE INTEGRAL. The original Denjoy integral is now called a Denjoy integral "in the restricted sense," and a more general type is now called a Denjoy integral "in the wider sense." The independently discovered PERRON INTEGRAL turns out to be equivalent to the Denjoy integral "in the restricted sense."

Denominator

The number q in a FRACTION p/q.

See also FRACTION, NUMERATOR, RATIO, RATIONAL NUMBER

Dense

A set A in a FIRST-COUNTABLE SPACE is dense in B if $B = A \cup L$, where L is the limit of sequences of elements of A. For example, the rational numbers are dense in the reals. In general, a SUBSET A of X is dense if its CLOSURE $\mathrm{cl(A)} = X$.

See also CLOSURE (SET), DENSITY, DERIVED SET, NOWHERE DENSE, PERFECT SET

Density

DENSITY (POLYGON), DENSITY (SEQUENCE), NATURAL DENSITY

Density (Polygon)

The number q in a STAR POLYGON $\{p/q\}$.

See also STAR POLYGON

Density (Sequence)

Let a SEQUENCE $\{a_i\}_{i=1}^{\infty}$ be strictly increasing and composed of NONNEGATIVE INTEGERS. Call $A(x)$ the number of terms not exceeding x. Then the density is given by $\lim_{x\to\infty} A(x)/x$ if the LIMIT exists.

Density Function

PROBABILITY FUNCTION

Denumerable Set

A SET is denumerable IFF it is EQUIPOLLENT to the finite ORDINAL NUMBERS. (Moore 1982, p. 6; Rubin 1967, p. 107; Suppes 1972, pp. 151–52). However, Ciesielski (1997, p. 64) calls this property "countable." The set ALEPH-0 is most commonly called "denumerable" to "COUNTABLY INFINITE".

Denumerably Infinite

COUNTABLY INFINITE

Depth (Graph)

GRAPH THICKNESS

Depth (Size)

The depth of a box is the horizontal DISTANCE from front to back (usually not necessarily defined to be smaller than the WIDTH, the horizontal DISTANCE from side to side).

See also HEIGHT, WIDTH (SIZE)

Depth (Statistics)

The smallest RANK (either up or down) of a set of data.

See also RANK (STATISTICS)

References

Tukey, J. W. *Explanatory Data Analysis.* Reading, MA: Addison-Wesley, p. 30, 1977.

Depth (Tree)

The depth of a RESOLVING TREE is the number of levels of links, not including the top. The depth of the link is the minimal depth for any RESOLVING TREE of that link. The only links of length 0 are the trivial links. A KNOT of length 1 is always a trivial KNOT and links of depth one are always HOPF LINKS, possibly with a few additional trivial components (Bleiler and Scharlemann 1988). The LINKS of depth two have also been classified (Scharlemann and Thompson 1991).

Derangement

A derangement of n ordered objects, denoted $!n$, is a PERMUTATION in which none of the objects appear in their "natural" (i.e., ordered) place. For example, the only derangements of $\{1,2,3\}$ are $\{2,3,1\}$ and $\{3,1,2\}$, so $!3=2$. Similarly, the derangements of $\{1,2,3,4\}$ are $\{2,1,4,3\}$, $\{2,3,4,1\}$, $\{2,4,1,3\}$, $\{3,1,4,2\}$, $\{3,4,1,2\}$, $\{3,4,2,1\}$, $\{4,1,2,3\}$, $\{4,3,1,2\}$, and $\{4,3,2,1\}$. Derangements are permutations without fixed points (i.e., having no cycles of length one). The derangements of a list of n elements can be computed using `Derangments[n]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

The problem was formulated by P. R. de Montmort in 1708, and solved by him in 1713 (de Montmort 1713–714). Nicholas Bernoulli also solved the problem using the INCLUSION-EXCLUSION PRINCIPLE (de Montmort 1713–714, p. 301; Bhatnagar, p. 8).

The function giving the number of distinct derangements on n elements is called the SUBFACTORIAL $!n$ and is equal to

$$!n \equiv n! \sum_{k=0}^{n} \frac{(-1)^k}{k!} \tag{1}$$

(Bhatnagar, pp. 8–) or

$$!n \equiv \left[\frac{n!}{e}\right], \tag{2}$$

where $k!$ is the usual FACTORIAL and $[x]$ is the NEAREST INTEGER FUNCTION. These are also called RENCONTRES NUMBERS (named after rencontres solitaire), or COMPLETE PERMUTATIONS, or derangements. The number of derangements $!n=d(n)$ of length n satisfy the RECURRENCE RELATIONS

$$d(n)=(n-1)[d(n-1)+d(n-2)] \tag{3}$$

and

$$d(n)=nd(n-1)+(-1)^n, \tag{4}$$

with $d(1)=0$ and $d(2)=1$ (Skiena 1990, p. 33). The first few are 0, 1, 2, 9, 44, 265, 1854, ... (Sloane's A000166). This sequence cannot be expressed as a fixed number of hypergeometric terms (Petkovsek *et al.* 1996, pp. 157–60).

Derivation

A derivation is a sequence of steps, logical or computational, from one result to another. The word derivation comes from the word "derive."

"Derivation" can also refer to a particular type of operator used to define a DERIVATION ALGEBRA on a ring or algebra.

See also DERIVATION ALGEBRA

Derivation Algebra

Let A be any algebra over a FIELD F, and define a derivation of A as a linear operator D on A satisfying

$$(xy)D = (xD)y + x(yD)$$

for all $x, y \in A$. Then the set $D(A)$ of all derivations of A in a SUBSPACE of the associative algebra of all linear operators on A is a LIE ALGEBRA, called the derivation algebra.

See also LIE ALGEBRA

References

Schafer, R. D. *An Introduction to Nonassociative Algebras.* New York: Dover, pp. 3–, 1996.

Derivative

The derivative of a FUNCTION represents an infinitesimal change in the function with respect to whatever parameters it may have. The "simple" derivative of a function f with respect to x is denoted either $f'(x)$ or

$$\frac{df}{dx} \tag{1}$$

(and often written in-line as df/dx). When derivatives are taken with respect to time, they are often denoted using Newton's OVERDOT notation for FLUXIONS,

$$\frac{dx}{dt} = \dot{x}. \tag{2}$$

When a derivative is taken n times, the notation $x^{(n)}$ or

$$\frac{d^n f}{dx^n} \tag{3}$$

is used, with

$$\dot{x}, \ddot{x}, \dddot{x}, \text{ etc.} \tag{4}$$

the corresponding FLUXION notation. When a function $f(x, y, \ldots)$ depends on more than one variable, a PARTIAL DERIVATIVE

$$\frac{\partial f}{\partial x}, \frac{\partial^2 f}{\partial x \partial y}, \text{ etc.} \tag{5}$$

can be used to specify the derivative with respect to one or more variables.

The derivative of a function $f(x)$ with respect to the variable x is defined as

$$f'(x) \equiv \lim_{h \to 0} \frac{f(x+h) - f(x)}{h}. \tag{6}$$

Note that in order for the limit to exist, both $\lim_{h \to 0^+}$ and $\lim_{h \to 0^-}$ must exist and be equal, so the FUNCTION must be continuous. However, continuity is a NECESSARY but *not* SUFFICIENT condition for differentiability. Since some DISCONTINUOUS functions can be integrated, in a sense there are "more" functions which can be integrated than differentiated. In a letter to Stieltjes, Hermite wrote, "I recoil with

dismay and horror at this lamentable plague of functions which do not have derivatives."

A 3-D generalization of the derivative to an arbitrary direction is known as the DIRECTIONAL DERIVATIVE. In general, derivatives are mathematical objects which exist between smooth functions on manifolds. In this formalism, derivatives are usually assembled into "TANGENT MAPS."

Simple derivatives of some simple functions follow.

$$\frac{d}{dx}x^n = nx^{n-1} \tag{7}$$

$$\frac{d}{dx}\ln|x| = \frac{1}{x} \tag{8}$$

$$\frac{d}{dx}\sin x = \cos x \tag{9}$$

$$\frac{d}{dx}\cos x = -\sin x \tag{10}$$

$$\frac{d}{dx}\tan x = \frac{d}{dx}\left(\frac{\sin x}{\cos x}\right) = \frac{\cos x\,\cos x - \sin x(-\sin x)}{\cos^2 x}$$
$$= \frac{1}{\cos^2 x} = \sec^2 x \tag{11}$$

$$\frac{d}{dx}\csc x = \frac{d}{dx}(\sin x)^{-1} = -(\sin x)^{-2}\cos x = -\frac{\cos x}{\sin^2 x}$$
$$= -\csc x\cot x \tag{12}$$

$$\frac{d}{dx}\sec x = \frac{d}{dx}(\cos x)^{-1} = -(\cos x)^{-2}(-\sin x) = \frac{\sin x}{\cos^2 x}$$
$$= \sec x\tan x \tag{13}$$

$$\frac{d}{dx}\cot x = \frac{d}{dx}\left(\frac{\cos x}{\sin x}\right) = \frac{\sin x(-\sin x) - \cos x\cos x}{\sin^2 x}$$
$$= -\frac{1}{\sin^2 x} = -\csc^2 x \tag{14}$$

$$\frac{d}{dx}e^x = e^x \tag{15}$$

$$\frac{d}{dx}a^x = \frac{d}{dx}e^{\ln a^x} = \frac{d}{dx}e^{x\ln a} = (\ln a)e^{x\ln a} = (\ln a)a^x \tag{16}$$

$$\frac{d}{dx}\sin^{-1}x = \frac{1}{\sqrt{1-x^2}} \tag{17}$$

$$\frac{d}{dx}\cos^{-1}x = -\frac{1}{\sqrt{1-x^2}} \tag{18}$$

$$\frac{d}{dx}\tan^{-1}x = \frac{1}{1+x^2} \tag{19}$$

$$\frac{d}{dx}\cot^{-1}x = -\frac{1}{1+x^2} \tag{20}$$

$$\frac{d}{dx}\sec^{-1}x = \frac{1}{x\sqrt{x^2-1}} \tag{21}$$

$$\frac{d}{dx}\csc^{-1}x = -\frac{1}{x\sqrt{x^2-1}} \tag{22}$$

$$\frac{d}{dx}\sinh x = \cosh x \tag{23}$$

$$\frac{d}{dx}\cosh x = \sinh x \tag{24}$$

$$\frac{d}{dx}\tanh x = \operatorname{sech}^2 x \tag{25}$$

$$\frac{d}{dx}\coth x = -\operatorname{csch}^2 x \tag{26}$$

$$\frac{d}{dx}\operatorname{sech} x = -\operatorname{sech} x\tanh x \tag{27}$$

$$\frac{d}{dx}\operatorname{csch} x = -\operatorname{csch} x\coth x \tag{28}$$

$$\frac{d}{dx}\operatorname{sn} x = \operatorname{cn} x\operatorname{dn} x \tag{29}$$

$$\frac{d}{dx}\operatorname{cn} x = -\operatorname{sn} x\operatorname{dn} x \tag{30}$$

$$\frac{d}{dx}\operatorname{dn} x = -k^2\operatorname{sn} x\operatorname{cn} x. \tag{31}$$

where $\operatorname{sn}(x) \equiv \operatorname{sn}(x, k)$, $\operatorname{cn}(x) \equiv \operatorname{cn}(x, k)$, etc. are JACOBI ELLIPTIC FUNCTIONS, and the PRODUCT RULE and QUOTIENT RULE have been used extensively to expand the derivatives.

There are a number of important rules for computing derivatives of certain combinations of functions. Derivatives of sums are equal to the sum of derivatives so that

$$[f(x) + \cdots + h(x)]' = f'(x) + \cdots + h'(x). \tag{32}$$

In addition, if c is a constant,

$$\frac{d}{dx}[cf(x)] = cf'(x). \tag{33}$$

The PRODUCT RULE for differentiation states

$$\frac{d}{dx}[f(x)g(x)] = f(x)g'(x) + f'(x)g(x), \tag{34}$$

where f' denotes the DERIVATIVE of f with respect to x. This derivative rule can be applied iteratively to yield derivate rules for products of three or more

functions, for example,

$$[fgh]' = (fg)h' + (fg)'h = fgh' + (fg' + f'g)h$$
$$= f'gh + fg'h + fgh'. \quad (35)$$

The QUOTIENT RULE for derivatives states that

$$\frac{d}{dx}\left[\frac{f(x)}{g(x)}\right] = \frac{g(x)f'(x) - f(x)g'(x)}{[g(x)]^2} \quad (36)$$

while the POWER RULE gives

$$\frac{d}{dx}(x^n) = nx^{n-1} \quad (37)$$

Other very important rule for computing derivatives is the CHAIN RULE, which states that

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}, \quad (38)$$

or more generally,

$$\frac{dz}{dt} = \frac{\partial z}{\partial x}\frac{dx}{dt} + \frac{\partial z}{\partial y}\frac{dy}{dt}, \quad (39)$$

were $\partial z/\partial x$ denotes a PARTIAL DERIVATIVE.

Miscellaneous other derivative identities include

$$\frac{dy}{dx} = \frac{\frac{dy}{dt}}{\frac{dx}{dt}} \quad (40)$$

$$\frac{dy}{dx} = \frac{1}{\frac{dx}{dy}}. \quad (41)$$

If $F(x,y) = C$, where C is a constant, then

$$dF = \frac{\partial F}{\partial y}dy + \frac{\partial F}{\partial x}dx = 0, \quad (42)$$

so

$$\frac{dy}{dx} = -\frac{\frac{\partial F}{\partial x}}{\frac{\partial F}{\partial y}}. \quad (43)$$

A vector derivative of a vector function

$$\mathbf{X}(t) \equiv \begin{bmatrix} x_1(t) \\ x_2(t) \\ \vdots \\ x_k(t) \end{bmatrix} \quad (44)$$

can be defined by

$$\frac{d\mathbf{X}}{dt} = \begin{bmatrix} \frac{dx_1}{dt} \\ \frac{dx_2}{dt} \\ \vdots \\ \frac{dt_k}{dt} \end{bmatrix} \quad (45)$$

The nth derivatives of $x^n f(x)$ for $n = 1, 2, \ldots$ are

$$\frac{d}{dx}[xf(x)] = f(x) + xf'(x) \quad (46)$$

$$\frac{d^2}{dx^2}\left[x^2 f(x)\right] = 2f(x) + 4xf'(x) + x^2 f''(x) \quad (47)$$

$$\frac{d^3}{dx^3}\left[x^3 f(x)\right] = 6f(x) + 18xf'(x) + 9x^2 f''(x) + x^3 f'''(x). \quad (48)$$

Derivative Test

FIRST DERIVATIVE TEST, SECOND DERIVATIVE TEST

Derived Polygon

Given a POLYGON with an EVEN NUMBER of sides, the derived polygon is obtained by joining the points which are a fractional distance r along each side. If $r = 1/2$, then the derived polygons are called MIDPOINT POLYGONS and tend to a shape with opposite sides parallel and equal in length. Furthermore, alternate polygons have approximately the same length, and the original and all derived polygons have the same centroid.

Amazingly, if $r \neq 1$, the derived polygons still approach a shape with opposite sides parallel and equal in length, and all have the same centroid. The above illustrations show 20 derived polygons for ratios $r =$ 0.3, 0.5, 0.7, and 0.9. More amazingly still, if the original polygon is skew, a plane polygonal is approached which has these same properties.

Dervish

A QUINTIC SURFACE having the maximum possible number of ORDINARY DOUBLE POINTS (31), which was constructed by W. Barth in 1994 (Endraß). The implicit equation of the surface is

$$64(x-w)\left[x^4-4x^3w-10x^2y^2-4x^2w^2\right.$$
$$\left.+16xw^3-20xy^2w+5y^4+16w^4-20y^2w^2\right]$$
$$-5\sqrt{5-\sqrt{5}}\left(2z-\sqrt{5-\sqrt{5}}w\right)$$
$$\times\left[4(x^2+y^2+z^2)+(1+3\sqrt{5})w^2\right]^2, \quad (1)$$

where w is a parameter (Endraß). The surface can also be described by the equation

$$aF+q=0, \quad (2)$$

where

$$F=h_1h_2h_3h_4h_5, \quad (3)$$

$$h_1=x-z \quad (4)$$

$$h2=\cos\left(\frac{2\pi}{5}\right)x-\sin\left(\frac{2\pi}{5}\right)y-z \quad (5)$$

$$h_3=\cos\left(\frac{4\pi}{5}\right)x-\sin\left(\frac{4\pi}{5}\right)y-z \quad (6)$$

$$h_4=\cos\left(\frac{6\pi}{5}\right)x-\sin\left(\frac{6\pi}{5}\right)y-z \quad (7)$$

$$h_5=\cos\left(\frac{8\pi}{5}\right)x-\sin\left(\frac{8\pi}{5}\right)y-z \quad (8)$$

$$q=(1-cz)\left(x^2+y^2-1+rz^2\right)^2, \quad (9)$$

and

$$r = \frac{1}{4}\left(1 + \sqrt{5}\right) \quad (10)$$

$$a = -\frac{8}{5}\left(1 + \frac{1}{\sqrt{5}}\right)\sqrt{5 - \sqrt{5}} \quad (11)$$

$$c = \frac{1}{2}\sqrt{5 - \sqrt{5}} \quad (12)$$

(Nordstrand).

The dervish is invariant under the GROUP D_5 and contains exactly 15 lines. Five of these are the intersection of the surface with a D_5-invariant cone containing 16 nodes, five are the intersection of the surface with a D_5-invariant plane containing 10 nodes, and the last five are the intersection of the surface with a second D_5-invariant plane containing no nodes (Endraß).

Desargues' Configuration

The 10_3 CONFIGURATION of ten lines intersecting three at a time in 10 points which arises in DESARGUES' THEOREM.

See also CONFIGURATION, DESARGUES' THEOREM

Desargues' Theorem

If the three straight LINES joining the corresponding VERTICES of two TRIANGLES ABC and $A'B'C''$ all meet in a point (the PERSPECTIVE CENTER), then the three intersections of pairs of corresponding sides lie on a straight LINE (the PERSPECTIVE AXIS). Equivalently, if two TRIANGLES are PERSPECTIVE from a POINT, they are PERSPECTIVE from a LINE.

The 10 lines and 10 3-line intersections form a 10_3 CONFIGURATION sometimes called DESARGUES' CONFIGURATION.

Desargues' theorem is SELF-DUAL upon application of the DUALITY PRINCIPLE of PROJECTIVE GEOMETRY.

Descartes Circle Theorem

A special case of APOLLONIUS' PROBLEM requiring the determination of a CIRCLE touching three mutually TANGENT CIRCLES (also called the KISSING CIRCLES PROBLEM). There are two solutions: a small circle surrounded by the three original CIRCLES, and a large circle surrounding the original three. Frederick

Soddy gave the FORMULA for finding the RADIUS of the so-called inner and outer SODDY CIRCLES given the RADII of the other three. The relationship is

$$2\left(\kappa_1^2+\kappa_2^2+\kappa_3^2+\kappa_4^2\right)=\left(\kappa_1+\kappa_2+\kappa_3+\kappa_4\right)^2,$$

where κ_i are the CURVATURES of the CIRCLES. Here, the NEGATIVE solution corresponds to the outer SODDY CIRCLE and the POSITIVE solution to the inner SODDY CIRCLE.

This formula was known to Descartes and Viète (Boyer and Merzbach 1991, p. 159), but Soddy extended it to SPHERES. In n-D space, $n+2$ mutually touching n-SPHERES can always be found, and the relationship of their CURVATURES is

$$n\left(\sum_{i=1}^{n+2}\kappa_i^2\right)=\left(\sum_{i=1}^{n+2}\kappa_i\right)^2.$$

Descartes Folium

FOLIUM OF DESCARTES

Descartes Ovals

CARTESIAN OVALS

Descartes Total Angular Defect

The total angular defect is the sum of the ANGULAR DEFECTS over all VERTICES of a POLYHEDRON, where the ANGULAR DEFECT δ at a given VERTEX is the difference between the sum of face angles and 2π. For any convex POLYHEDRON, the Descartes total angular defect is

$$\Delta=\sum_i \delta i=4\pi. \tag{1}$$

This is equivalent to the POLYHEDRAL FORMULA for a closed rectilinear surface, which satisfies

$$\Delta=2\pi(V-E+F). \tag{2}$$

A POLYHEDRON with N_0 equivalent VERTICES is called a PLATONIC SOLID and can be assigned a SCHLÄFLI SYMBOL $\{p,q\}$. It then satisfies

$$N_0=\frac{4\pi}{\delta} \tag{3}$$

and

$$\delta=2\pi-q\left(1-\frac{2}{p}\right)\pi, \tag{4}$$

so

$$N_0=\frac{4p}{2p+2q-pq}. \tag{5}$$

See also ANGULAR DEFECT, PLATONIC SOLID, POLYHEDRAL FORMULA, POLYHEDRON

Descartes' Formula

DESCARTES TOTAL ANGULAR DEFECT

Descartes' Sign Rule

A method of determining the maximum number of POSITIVE and NEGATIVE REAL ROOTS of a POLYNOMIAL.

For POSITIVE ROOTS, start with the SIGN of the COEFFICIENT of the lowest (or highest) POWER. Count the number of SIGN changes n as you proceed from the lowest to the highest POWER (ignoring POWERS which do not appear). Then n is the *maximum* number of POSITIVE ROOTS. Furthermore, the number of allowable ROOTS is n, $n-2$, $n-4$, ... For example, consider the POLYNOMIAL

$$f(x)=x^7+x^6-x^4-x^3-x^2+x-1. \tag{1}$$

Since there are three SIGN changes, there are a maximum of three possible POSITIVE ROOTS.

For NEGATIVE ROOTS, starting with a POLYNOMIAL $f(x)$, write a new POLYNOMIAL $f(-x)$ with the SIGNS of all ODD POWERS reversed, while leaving the SIGNS of the EVEN POWERS unchanged. Then proceed as before to count the number of SIGN changes n. Then n is the *maximum* number of NEGATIVE ROOTS. For example, consider the POLYNOMIAL

$$f(x)=x^7+x^6-x^4-x^3-x^2+x-1, \tag{2}$$

and compute the new POLYNOMIAL

$$f(-x)=-x^7+x^6-x^4+x^3-x^2-x-1. \tag{3}$$

In this example, there are four SIGN changes, so there are a maximum of four NEGATIVE ROOTS.

Descartes-Euler Polyhedral Formula

POLYHEDRAL FORMULA

Descending Plane Partition

$$\begin{array}{cccccc} 7 & 7 & 6 & 6 & 3 & 1 \\ & 6 & 5 & 4 & 2 & \\ & & 3 & 3 & & \\ & & & 2 & & \end{array}$$

A descending plane partition of order n is a 2-D array (possibly empty) of positive integers less than or equal to n such that the left-hand edges are successively indented, rows are nonincreasing across, columns are decreasing downwards, and the number of entries in each row is strictly less than the largest entry in that row. Implicit in this definition are the requirements that no "holes" are allowed in the array, all rows are flush against the top, and the diagonal element *must* be filled if *any* element of its row is filled. The above example shows a decreasing plane partition of order seven.

$$\begin{array}{cc} 3 & 3 \\ & 2 \end{array} \quad 3 \quad 3 \quad 3 \quad 2 \quad 3 \quad 1 \quad 3 \quad 2 \quad \phi$$

The sole descending plane partition of order one is the empty one $\varnothing$, the two of order two are "2" and ϕ, and the seven of order three are illustrated above. In general, the number of descending plane partitions of order n is equal to the number of $+1$-bordered ALTERNATING SIGN MATRICES: 1, 2, 7, 42, 429, ... (Sloane's A005130).

Desmic Surface

Let Δ_1, Δ_2, and Δ_3 be tetrahedra in projective 3-space $\mathbb{P}^3$. Then the tetrahedra are said to be desmically related if there exist constants α, β, and γ such that

$$\alpha\Delta_1 + \beta\Delta_2 + \gamma\Delta_3 = 0.$$

A desmic surface is then defined as a QUARTIC SURFACE which can be written as

$$a\Delta_1 + b\Delta_2 + c\Delta_3 = 0$$

for desmically related tetrahedra Δ_1, Δ_2, and Δ_3. Desmic surfaces have 12 ORDINARY DOUBLE POINTS, which are the vertices of three tetrahedra in 3-space (Hunt).

Destructive Dilemma

A formal argument in LOGIC in which it is stated that

1. $P \Rightarrow Q$ and $R \Rightarrow S$ (where $\Rightarrow$ means "IMPLIES"), and
2. Either not-Q or not-S is true, from which two statements it follows that either not-P or not-R is true.

See also CONSTRUCTIVE DILEMMA, DILEMMA

Determinant

Determinants are mathematical objects which are very useful in the analysis and solution of SYSTEMS OF LINEAR EQUATIONS. As shown by CRAMER'S RULE, a nonhomogeneous system of linear equations has a nontrivial solution IFF the determinant of the system's MATRIX is NONZERO (i.e., the MATRIX is nonsingular). For example, eliminating x, y, and z from the equations

$$a_1x + a_2y + a_3z = 0 \quad (1)$$

$$b_1x + b_2y + b_3z = 0 \quad (2)$$

$$c_1x + c_2y + c_3z = 0 \quad (3)$$

gives the expression

$$a_1b_2c_3 - a_1b_3c_2 + a_2b_3c_1 - a_2b_1c_3 + a_3b_1c_2 - a_3b_2c_1 = 0, \quad (4)$$

which is called the determinant for this system of equation. Determinants are defined only for SQUARE MATRICES. If the determinant of a MATRIX is 0, the MATRIX is said to be a SINGULAR MATRIX.

The determinant of a MATRIX A,

$$\begin{vmatrix} a_1 & a_2 & \cdots & a_n \\ b_1 & b_2 & \cdots & b_n \\ \vdots & \vdots & \ddots & \vdots \\ z_1 & z_2 & \cdots & z_n \end{vmatrix} \quad (5)$$

is commonly denoted $\det \mathsf{A}$, $|\mathsf{A}|$, or in component notation as $\Sigma(\pm a_1b_2c_3\cdots)$, $D(a_1b_2c_3\cdots)$, or $|a_1b_2c_3\cdots|$ (Muir 1960, p. 17).

A 2×2 determinant is defined to be

$$\det\begin{bmatrix} a & b \\ c & d \end{bmatrix} \equiv \begin{vmatrix} a & b \\ c & d \end{vmatrix} \equiv ad - bc. \quad (6)$$

A $k \times k$ determinant can be expanded "by MINORS" to obtain

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1k} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2k} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & a_{k3} & \cdots & a_{kk} \end{vmatrix} = a_{11}\begin{vmatrix} a_{22} & a_{23} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k2} & a_{k3} & \cdots & a_{kk} \end{vmatrix} - a_{12}\begin{vmatrix} a_{21} & a_{23} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k3} & \cdots & a_{kk} \end{vmatrix} + \cdots \pm a_{1k}\begin{vmatrix} a_{21} & a_{22} & \cdots & a_{2(k-1)} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{k(k-1)} \end{vmatrix}. \quad (7)$$

A general determinant for a MATRIX A has a value

$$|\mathsf{A}| = \sum_i a_{ij}a^{ij}, \quad (8)$$

with no implied summation over j and where a^{ij} is the COFACTOR of a_{ij} defined by

$$a^{ij} \equiv (-1)^{i+j}C_{ij}. \quad (9)$$

Here, C is the $(n-1)\times(n-1)$ MATRIX formed by eliminating row i and column j from A. This process is called DETERMINANT EXPANSION BY MINORS (or "Laplacian expansion by minors," sometimes further shortened to simply "Laplacian expansion").

A determinant can also be computed by writing down all PERMUTATIONS of $\{1, \ldots, n\}$, taking each permutation as the subscripts of the letters a, b, ..., and summing with signs determined by $\epsilon_p = (-1)^{i(p)}$, where $i(p)$ is the number of PERMUTATION INVERSIONS in permutation p (Muir 1960, p. 16), and $\epsilon_{n_1n_2}\ldots$ is the PERMUTATION SYMBOL. For example, with $n = 3$, the permutations and the number of inversions they contain are 123 (0), 132 (1), 213 (1), 231 (2), 312 (2), and 321 (3), so the determinant is given by

$$\begin{vmatrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{vmatrix} = a_1b_2c_3 - a_1b_3c_2 - a_2b_1c_3 + a_2b_3c_1 + a_3b_1c_2 - a_3b_2c_1. \quad (10)$$

If c is a constant and A an $n \times n$ SQUARE MATRIX, then

$$|a\mathsf{A}| = a^n|\mathsf{A}|. \quad (11)$$

Given an $n \times n$ determinant, the additive inverse is

$$|-\mathsf{A}| = (-1)^n|\mathsf{A}|. \quad (12)$$

Determinants are also DISTRIBUTIVE, so

$$|\mathsf{AB}| = |\mathsf{A}||\mathsf{B}|. \quad (13)$$

This means that the determinant of a MATRIX INVERSE can be found as follows:

$$|\mathsf{I}| = |\mathsf{AA}^{-1}| = |\mathsf{A}||\mathsf{A}^{-1}| = 1, \quad (14)$$

where I is the IDENTITY MATRIX, so

$$|A| = \frac{1}{|A^{-1}|}. \tag{15}$$

Determinants are MULTILINEAR in rows and columns, since

$$\begin{vmatrix} a_1 & a_2 & a_3 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} = \begin{vmatrix} a_1 & 0 & 0 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} + \begin{vmatrix} 0 & a_2 & 0 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} + \begin{vmatrix} 0 & 0 & a_3 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} \tag{16}$$

and

$$\begin{vmatrix} a_1 & a_2 & a_3 \\ a_4 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix} = \begin{vmatrix} a_1 & a_2 & a_3 \\ 0 & a_5 & a_6 \\ 0 & a_8 & a_9 \end{vmatrix} + \begin{vmatrix} 0 & a_2 & a_3 \\ a_4 & a_5 & a_6 \\ 0 & a_8 & a_9 \end{vmatrix} + \begin{vmatrix} 0 & a_2 & a_3 \\ 0 & a_5 & a_6 \\ a_7 & a_8 & a_9 \end{vmatrix}. \tag{17}$$

The determinant of the SIMILARITY TRANSFORMATION of a matrix is equal to the determinant of the original MATRIX

$$|BAB^{-1}| = |B||A||B^{-1}| = |B||A|\frac{1}{|B|} = |A|. \tag{18}$$

The determinant of a similarity transformation minus a multiple of the unit MATRIX is given by

$$|B^{-1}AB - \lambda I| = |B^{-1}AB - B^{-1}\lambda IB| = |B^{-1}(A - \lambda I)B|$$

$$= |B^{-1}||A - \lambda I||B| = |A - \lambda I|. \tag{19}$$

The determinant of a MATRIX TRANSPOSE equals the determinant of the original MATRIX,

$$|A| = |A^T|, \tag{20}$$

and the determinant of a COMPLEX CONJUGATE is equal to the COMPLEX CONJUGATE of the determinant

$$|\bar{A}| = \overline{|A|}. \tag{21}$$

Let ε be a small number. Then

$$|I + \epsilon A| = 1 + \epsilon \mathrm{Tr}(A) + \mathcal{O}(\epsilon^2), \tag{22}$$

where Tr(A) is the TRACE of A. The determinant takes on a particularly simple form for a TRIANGULAR MATRIX

$$\begin{vmatrix} a_{11} & a_{21} & \cdots & a_{k1} \\ 0 & a_{22} & \cdots & a_{k2} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \vdots & a_{kk} \end{vmatrix} = \prod_{n=1}^{k} a_{nn}. \tag{23}$$

Important properties of the determinant include the following, which include invariance under ELEMENTARY ROW AND COLUMN OPERATIONS.

1. Switching two rows or columns changes the sign.
2. Scalars can be factored out from rows and columns.
3. Multiples of rows and columns can be added together without changing the determinant's value.
4. Scalar multiplication of a row by a constant c multiplies the determinant by c.
5. A determinant with a row or column of zeros has value 0.
6. Any determinant with two rows or columns equal has value 0.

Property 1 can be established by induction. For a 2×2 MATRIX, the determinant is

$$\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = a_1 b_2 - b_1 a_2 = -(b_1 a_2 - a_1 b_2)$$

$$= -\begin{vmatrix} b_1 & a_1 \\ b_2 & a_2 \end{vmatrix} \tag{24}$$

For a 3×3 MATRIX, the determinant is

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = a_1 \begin{vmatrix} b_2 & c_2 \\ b_3 & c_3 \end{vmatrix} - b_1 \begin{vmatrix} a_2 & c_2 \\ a_3 & c_3 \end{vmatrix} + c_1 \begin{vmatrix} a_2 & b_2 \\ a_3 & b_3 \end{vmatrix}$$

$$= -\left(a_1 \begin{vmatrix} c_2 & b_2 \\ c_3 & b_3 \end{vmatrix} + b_1 \begin{vmatrix} c_2 & a_2 \\ c_3 & a_3 \end{vmatrix} - c_1 \begin{vmatrix} a_2 & b_2 \\ a_3 & b_3 \end{vmatrix} \right)$$

$$= -\begin{vmatrix} a_1 & c_1 & b_1 \\ a_2 & c_2 & b_2 \\ a_3 & c_3 & b_3 \end{vmatrix}$$

$$= -\left(-a_1 \begin{vmatrix} b_2 & c_2 \\ b_3 & c_3 \end{vmatrix} + b_1 \begin{vmatrix} a_2 & c_2 \\ a_3 & c_3 \end{vmatrix} + c_1 \begin{vmatrix} b_2 & a_2 \\ b_3 & a_3 \end{vmatrix} \right)$$

$$= -\begin{vmatrix} b_1 & a_1 & c_1 \\ b_2 & a_2 & c_2 \\ b_3 & a_3 & c_3 \end{vmatrix}$$

$$= -\left(-a_1 \begin{vmatrix} c_2 & b_2 \\ c_3 & b_3 \end{vmatrix} - b_1 \begin{vmatrix} a_2 & c_2 \\ a_3 & c_3 \end{vmatrix} + c_1 \begin{vmatrix} b_2 & a_2 \\ b_3 & a_3 \end{vmatrix} \right)$$

$$= -\begin{vmatrix} c_1 & b_1 & a_1 \\ c_2 & b_2 & a_2 \\ c_3 & b_3 & a_3 \end{vmatrix}. \tag{25}$$

Property 2 follows likewise. For 2×2 and 3×3 matrices,

$$\begin{vmatrix} ka_1 & b_1 \\ ka_2 & b_2 \end{vmatrix} = k(a_1 b_2) - k(b_1 a_2) = k \begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} \tag{26}$$

and

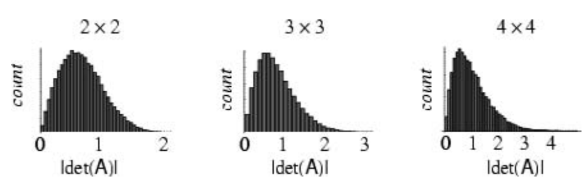
$$\begin{vmatrix} ka_1 & b_1 & c_1 \\ ka_2 & b_2 & c_2 \\ ka_3 & b_3 & c_3 \end{vmatrix} = ka_1 \begin{vmatrix} b_2 & c_2 \\ b_3 & c_3 \end{vmatrix} - b_1 \begin{vmatrix} ka_2 & c_2 \\ ka_3 & c_3 \end{vmatrix}$$

$$+c_1\begin{vmatrix} ka_2 & b_2 \\ ka_3 & b_3 \end{vmatrix} = k\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix}. \qquad (27)$$

Property 3 follows from the identity

$$\begin{vmatrix} a_1+kb_1 & b_1 & c_1 \\ a_2+kb_2 & b_2 & c_2 \\ a_3+kb_3 & b_3 & c_3 \end{vmatrix}$$

$$=(a_1+kb_1)$$



$$\times\begin{vmatrix} b_2 & c_2 \\ b_3 & c_3 \end{vmatrix} - b_1\begin{vmatrix} a+kb_2 & c_2 \\ a_3+kb_3 & c_3 \end{vmatrix} + c_1\begin{vmatrix} a_2+kb_2 & b_2 \\ a_3+kb_3 & b_3 \end{vmatrix}. \qquad (28)$$

If a_{ij} is an $n \times n$ MATRIX with a_{ij} REAL NUMBERS, then $\det[a_{ij}]$ has the interpretation as the oriented n-dimensional CONTENT of the PARALLELEPIPED spanned by the column vectors $[a_{i,1}]$, ..., $[a_{i,n}]$ in $\mathbb{R}^n$.. Here, "oriented" means that, up to a change of + or − SIGN, the number is the n-dimensional CONTENT, but the SIGN depends on the "orientation" of the column vectors involved. If they agree with the standard orientation, there is a + SIGN; if not, there is a − SIGN. The PARALLELEPIPED spanned by the n-D vectors $\mathbf{v}_1$ through $\mathbf{v}_i$ is the collection of points

$$t_1\mathbf{v}_1 + \ldots + t_i\mathbf{v}_i, \qquad (29)$$

where t_j is a REAL NUMBER in the CLOSED INTERVAL $[0, 1]$..

Several accounts state that Lewis Carroll (Charles Dodgson) sent Queen Victoria a copy of one of his mathematical works, in one account, *An Elementary Treatise on Determinants*. Heath (1974) states, "A well-known story tells how Queen Victoria, charmed by *Alice in Wonderland*, expressed a desire to receive the author's next work, and was presented, in due course, with a loyally inscribed copy of *An Elementary Treatise on Determinants*," while Gattegno (1974) asserts "Queen Victoria, having enjoyed *Alice* so much, made known her wish to receive the author's other books, and was sent one of Dodgson's mathematical works." However, in *Symbolic Logic* (1896), Carroll stated, "I take this opportunity of giving what publicity I can to my contradiction of a silly story, which has been going the round of the papers, about my having presented certain books to Her Majesty the Queen. It is so constantly repeated, and is such absolute fiction, that I think it worth while to state, once for all, that it is utterly false in every particular: nothing even resembling it has occurred" (Mikkelson and Mikkelson).

Hadamard (1893) showed that the absolute value of the determinant of a COMPLEX $n \times n$ matrix with entries in the UNIT DISK satisfies

$$|\det \mathsf{A}| \le n^{n/2} \qquad (30)$$

(Brenner 1972). The plots above show the distribution of determinants for random $n \times n$ complex matrices with entries satisfying $|a_{ij}| < 1$ for $n = 2$, 3, and 4.

There are an infinite number of 3×3 determinants with no 0 or $\pm$ 1 entries having unity determinant. One parametric family is

$$\begin{vmatrix} -8n^2-8n & 2n+1 & 4n \\ -4n^2-4n & n+1 & 2n+1 \\ -4n^2-4n-1 & n & 2n-1 \end{vmatrix}. \qquad (31)$$

Specific examples having small entries include

$$\begin{vmatrix} 2 & 3 & 2 \\ 4 & 2 & 3 \\ 9 & 6 & 7 \end{vmatrix}, \begin{vmatrix} 2 & 3 & 5 \\ 3 & 2 & 3 \\ 9 & 5 & 7 \end{vmatrix}, \begin{vmatrix} 2 & 3 & 6 \\ 3 & 2 & 3 \\ 17 & 11 & 16 \end{vmatrix}, \ldots \qquad (32)$$

(Guy 1989, 1994).

Determinant (Binary Quadratic Form)

The determinant of a BINARY QUADRATIC FORM

$$Au^2+2Buv+Cv^2$$

is

$$D\equiv B^2-AC.$$

It is equal to 1/4 of the corresponding DISCRIMINANT.

Determinant (Knot)

KNOT DETERMINANT

Determinant Expansion by Minors

Also known as "Laplacian" determinant expansion by minors, expansion by minors is a technique for computing the DETERMINANT of a given SQUARE MATRIX M. Although efficient for small matrices, techniques such as GAUSSIAN ELIMINATION are much more efficient when the matrix size becomes large.

Let $|\mathsf{M}|$ denote the DETERMINANT of a MATRIX M, then

$$|\mathsf{M}|=\sum_{i=1}^{k}(-1)^{i+j}a_{ij}M_{ij}, \tag{1}$$

where M_{ij} is a so-called MINOR of M, obtained by taking the determinant of M with row i and column j "crossed out." For example, for a 3×3 matrix, the above formula gives

$$\begin{vmatrix}a_{11} & a_{12} & a_{13}\\ a_{21} & a_{22} & a_{23}\\ a_{31} & a_{32} & a_{33}\end{vmatrix} = a_{11}\begin{vmatrix}a_{22} & a_{23}\\ a_{32} & a_{33}\end{vmatrix} - a_{12}\begin{vmatrix}a_{21} & a_{23}\\ a_{31} & a_{33}\end{vmatrix} + a_{13}\begin{vmatrix}a_{21} & a_{22}\\ a_{31} & a_{32}\end{vmatrix}. \tag{2}$$

The procedure can then be iteratively applied to calculate the minors in terms of subminors, etc. The factor $(-1)^{i+j}$ is sometimes absorbed into the minor as

$$|\mathsf{M}|=\sum_{i=1}^{k}a_{ij}C_{ij}, \tag{3}$$

in which case C_{ij} is called a COFACTOR.

The equation for the determinant can also be formally written as

$$|\mathsf{A}|=\sum_{\pi}(-1)^{I(\pi)}\prod_{i=1}^{n}a_{i,\pi(i)}, \tag{4}$$

where π ranges over all permutations of $\{1,2,\ldots,n\}$ and $I(\pi)$ is the INVERSION NUMBER of π (Bressoud and Propp 1999).

Determinant Identities

Interesting DETERMINANT identities include

$$\begin{vmatrix}1 & a & b+c\\ 1 & b & c+a\\ 1 & c & a+b\end{vmatrix}=0 \tag{1}$$

(Muir 1960, p. 39),

$$\begin{vmatrix}a+b+c+d & b & c & d\\ b+c+d+a & c & d & a\\ c+d+a+b & d & a & c\\ d+a+b+c & a & b & c\end{vmatrix}=\begin{vmatrix}1 & b & c & d\\ 1 & c & d & a\\ 1 & d & a & b\\ 1 & a & b & c\end{vmatrix}\times(a+b+c+d) \tag{2}$$

(Muir 1960, p. 41),

$$\begin{vmatrix}1 & a & a^2 & a^3\\ 1 & b & b^2 & b^3\\ 1 & c & c^2 & c^3\\ 1 & d & d^2 & d^3\end{vmatrix}=(b-a)(c-a)(c-b)(d-a)(d-b)\times(d-c) \tag{3}$$

(Muir 1960, p. 42),

$$\begin{vmatrix}bcd & a & a^2 & a^3\\ cda & b & b^2 & b^3\\ dab & c & c^2 & c^3\\ abc & d & d^2 & d^3\end{vmatrix}=\begin{vmatrix}1 & a^2 & a^3 & a^4\\ 1 & b^2 & b^3 & b^4\\ 1 & c^2 & c^3 & c^4\\ 1 & d^2 & d^3 & d^4\end{vmatrix} \tag{4}$$

(Muir 1960, p. 47),

$$\begin{vmatrix}0 & a^2 & b^2 & c^2\\ a^2 & 0 & \gamma^2 & \beta^2\\ b^2 & \gamma^2 & 0 & \alpha^2\\ c^2 & \beta^2 & \alpha^2 & 0\end{vmatrix}=\begin{vmatrix}0 & a\alpha & b\beta & c\gamma\\ a\alpha & 0 & c\gamma & a\alpha\\ b\beta & c\gamma & 0 & a\alpha\\ c\gamma & b\beta & a\alpha & 0\end{vmatrix} \tag{5}$$

(Muir 1960, p. 42),

$$\begin{vmatrix}1 & 1 & 1 & 1\\ 1 & 1+x & 1 & 1\\ 1 & 1 & 1+y & 1\\ 1 & 1 & 1 & 1+z\end{vmatrix}=xyz \tag{6}$$

(Muir 1960, p. 44), and the CAYLEY-MENGER DETERMINANT

$$\begin{vmatrix} 0 & a & b & c \\ a & 0 & c & b \\ b & c & 0 & a \\ c & b & a & 0 \end{vmatrix} = \begin{vmatrix} 0 & 1 & 1 & 1 \\ 1 & 0 & c^2 & b^2 \\ 1 & c^2 & 0 & a^2 \\ 1 & b^2 & a^2 & 0 \end{vmatrix} \tag{7}$$

(Muir 1960, p. 46), which is closely related to HERON'S FORMULA.

Determinant Theorem

Given a MATRIX M, the following are equivalent:

1. $|\mathsf{M}| \neq 0$.
2. The columns of M are linearly independent.
3. The rows of M are linearly independent.
4. Range(M) $= \mathbb{R}^n$..
5. Null(M) $= \{0\}$.
6. M has a MATRIX INVERSE.

Deterministic

A TURING MACHINE is called deterministic if there is always at most one instruction associated with a given present internal state/tape state pair (q, s). Otherwise, it is called nondeterministic (Itô 1987, p. 137).

In prediction theory, let $\{X_t\}$ be a weakly stationary process, and let $M_t(X)$ be a subspace spanned by the X_s (with $s \leq t$). If $M_t(X)$ is independent of t so that $M_t(X) = M(X)$ for every t, then $\{X_t\}$ is said to be deterministic (Itô 1987, p. 1463).

Devil on Two Sticks

DEVIL'S CURVE

Devil's Curve

The devil's curve was studied by G. Cramer in 1750 and Lacroix in 1810 (MacTutor Archive). It appeared in *Nouvelles Annales* in 1858. The Cartesian equation is

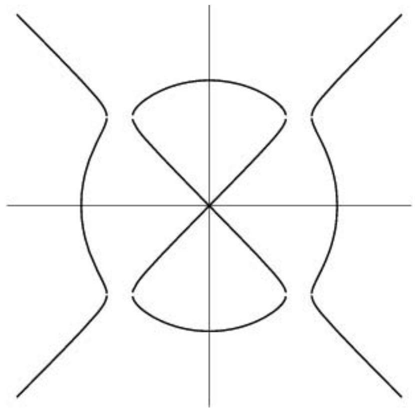
$$y^4 - a^2y^2 = x^4 - b^2x^2, \tag{1}$$

equivalent to

$$y^2(y^2 - a^2) = x^2(x^2 - b^2), \tag{2}$$

the polar equation is

$$r^2(\sin^2\theta - \cos^2\theta) = a^2\sin^2\theta - b^2\cos^2\theta, \tag{3}$$



and the PARAMETRIC EQUATIONS are

$$x = \cos t\sqrt{\frac{a^2\sin^2 t - b^2\cos^2 t}{\sin^2 t - \cos^2 t}} \tag{4}$$

$$y = \sin t\sqrt{\frac{a^2\sin^2 t - b^2\cos^2 t}{\sin^2 t - \cos^2 t}}. \tag{5}$$

The curve illustrated above corresponds to para-

meters $a^2 = 1$ and $b^2 = 2$.

A special case of the Devil's curve is the so-called "electric motor curve":

$$y^2(y^2 - 96) = x^2(x^2 - 100) \quad (6)$$

(Cundy and Rollett 1989).

Devil's Needle Puzzle

BAGUENAUDIER

Devil's Staircase

A plot of the WINDING NUMBER W resulting from MODE LOCKING as a function of Ω for the CIRCLE MAP

$$\theta_{n+1} = \theta_n + \Omega - \frac{K}{2\pi}\sin(2\pi\theta_n)$$

with $K = 1$. (Since the CIRCLE MAP becomes MODE-LOCKED, the WINDING NUMBER is independent of the initial starting argument θ_0.) At each value of Ω, the WINDING NUMBER is some RATIONAL NUMBER. The result is a monotonic increasing "staircase" for which the simplest RATIONAL NUMBERS have the largest steps. The Devil's staircase continuously maps the interval $[0, 1]$ onto $[0, 1]$, but is constant almost everywhere (i.e., except on a CANTOR SET).

For $K = 1$, the MEASURE of quasiperiodic states (Ω IRRATIONAL) on the Ω-axis has become zero, and the measure of MODE-LOCKED state has become 1. The DIMENSION of the Devil's staircase $\approx 0.8700 \pm 3.7 \times 10^{-4}$.

Diagonal

A diagonal of a SQUARE MATRIX which is traversed in the "southeast" direction. "The" diagonal (or "main diagonal" or "principal diagonal"rpar; of an $n \times n$ square matrix is the diagonal from a_{11} to a_{nn}.

See also DIAGONAL MATRIX, DIAGONAL METRIC, DIAGONAL (POLYGON), DIAGONAL (POLYHEDRON), DIAGONAL RAMSEY NUMBER, DIAGONAL SLASH, DIAGONAL TRIANGLE, DIAGONALIZABLE MATRIX, SHALLOW DIAGONAL, SKEW DIAGONAL, SUBDIAGONAL, SUPERDIAGONAL, TRIDIAGONAL MATRIX

Diagonal (Polygon)

A LINE SEGMENT connecting two nonadjacent VERTICES of a POLYGON. The number of ways a fixed convex n-gon can be divided into TRIANGLES by nonintersecting diagonals is C_{n-2} (with C_{n-3} diagonals), where C_n is a CATALAN NUMBER. This is EULER'S POLYGON DIVISION PROBLEM. Counting the number of regions determined by drawing the diagonals of a regular n-gon is a more difficult problem, as is determining the number of n-tuples of CONCURRENT diagonals (Kok 1972).

The number of regions which the diagonals of a CONVEX POLYGON divide its center if no three are concurrent in its interior is

$$N = \binom{n}{4} + \binom{n-1}{4} = \frac{1}{24}(n-1)(n-2)(n^2-3n+12).$$

The first few values are 0, 0, 1, 4, 11, 25, 50, 91, 154, 246, ... (Sloane's A006522).

Diagonal (Polyhedron)

A LINE SEGMENT connecting two nonadjacent sides of a POLYHEDRON. Any polyhedron having no diagonals must have a SKELETON which is a COMPLETE GRAPH (Gardner 1975). The only SIMPLE POLYHEDRON with no diagonals is the TETRAHEDRON. The only known TOROIDAL POLYHEDRON with no diagonals is the CSÁSZÁR POLYHEDRON.

Diagonal (Solidus)

SOLIDUS

Diagonal Block Matrix

BLOCK DIAGONAL MATRIX

Diagonal Matrix

A diagonal matrix is a SQUARE MATRIX A OF THE FORM

$$a_{ij} = c_i \delta_{ij}, \qquad (1)$$

where δ_{ij} is the KRONECKER DELTA, c_i are constants,

and $i, j = 1, 2, ..., n$, with is no implied summation over indices. The general diagonal matrix is therefore OF THE FORM

$$\begin{bmatrix} c_1 & 0 & \cdots & 0 \\ 0 & c_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & c_n \end{bmatrix} \qquad (2)$$

often denoted $\mathrm{diag}(c_1, c_2, \ldots, c_n)$. The diagonal matrix with elements $l = \{c_1, \ldots, c_n\}$ can be computed in *Mathematica* using DiagonalMatrix[l].

Given a MATRIX EQUATION OF THE FORM

$$\begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_n \end{bmatrix} = \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_n \end{bmatrix} \begin{bmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{bmatrix}, \qquad (3)$$

multiply through to obtain

$$\begin{bmatrix} a_{11}\lambda_1 & \cdots & a_{1n}\lambda_n \\ \vdots & \ddots & \vdots \\ a_{n1}\lambda_1 & \cdots & a_{nn}\lambda_n \end{bmatrix} = \begin{bmatrix} a_{11}\lambda_1 & \cdots & a_{1n}\lambda_1 \\ \vdots & \ddots & \vdots \\ a_{n1}\lambda_n & \cdots & a_{nn}\lambda_n \end{bmatrix}. \qquad (4)$$

Since in general, $\lambda_i \neq \lambda_j$ for $i \neq j$, this can be true only if off-diagonal components vanish. Therefore, A must be diagonal.

Given a diagonal matrix T, the MATRIX POWER can be computed simply by taking each element to the power in question,

$$\mathsf{T}^n = \begin{bmatrix} t_1 & 0 & \cdots & 0 \\ 0 & t_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & t_k \end{bmatrix}^n = \begin{bmatrix} t_1^n & 0 & \cdots & 0 \\ 0 & t_2^n & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & t_k^n \end{bmatrix}. \qquad (5)$$

Similarly, a MATRIX EXPONENTIAL can be performed simply by exponentiating each of the diagonal elements,

$$\exp(\mathsf{A}) = \begin{bmatrix} e^{t_1} & 0 & \cdots & 0 \\ 0 & e^{t_2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & e^{t_k} \end{bmatrix}. \qquad (6)$$

Diagonal Metric

A METRIC g_{ij} which is zero for $i \neq j$.

See also METRIC

Diagonal Quadratic Form

If $\mathsf{A} = (a_{ij})$ is a DIAGONAL MATRIX, a special case of a SYMMETRIC MATRIX, then

$$Q(v) = v^{\mathrm{T}}\mathsf{A}v = \sum a_{ii}v_i^2$$

is a diagonal quadratic form, and $Q(v, w) = v^{\mathrm{T}}\mathsf{A}w$ is its associated diagonal SYMMETRIC BILINEAR FORM.

For a general SYMMETRIC MATRIX A, a SYMMETRIC BILINEAR FORM Q may be diagonalized by a nondegenerate $n \times n$ matrix C such that $Q(\mathsf{C}v, \mathsf{C}w)$ is a diagonal form. That is, $\mathsf{C}^{\mathrm{T}}\mathsf{AC}$ is a DIAGONAL MATRIX. Note that C may not be an ORTHOGONAL MATRIX.

Here is a *Mathematica* function to find a matrix C which will diagonalize a symmetric bilinear form, given a SYMMETRIC MATRIX.

```
DiagonalizerMatrix[a_List?MatrixQ] := Module[
   {
    q, ctr, t2,
   v1 = Prepend[Table[0, {Length[a] - 1}], 1]
   },
   q[v_] := v.a.v;
      If[(t2 = q[v1]) != 0, v1 /=
Sqrt[Abs[t2]]];
   ctr = {v1};
   Do[
    v1 = NullSpace[ctr.a][[1]];
       If[(t2 = q[v1]) != 0, v1 /=
Sqrt[Abs[t2]]];
    AppendTo[ctr, v1],
    {Length[a] - 1}
   ];
   Transpose[Sort[ctr, q[#1] > q[#2] &]]
  ]
```

For example, consider

$$\mathsf{A} = \begin{bmatrix} 1 & 2 \\ 2 & 3 \end{bmatrix}.$$

Then taking

$$\mathsf{C} = \begin{bmatrix} 1 & -2 \\ 0 & 1 \end{bmatrix}$$

gives

$$\mathsf{C}^{\mathrm{T}}\mathsf{AC} = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix},$$

so A has SIGNATURE $(1, 1)$.

Diagonalizable Matrix

This entry contributed by Viktor Bengtsson

An $n \times n$-matrix A is said to be diagonalizable if it can be written on the form

$$\mathsf{A} = \mathsf{PDP}^{-1},$$

where D is a diagonal $n \times n$ matrix with the eigenvalues of A as its entries and P is an invertible $n \times n$ matrix consisting of the eigenvectors corresponding to the eigenvalues in D.

The diagonalization theorem states that a quadratic matrix A is diagonalizable if and only if A has n linearly independent eigenvectors. Diagonalization (and most other forms of matrix factorisation) are particularly useful when studying linear transformations, discrete dynamical systems, continuous systems, and so on.

Diameter

The diameter of a circle is the distance from a point on the circle to a point π Radians away, and is the maximum distance from one point on a circle to another. The diameter of a sphere is the maximum distance between two antipodal points on the surface of the sphere.

If r is the radius of a circle or sphere, then $d = 2r$. The ratio of the circumference C of a circle or great circle of a sphere to the diameter d is pi,

$$\pi = \frac{C}{d}.$$

Dice

A die (plural "dice") is a SOLID with markings on each of its faces. The faces are usually all the same shape, making PLATONIC SOLIDS and ARCHIMEDEAN SOLID DUALS the obvious choices. The die can be "rolled" by throwing it in the air and allowing it to come to rest on one of its faces. Dice are used in many games of chance as a way of picking RANDOM NUMBERS on which to bet, and are used in board or role-playing games to determine the number of spaces to move, results of a conflict, etc. A COIN can be viewed as a degenerate 2-sided case of a die.

The most common type of die is a six-sided CUBE with the numbers 1– placed on the faces. The value of the roll is indicated by the number of "spots" showing on the top. For the six-sided die, opposite faces are arranged to always sum to seven. This gives two possible MIRROR IMAGE arrangements in which the numbers 1, 2, and 3 may be arranged in a clockwise or counterclockwise order about a corner. Commercial dice may, in fact, have either orientation. The illustrations below show 6-sided dice with counterclockwise and clockwise arrangements, respectively.

The CUBE has the nice property that there is an upward-pointing face opposite the bottom face from which the value of the "roll" can easily be read. This would not be true, for instance, for a TETRAHEDRAL die, which would have to be picked up and turned over to reveal the number underneath (although it could be determined by noting which number 1– was *not* visible on one of the upper three faces). The arrangement of spots  corresponding to a roll of 5 on a six-sided die is called the QUINCUNX. There are also special names for certain rolls of two six-sided dice: two 1s are called SNAKE EYES and two 6s are called BOXCARS.

Shapes of dice other than the usual 6-sided CUBE are commercially available from companies such as Dice & Games, Ltd. ® Diaconis and Keller (1989) show that there exist "fair" dice other than the usual PLATONIC SOLIDS and duals of the ARCHIMEDEAN SOLIDS, where a fair die is one for which its symmetry group acts transitively on its faces (i.e., ISOHEDRA). There are 30 isohedra.

The probability of obtaining p points (a roll of p) on n s-sided dice can be computed as follows. The number of ways in which p can be obtained is the COEFFICIENT of x^p in

$$f(x) = \left(x + x^2 + \ldots + x^s\right)^n \tag{1}$$

since each possible arrangement contributes one term. $f(x)$ can be written as a MULTINOMIAL SERIES

$$f(x) = x^n \left(\sum_{i=0}^{s-1} x^i\right)^n = x^n \left(\frac{1-x^s}{1-x}\right)^n, \tag{2}$$

so the desired number c is the COEFFICIENT of x^p in

$$x^n (1-x^s)^n (1-x)^{-n}. \tag{3}$$

Expanding,

$$x^n \sum_{k=0}^{n} (-1)^k \binom{n}{k} x^{sk} \sum_{l=0}^{\infty} \binom{n+l-1}{l} x^l, \tag{4}$$

so in order to get the COEFFICIENT of x^p, include all terms with

$$p = n + sk + l. \tag{5}$$

c is therefore

$$c = \sum_{k=0}^{n} (-1)^k \binom{n}{k} \binom{p-sk-1}{p-sk-n}. \tag{6}$$

But $p - sk - n > 0$ only when $k < (p-n)/s$, so the other terms do not contribute. Furthermore,

$$\binom{p-sk-1}{p-sk-n} = \binom{p-sk-1}{n-1}, \tag{7}$$

so

$$c = \sum_{k=0}^{\lfloor (p-n)/s \rfloor} (-1)^k \binom{n}{k} \binom{p-sk-1}{n-1}, \tag{8}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, and

$$P(p,n,s) = \frac{1}{s^n} \sum_{k=0}^{\lfloor (p-n)/s \rfloor} (-1)^k \binom{n}{k} \binom{p-sk-1}{n-1} \tag{9}$$

(Uspensky 1937, pp. 23–4).

Consider now $s = 6$. For $n = 2$ six-sided dice,

$$k_{\max} \equiv \left\lfloor \frac{p-2}{6} \right\rfloor = \begin{cases} 0 & \text{for } 2 \leq p \leq 7 \\ 1 & \text{for } 12 \leq p \leq 8, \end{cases} \tag{10}$$

and

$$P(p,2,6) = \frac{1}{6^2} \sum_{k=0}^{k_{\max}} (-1)^k \binom{2}{k} \binom{p-6k-1}{1}$$

$$= \frac{1}{6^2} \sum_{k=0}^{k_{\max}} (-1)^k \frac{2!}{k!(2-k)!} (p-6k-1)$$

$$= \frac{1}{36} \sum_{k=0}^{k_{\max}} (1-2k)(k+1)(p-6k-1)$$

$$\frac{1}{36} \begin{cases} p-1 & \text{for } 2 \le p \le 7 \\ 13-p & \text{for } 8 \le p \le 12 \end{cases}$$

$$= \frac{6-|p-7|}{36} \quad \text{for } 2 \le p \le 12. \qquad (11)$$

The most common roll is therefore seen to be a 7, with probability $6/36 = 1/6$, and the least common rolls are 2 and 12, both with probability 1/36.

For $n = 3$ six-sided dice,

$$k_{\max} = \left\lfloor \frac{vp-3}{6} \right\rfloor = \begin{cases} 0 & \text{for } 3 \le p \le 8 \\ 1 & \text{for} 9 \le p \le 14 \\ 2 & \text{for} 15 \le p \le 18 \end{cases}, \qquad (12)$$

and

$$P(p, 3, 6)$$

$$= \frac{1}{6^3} \sum_{k=0}^{k_{\max}} (-1)^k \binom{3}{k} \binom{p-6k-1}{2}$$

$$= \frac{1}{6^3} \sum_{k=0}^{k_{\max}} (-1)^k \frac{3!}{k!(3-k)!} \frac{(p-6k-1)(p-6k-2)}{2}$$

$$= \frac{1}{216}$$

$$\times \begin{cases} \frac{(p-1)(p-2)}{2} \\ \quad \text{for } 3 \le p \le 8 \\ \frac{(p-1)(p-2)}{2} - 3\frac{(p-7)(p-8)}{2} \\ \quad \text{for } 9 \le p \le 14 \\ \frac{(p-1)(p-2)}{2} - 3\frac{(p-7)(p-8)}{2} + 3\frac{(p-13)(p-14)}{2} \\ \quad \text{for } 15 \le p \le 18 \end{cases}.$$

$$= \frac{1}{216} \begin{cases} \frac{1}{2}(p-1)(p-2) & \text{for } 3 \le p \le 8 \\ -p^2 + 21p - 83 & \text{for } 9 \le p \le 14 \\ \frac{1}{2}(19-p)(20-p) & \text{for } 15 \le p \le 18. \end{cases} \qquad (13)$$

For three six-sided dice, the most common rolls are 10 and 11, both with probability 1/8; and the least common rolls are 3 and 18, both with probability 1/216.

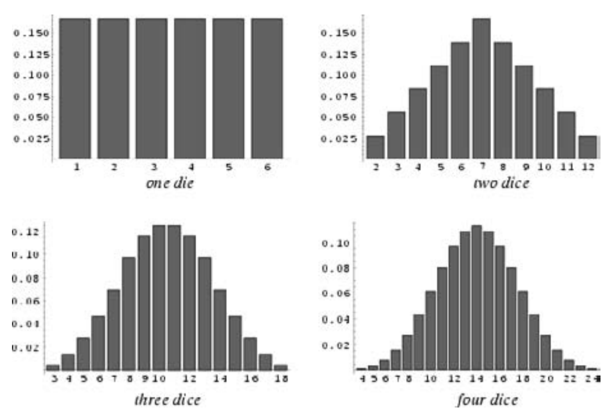
For four six-sided dice, the most common roll is 14, with probability 73/648; and the least common rolls are 4 and 24, both with probability 1/1296.

In general, the likeliest roll p_L for n s-sided dice is given by

$$p_L(n, s) = \left\lfloor \frac{1}{2} n(s+1) \right\rfloor, \qquad (14)$$

which can be written explicitly as

$$p_L(n, s) = \begin{cases} \frac{1}{2} n(s+1) & \text{for } n \text{ even} \\ \frac{1}{2}[n(s+1)-1] & \text{for } n \text{ odd, } s \text{ even} \\ \frac{1}{2} n(s+1) & \text{for } n \text{ odd, } s \text{ odd.} \end{cases} \qquad (15)$$



For 6-sided dice, the likeliest rolls are given by

$$p_L(n, 6) = \left\lfloor \frac{7}{2} n \right\rfloor = \begin{cases} \frac{7}{2} n & \text{for n even} \\ \frac{1}{2}(7n-1) & \text{for n odd,} \end{cases} \qquad (16)$$

or 7, 10, 14, 17, 21, 24, 28, 31, 35, ... for $n = 2, 3, \ldots$ (Sloane's A030123) dice. The probabilities corresponding to the most likely rolls can be computed by plugging $p = p_L$ into the general formula together with

$$k_L(n, s) = \begin{cases} \frac{1}{2} n & \text{for } n \text{ even} \\ \left\lfloor \frac{n(s-1)-1}{2s} \right\rfloor & \text{for } n \text{ odd, } s \text{ even} \\ \left\lfloor \frac{n(s-1)}{2s} \right\rfloor & \text{for } n \text{ odd, } s \text{ odd.} \end{cases} \qquad (17)$$

Unfortunately, $P(p_L, n, s)$ does not have a simple closed-form expression in terms of s and n. However, the probabilities of obtaining the likeliest roll totals can be found explicitly for a particular s. For n 6-sided dice, the probabilities are 1/6, 1/8, 73/648, 65/648, 361/3888, 24017/279936, 7553/93312, ... for $n = 2, 3, \ldots$.

The probabilities for obtaining a given total using n 6-sided dice are shown above for $n = 1, 2, 3$, and 4 dice. They can be seen to approach a GAUSSIAN DISTRIBUTION as the number of dice is increased.

Dichroic Polynomial

A POLYNOMIAL $Z_G(q, v)$ in two variables for abstract GRAPHS. A GRAPH with one VERTEX has $Z = q$. Adding a VERTEX not attached by any EDGES multiplies the Z by q. Picking a particular EDGE of a GRAPH G, the POLYNOMIAL for G is defined by adding the POLYNOMIAL of the GRAPH with that EDGE deleted to v times the POLYNOMIAL of the graph with that EDGE collapsed to a point. Setting $v = -1$ gives the number of distinct VERTEX colorings of the GRAPH. The dichroic POLYNOMIAL of a PLANAR GRAPH can be expressed as the SQUARE BRACKET POLYNOMIAL of the corresponding ALTERNATING LINK by

$$Z_G(q, v) = q^{N/2} B_{L(G)},$$

where N is the number of VERTICES in G. Dichroic POLYNOMIALS for some simple GRAPHS are

$$Z_{K_1} = q$$

$$Z_{K_2} = q^2 + vq$$

$$Z_{K_3} = q^3 + 3vq^2 + 3v^2q + v^3.$$

Dickman Function

The probability that a random integer between 1 and x will have its GREATEST PRIME FACTOR $\leq x^\alpha$ approaches a limiting value $F(\alpha)$ as $x \to \infty$, where $F(\alpha) = 1$ for $\alpha > 1$ and

$$F(\alpha) = \int_0^\alpha F\left(\frac{t}{1-t}\right)\frac{dt}{t}$$

for $0 \leq \alpha \leq 1$ (Dickman 1930, Knuth 1997). Similarly, the second-largest prime factor will be $\leq x^\beta$ with approximate probability $G(\beta)$, where $G(\beta) = 1$ for $\beta \geq 1/2$ and

$$G(\beta) = \int_0^\beta \left[G\left(\frac{t}{1-t}\right) - F\left(\frac{t}{1-t}\right)\right]\frac{dt}{t}$$

for $0 \leq \beta \leq 1/2$..

Dido's Problem

Find the figure bounded by a line which has the maximum AREA for a given PERIMETER. The solution is a SEMICIRCLE. The problem is based on a passage from Virgil's *Aeneid*: "The Kingdom you see is Carthage, the Tyrians, the town of Agenor;

But the country around is Libya, no folk to meet in war.

Dido, who left the city of Tyre to escape her brother,

Rules here–a long a labyrinthine tale of wrong

Is hers, but I will touch on its salient points in order....

Dido, in great disquiet, organised her friends for escape.

They met together, all those who harshly hated the tyrant

Or keenly feared him: they seized some ships which chanced to be ready...

They came to this spot, where to-day you can behold the mighty

Battlements and the rising citadel of New Carthage,

And purchased a site, which was named 'Bull's Hide' after the bargain

By which they should get as much land as they could enclose with a bull's hide."

Bringhurst, R. *The Elements of Typographic Style, 2nd ed.* Point Roberts, WA: Hartley and Marks, 1997.

Diffeomorphic

See also Diffeomorphism

Diffeomorphism

A diffeomorphism is a map between manifolds which is differentiable and has a differentiable inverse.

See also Anosov Diffeomorphism, Axiom A Diffeomorphism, Diffeomorphic, Pesin Theory, Symplectic Diffeomorphism, Tangent Map

Difference

The difference of two numbers n_1 and n_2 is $n_1 - n_2$, where the minus sign denotes subtraction.

See also Backward Difference, Finite Difference, Forward Difference, Minus, Subtraction, Symmetric Difference

Difference Equation

A difference equation is the discrete analog of a differential equation. A difference equation involves a function with integer-valued arguments $f(n)$ in a form like

$$f(n) - f(n-1) = g(n), \qquad (1)$$

where g is some function. The above equation is the discrete analog of the first-order ordinary differential equation

$$f'(x) = g(x) \qquad (2)$$

Examples of difference equations often arise in dynamical systems. Examples include the iteration involved in the Mandelbrot and Julia set definitions,

$$f(n+1) = f(n)^2 + c, \qquad (3)$$

with c a constant, as well as the logistic equation

$$f(n+1) = rf(n)[1 - f(n)], \qquad (4)$$

with r a constant.

Difference of Successes

If x_1/n_1 and x_2/n_2 are the observed proportions from standard normally distributed samples with proportion of success θ, then the probability that

$$w \equiv \frac{x_1}{n_1} - \frac{x_2}{n_2} \qquad (1)$$

will be as great as observed is

$$P_\delta = 1 - 2\int_0^{|\delta|} \phi(t)\,dt \qquad (2)$$

where

$$\delta \equiv \frac{w}{\sigma_w} \qquad (3)$$

$$\sigma_w \equiv \sqrt{\hat{\theta}(1-\hat{\theta})\left(\frac{1}{n_1 +} \frac{1}{n_2}\right)} \qquad (4)$$

$$\hat{\theta} \equiv \frac{x_1 + x_2}{n_1 + n_2}. \quad (5)$$

Here, $\hat{\theta}$ is the UNBIASED ESTIMATOR. The SKEWNESS and KURTOSIS of this distribution are

$$\gamma_1^2 = \frac{(n_1 - n_2)^2}{n_1 n_2 (n_1 + n_2)} \frac{1 - 4\hat{\theta}(1 - \hat{\theta})}{\hat{\theta}(1 - \hat{\theta})} \quad (6)$$

$$\gamma_2 = \frac{n_1^2 - n_1 n_2 + n_2^2}{n_1 n_2 (n_1 + n_2)} \frac{1 - 6\hat{\theta}(1 - \hat{\theta})}{\hat{\theta}(1 - \hat{\theta})}. \quad (7)$$

Difference Operator

BACKWARD DIFFERENCE, FORWARD DIFFERENCE

Difference Quotient

$$\Delta_h f(x) \equiv \frac{f(x+h) - f(x)}{h} = \frac{\Delta f}{h}.$$

It gives the slope of the SECANT LINE passing through $f(x)$ and $f(x+h)$. In the limit $n \to 0$, the difference quotient becomes the PARTIAL DERIVATIVE

$$\lim_{h \to 1} \Delta_{x(h)} f(x, y) = \frac{\partial f}{\partial x}.$$

Difference Set

Let G be a GROUP of ORDER h and D be a set of k elements of G. If the set of differences $d_i - d_j$ contains every NONZERO element of G exactly λ times, then D is a (h, k, λ)-difference set in G of ORDER $n = k - \lambda$. If $\lambda = 1$, the difference set is called planar. The quadratic residues in the FINITE FIELD $GF(11)$ form a difference set. If there is a difference set of size k in a group G, then $2\binom{k}{2}$ must be a multiple of $|G| - 1$, where $\binom{k}{2}$ is a BINOMIAL COEFFICIENT.

Different

Two quantities are said to be different (or "unequal") if they are not EQUAL.

The term "different" also has a technical usage related to MODULES. Let a MODULE M in an INTEGRAL DOMAIN D_1 for $R(\sqrt{D})$ be expressed using a two-element basis as

$$M = [\xi_1, \xi_2],$$

where ξ_1 and ξ_2 are in D_1. Then the different of the MODULE is defined as

$$\Delta = \Delta(M) = \begin{vmatrix} \xi_1 & \xi_2 \\ \xi_1' & \xi_2' \end{vmatrix} = \xi_1 \xi_2' - \xi_1' \xi_2.$$

The different $\Delta \neq 0$ IFF ξ_1 and ξ_2 are linearly independent. The DISCRIMINANT is defined as the square of the different.

See also DISCRIMINANT (MODULE), EQUAL, MODULE

Different Prime Factors

DISTINCT PRIME FACTORS

Differentiable

A REAL FUNCTION is said to be differentiable at a point if its DERIVATIVE exists at that point. The notion of differentiability can also be extended to COMPLEX FUNCTIONS (leading to the CAUCHY-RIEMANN EQUATIONS and the theory of HOLOMORPHIC FUNCTIONS), although a few additional subtleties arise in COMPLEX DIFFERENTIABILITY that are not present in the real case.

Amazingly, there exist CONTINUOUS FUNCTIONS which are nowhere differentiable. Two examples are the BLANCMANGE FUNCTION and WEIERSTRASS FUNCTION.

Differential Equation

An equation which involves the DERIVATIVES of a function as well as the function itself. If PARTIAL DERIVATIVES are involved, the equation is called a PARTIAL DIFFERENTIAL EQUATION; if only ordinary DERIVATIVES are present, the equation is called an ORDINARY DIFFERENTIAL EQUATION. Differential equations play an extremely important and useful role in applied math, engineering, and physics, and much mathematical and numerical machinery has been developed for the solution of differential equations.

Differential Ideal

A differential ideal $\mathfrak{I}$ on a MANIFOLD M is an IDEAL in the EXTERIOR ALGEBRA of DIFFERENTIAL K-FORMS on M which is also CLOSED under the EXTERIOR DERIVATIVE d. That is, for any differential form α and any form $\beta \in \mathfrak{I}$, then

1. $\alpha \wedge \beta \in \mathfrak{I}$, and
2. $d\beta \in \mathfrak{I}$

For example, $\mathfrak{I} = \langle xdy, dx \wedge dy \rangle$ is a differential ideal on $M = \mathbb{R}^2$.

A smooth map $f : X \to M$ is called an integral of $\mathfrak{I}$ if the PULLBACK MAP of all forms in $\mathfrak{I}$ vanish on X, i.e., $f^*(\mathfrak{I}) = 0$.

See also DIFFERENTIAL FORM, ENVELOPE (FORM), INTEGRABLE (DIFFERENTIAL IDEAL), MANIFOLD

Differential k-Form

A differential k-form is a TENSOR of RANK k which is antisymmetric under exchange of any pair of indices. The number of ALGEBRAICALLY INDEPENDENT components in n-D is given by the BINOMIAL COEFFICIENT $\binom{n}{k}$. In particular, a ONE-FORM ω^1 (often simply called a "differential") is a quantity

$$\omega^1 = b_1 dx_1 + b_2 dx_2 + \ldots + b_n dx_n, \tag{1}$$

where $b_1 = b_1(x_1, x_2, \ldots, x_n)$ and $b_2 = b_2(x_1, x_1, \ldots, x_n)$ are the components of a COVARIANT TENSOR. Changing variables from $\mathbf{x}$ to $\mathbf{y}$ gives

$$\omega^1 = \sum_{i=1}^{n} b_i dx_i = \sum_{i=1}^{n} \sum_{j=1}^{n} b_i \frac{\partial x_i}{\partial y_j} dy_j = \sum_{j=1}^{n} \bar{b}_j dy_j, \tag{2}$$

where

$$\bar{b}_j \equiv \sum_{i=1}^{n} b_j \frac{\partial x_i}{\partial y_j}, \tag{3}$$

which is the covariant transformation law.

A p-ALTERNATING MULTILINEAR FORM on a VECTOR SPACE V corresponds to an element of $\wedge^p V^*$, the pth EXTERIOR POWER of the DUAL SPACE to V. A differential p-form on a MANIFOLD is a SECTION of the VECTOR BUNDLE $\wedge^p T^*M$, the pth EXTERIOR POWER of the COTANGENT BUNDLE. Hence, it is possible to write a p-form in coordinates by

$$\sum_{|I|=p} a_I dx_{i_1} \wedge \ldots \wedge dx_{i_p} \tag{4}$$

where I ranges over all increasing subsets of p elements from $\{1, \ldots, n\}$, and the a_I are functions.

An important operation on differential forms, the EXTERIOR DERIVATIVE, is used in the celebrated STOKES' THEOREM. The EXTERIOR DERIVATIVE d of a p form is a $(p+1)$-form. In fact, by definition, if x_i is the coordinate function, thought of as a ZERO-FORM, then $d(x_i) = dx_i$.

Another important operation on forms is the WEDGE PRODUCT, or exterior product. If α is a p-form and β is q-form, then $\alpha \wedge \beta$ is a $p+q$ form. Also, a p-form can be CONTRACTED with an r-vector, i.e., a SECTION of $\wedge^r TM$, to give a $(p-r)$-form, or if $r > p$, an $(r-p)$-vector. If the manifold has a METRIC, then there is an operation dual to the exterior product, called the INTERIOR PRODUCT.

In higher dimensions, there are more kinds of differential forms. For instance, on the TANGENT SPACE to $\mathbb{R}^2$ there is the ZERO-FORM 1, two ONE-FORMS dx and dy, and one TWO-FORM $dx \wedge dy$. A ONE-FORM can be written uniquely as $f dx + g dy$. In four dimensions, $dx_1 \wedge dx_2 + dx_3 \wedge dx_4$ is a TWO-FORM which cannot be written as $a \wedge b$.

The minimum number of terms necessary to write a form is sometimes called the rank of the form, usually in the case of a TWO-FORM. When a form has rank one, it is called DECOMPOSABLE. Another meaning for rank of a form is its rank as a TENSOR, in which case a p-form can be described as an ANTISYMMETRIC TENSOR of rank p, in fact of type $(0, p)$. The rank of a form can also mean the dimension of its ENVELOPE, in which case the rank is an integer-valued function. With the latter definition of rank, a p-form is decomposable IFF it has rank p.

When n is the dimension of a MANIFOLD M, then n is also the dimension of the TANGENT SPACE TM_x. Consequently, an n-form always has rank one, and for $p > n$, a p-form must be zero. Hence, an n-form is called a TOP-DIMENSIONAL FORM. A TOP-DIMENSIONAL FORM can be INTEGRATED without using a METRIC. Consequently, a p-form can be integrated on a p-dimensional SUBMANIFOLD. Differential forms are a VECTOR SPACE (with a C-INFINITY TOPOLOGY) and therefore have a dual space. Submanifolds represent an element of the dual via integration, so it is common to say that they are in the dual space of forms, which is the space of CURRENTS. With a METRIC, the HODGE STAR operator $*$ defines a map from p-forms to $(n-p)$-forms such that $** = (-1)^{p(n-p)}$.

When $f: M \to N$ is a SMOOTH MAP, it pushes forward TANGENT VECTORS from TM to TN according to the JACOBIAN f_*. Hence, a differential form on N pulls back to a differential form on M.

$$f^*\alpha(v_1 \wedge \ldots \wedge v_p) = \alpha(f_* v_1 \wedge \ldots \wedge f_* v_p) \tag{5}$$

The PULLBACK MAP is a linear map which commutes with the EXTERIOR DERIVATIVE,

$$f^*(d\alpha) = df^*(\alpha). \tag{6}$$

Differential Operator

The OPERATOR representing the computation of a DERIVATIVE,

$$\tilde{D} \equiv \frac{d}{dx}. \tag{1}$$

The second derivative is then denoted $\tilde{D}^2$, the third $\tilde{D}^3$, etc. The INTEGRAL is denoted $\tilde{D}^{-1}$.

The differential operator satisfies the identity

$$x - \frac{d}{dx} = -e^{x^2/2} \frac{d}{dx} e^{-x^2/2} \tag{2}$$

(Arfken 1985, p. 720). Furthermore,

$$\left(2x - \frac{d}{dx}\right)^n 1 = H_n(x), \tag{3}$$

where $H_n(x)$ is a HERMITE POLYNOMIAL.

The symbol ϑ can be used to denote the operator

$$\vartheta \equiv z \frac{d}{dz} \tag{4}$$

(Bailey 1935, p. 8).

Digamma Function

A SPECIAL FUNCTION which is given by the LOGARITHMIC DERIVATIVE of the GAMMA FUNCTION (or, depending on the definition, the LOGARITHMIC DERIVATIVE of the FACTORIAL). Because of this ambiguity, two different notations are sometimes (but not always) used, with

$$\Psi(z) \equiv \frac{d}{dz} \ln \Gamma(z) = \frac{\Gamma'(z)}{\Gamma(z)} \tag{1}$$

defined as the LOGARITHMIC DERIVATIVE of the GAMMA FUNCTION $\Gamma(z)$, and

$$F(z) \equiv \frac{d}{dz} \ln z! \tag{2}$$

defined as the LOGARITHMIC DERIVATIVE of the FACTORIAL function. The two are connected by the relationship

$$F(z) = \Psi(z+1). \tag{3}$$

The nth DERIVATIVE of $\Psi(z)$ is called the POLYGAMMA FUNCTION, denoted $\psi_n(z)$. The notation $\psi_0(z) = \Psi(z)$ is therefore frequently used for the digamma function itself, and Erdélyi *et al.* (1981) use the notation $\psi(z)$ for $\Psi(z)$. The function $\Psi(z) = \psi_0(z)$ is returned by the function `PolyGamma[z]` or `PolyGamma[0, z]` in *Mathematica*.

From a series expansion of the FACTORIAL function,

$$\psi_0(z+1) = \frac{d}{dz} \times \lim_{n \to \infty} [\ln n! + z \ln n - \ln(z+1) - \ln(z+2) - \ldots - \ln(z+n)] \tag{4}$$

$$= \lim_{n\to\infty}\left(\ln n - \frac{1}{z+1} - \frac{1}{z+2} - \ldots - \frac{1}{z+n}\right) \quad (5)$$

$$= -\gamma - \sum_{n=1}^{\infty}\left(\frac{1}{z+1} - \frac{1}{n}\right) \quad (6)$$

$$= -\gamma + \sum_{n=1}^{\infty}\frac{z}{n(n+z)} \quad (7)$$

$$= \ln z + \frac{1}{2z} - \sum_{n=1}^{\infty}\frac{B_{2n}}{2nz^{2n}}, \quad (8)$$

where γ is the EULER-MASCHERONI CONSTANT and B_{2n} are BERNOULLI NUMBERS.

The digamma function satisfies

$$\psi_0(z) = \int_0^{\infty}\left(\frac{e^{-t}}{t} - \frac{e^{-zt}}{1-e^{-t}}\right)dt. \quad (9)$$

For integral $z \equiv n$,

$$\psi_0(n) = -\gamma + \sum_{k=1}^{n-1}\frac{1}{k} = -\gamma + H_{n-1}, \quad (10)$$

where γ is the EULER-MASCHERONI CONSTANT and H_n is a HARMONIC NUMBER. Other identities include

$$\frac{d\psi_0}{dz} = \sum_{n=0}^{\infty}\frac{1}{(z+n)^2} \quad (11)$$

$$\psi_0(1-z) - \psi_0(z) = \pi\cot(\pi z) \quad (12)$$

$$\psi_0(z+1) = \psi_0(z) + \frac{1}{z} \quad (13)$$

$$\psi_0(2z) = \frac{1}{2}\psi_0(z) + \frac{1}{2}\psi_0\left(z+\frac{1}{2}\right) + \ln 2. \quad (14)$$

Special values are

$$\psi_0\left(\frac{1}{2}\right) = -\gamma - 2\ln 2 \quad (15)$$

$$\psi_0(1) = -\gamma. \quad (16)$$

At integral values,

$$\psi_0(n+1) = -\gamma + \sum_{k=1}^{n}\frac{1}{k}, \quad (17)$$

and at half-integral values,

$$\psi_0\left(\frac{1}{2}+n\right) = -\gamma - 2\ln 2 + 2\sum_{k=1}^{n}\frac{1}{2k-1} = -\gamma + H_{n-1/2}, \quad (18)$$

where H_n is a HARMONIC NUMBER. At rational arguments, $\psi_0(p/q)$ is given by GAUSS'S DIGAMMA THEOREM.

Sums and differences of $\psi_1(r/s)$ for small integral r and s can be expressed in terms of CATALAN'S CONSTANT and π.

Digimetic

A CRYPTARITHM in which DIGITS are used to represent other DIGITS.

See also CRYPTARITHM

Digit

The number of digits D in an INTEGER n is the number of numbers in some base (usually 10) required to represent it. The numbers 1 to 9 are therefore single digits, while the numbers 10 to 99 are double digits. Terms such as "double-digit inflation" are occasionally encountered, although this particular usage has thankfully not been needed in the U.S. for some time. The number of (base 10) digits in a number n can be calculated as

$$D = \lfloor 1 + \log_{10}|n| \rfloor,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

The number of digits d in the number n represented in base b is given by the *Mathematica* function `DigitCount`$[n, b, d]$, with `DigitCount`$[n, b]$ giving a list of the numbers of each digit in n.

Numbers in base-10 which are divisible by their digits are 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 12, 15, 22, 24, 33, 36, 44, 48, 55, 66, 77, 88, 99, 111, 112, 115, 122, ... (Sloane's A034838). Numbers which are divisible by the sum of their digits are called HARSHAD NUMBERS: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 18, 20, 21, 24, ... (Sloane's A005349). Numbers which are divisible by both their digits and

the sum of their digits are 1, 2, 3, 4, 5, 6, 7, 8, 9, 12, 24, 36, 48, 111, 112, 126, 132, 135, 144, ... (Sloane's A050104). Numbers which are *equal* to (i.e., not just divisible by) the product of their divisors and the sum of their divisors are called SUM-PRODUCT NUMBERS and are given by 1, 135, 144, ... (Sloane's A038369).

b	order	Sloane	Numbers ($\geq b$)

16	nonincreasing	A023771	17, 32, 33, 34, 48, 49, 50, 51, 64, 65, 66, 67, ...
16	decreasing	A023797	32, 33, 48, 49, 50, 64, 65, 66, 67, 80, 81, 82, ...

In HEXADECIMAL, numbers with increasing digits are called METADROMES, those with nondecreasing digits are called PLAINDRONES, those with nonincreasing digits are called NIALPDROMES, and those with decreasing digits are called KATADROMES.

The count of numbers with strictly increasing digits in base-b is 2^{b-1}, and the number with strictly decreasing digits is 2^{b-1}.

Digit Series

Let $s_b(n)$ be the sum of the base-b digits of n, which can be implemented in *Mathematica* as

```
s[n_, b_] := Plus @@ IntegerDigits[n, b]
```

Then

$$\sum_{n=1}^{\infty}\frac{s_b(n)}{n(n+1)} = \frac{b}{b-1}\ln b, \tag{1}$$

the $b=2$ case of which was given in the 1981 Putnam competition (Allouche 1992). In addition,

$$\sum_{n=1}^{\infty} s_2\frac{2n+1}{n^2(n+1)^2} = \frac{\pi^2}{9} \tag{2}$$

$$\sum_{n=2}^{\infty}[s_2(n)]^2\frac{8n^3+4n^2+n-1}{4n(n^2-1)(4n^2-1)} = \frac{17}{24}+\ln 2 \tag{3}$$

(Allouche 1992, Allouche and Shallit 1992).

Let $u(n)$ be the number of DIGIT BLOCKS of 11 in the binary expansion of n, then

$$\sum_{n=1}^{\infty}\frac{u(n)}{n(n+1)} = \frac{3}{2}\ln 2 - \frac{1}{4}\pi \tag{4}$$

(Allouche 1992).

Digitaddition

Start with an INTEGER n, known as the GENERATOR. Add the SUM of the GENERATOR's digits to obtain the digitaddition n'. A number can have more than one GENERATOR. If a number has no GENERATOR, it is called a SELF NUMBER. The sum of all numbers in a digitaddition series is given by the last term minus the first plus the sum of the DIGITS of the last.

If the digitaddition process is performed on n' to yield *its* digitaddition n'', on n'' to yield n''', etc., a single-digit number, known as the DIGITAL ROOT of n, is eventually obtained. The digital roots of the first few integers are 1, 2, 3, 4, 5, 6, 7, 8, 9, 1, 2, 3, 4, 5, 6, 7, 8, 9, 1, ... (Sloane's A010888).

If the process is generalized so that the kth (instead of first) powers of the digits of a number are repeatedly added, a periodic sequence of numbers is eventually obtained for any given starting number n. If the original number n is equal to the sum of the kth powers of its digits, it is called a NARCISSISTIC NUMBER. If the original number is the smallest number in the eventually periodic sequence of numbers in the repeated k-digitadditions, it is called a RECURRING DIGITAL INVARIANT. Both NARCISSISTIC NUMBERS and RECURRING DIGITAL INVARIANTS are relatively rare.

The only possible periods for repeated 2-digitadditions are 1 and 8, and the periods of the first few positive integers are 1, 8, 8, 8, 8, 8, 1, 8, 8, 1, ... The possible periods p for n-digitadditions are summarized in the following table, together with digitadditions for the first few integers and the corresponding sequence numbers. Some periods do not show up for a long time. For example, a period-6 10-digitaddition does not occur until the number 266.

n	Sloane	ps	n-Digitadditions
2	Sloane's A031176	1, 8	1, 8, 8, 8, 8, 8, 1, 8, 8, 1, ...
3	Sloane's A031178	1, 2, 3	1, 1, 1, 3, 1, 1, 1, 1, 1, 1, 1, 1, 3, ...

4	Sloane's A031182	1, 2, 7	1, 7, 7, 7, 7, 7, 7, 7, 7, 1, 7, 1, 7, 7, ...
5	Sloane's A031186	1, 2, 4, 6, 10, 12, 22, 28	1, 12, 22, 4, 10, 22, 28, 10, 22, 1, ...
6	Sloane's A031195	1, 2, 3, 4, 10, 30	1, 10, 30, 30, 30, 10, 10, 10, 3, 1, 10, ...

Digital Root

Consider the process of taking a number, adding its DIGITS, then adding the DIGITS of numbers derived from it, etc., until the remaining number has only one DIGIT. The number of additions required to obtain a single DIGIT from a number n is called the ADDITIVE PERSISTENCE of n, and the DIGIT obtained is called the digital root of n.

For example, the sequence obtained from the starting number 9876 is (9876, 30, 3), so 9876 has an ADDITIVE PERSISTENCE of 2 and a digital root of 3. The digital roots of the first few integers are 1, 2, 3, 4, 5, 6, 7, 8, 9, 1, 2, 3, 4, 5, 6, 7, 9, 1, ... (Sloane's A010888). The digital root of an INTEGER n can therefore be computed without actually performing the iteration using the simple congruence formula

$$\begin{cases} n \pmod 9 & n \not\equiv 0 \pmod 9 \\ 9 & n \equiv 0 \pmod 9). \end{cases}$$

Digit-Extraction Algorithm

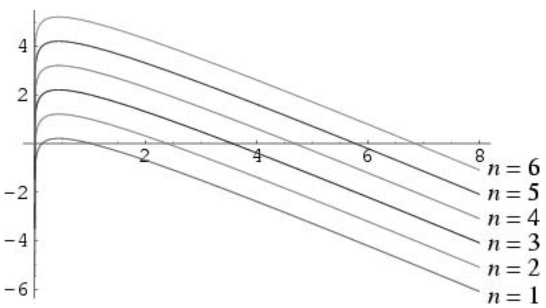
An algorithm which allows digits of a given number to be calculated without requiring the computation of earlier digits. The BAILEY-BORWEIN-PLOUFFE ALGORITHM for PI is the best-known such algorithm, but an algorithm also exists for E.

See also BAILEY-BORWEIN-PLOUFFE ALGORITHM

Digit-Shifting Constants

Given a REAL NUMBER x, find the powers of a base b that will shift the digits of x a number of places n to the left. This is equivalent to solving

$$b^x = b^n x \qquad (1)$$



or

$$x = n + \log_b x. \quad (2)$$

The solution is given by

$$x = -\frac{W(-b^{-n}\ln b)}{\ln b}, \quad (3)$$

where $W(x)$ is LAMBERT'S W-FUNCTION.

The above plot shows $\log_b x + n - x$ for $b = 10$ and small values of n. As can be seen, there are two distinct solutions, corresponding to two different BRANCHES of $W(x)$ in (3). For $n = 1$, 2, ..., these solutions are approximately given by 0.137129, 0.0102386, 0.00100231, 0.000100023, 0.0000100002, ..., and 1, 2.37581, 3.55026, 4.66925, 5.76046, ..., respectively. For example,

$$10^{0.0102385\ldots} = 1.02385\ldots \quad (4)$$

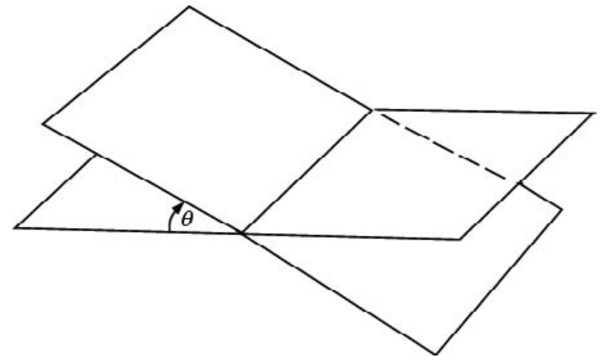
and

$$10^{2.37581\ldots} = 237.581\ldots \quad (5)$$

See also BASE (NUMBER), DIGIT, LOGARITHM

Digon

digon



The DEGENERATE POLYGON (corresponding to a LINE SEGMENT) with SCHLÄFLI SYMBOL {2}.

See also LINE SEGMENT, POLYGON, TRIGONOMETRY VALUES PI/2

Digraph

DIRECTED GRAPH

Dihedral Angle

The ANGLE θ between two PLANES. The dihedral angle between the planes

$$A_1 x + B_1 y + C_1 z + D_1 = 0 \quad (1)$$

$$A_2 x + B_2 y + C_2 z + D_2 = 0 \quad (2)$$

which have normal vectors $\mathbf{N}_1 = (A_1, B_1, C_1)$ and $\mathbf{N}_2 = (A_2, B_2, C_2)$ is simply given via the DOT PRODUCT of the normals,

$$\cos\theta = \mathbf{N}_1 \cdot \mathbf{N}_2$$

$$= \frac{A_1 A_2 + B_1 B_2 + C_1 C_2}{\sqrt{A_1^2 + B_1^2 + C_1^2}\sqrt{A_2^2 + B_2^2 + C_2^2}}. \quad (3)$$

The dihedral angle between planes in a general TETRAHEDRON is closely connected with the face areas via a generalization of the LAW OF COSINES.

See also ANGLE, PLANE, TETRAHEDRON, TRIHEDRON, VERTEX ANGLE

Dihedral Prime

A number n such that the "LED representation" of n (i.e., the arrangement of horizonal and vertical lines seen on a digital clock or pocket calculator), n upside down, n in a mirror, and n upside-down-and-in-a-mirror are all primes. The digits of n are therefore restricted to 0, 1, 2, 5, and 8. The first few dihedral

primes are 2, 11, 101, 181, 1181, 1811, 18181, 108881, 110881, 118081, 120121, ... (Sloane's A038136).

Dijkstra Tree

The shortest path-spanning TREE from a VERTEX of a GRAPH.

Dijkstra's Algorithm

An ALGORITHM for finding a GRAPH GEODESIC, i.e., the shortest path between two VERTICES in a GRAPH. It functions by constructing a shortest-path tree from the initial vertex to every other vertex in the graph. The algorithm is implemented as `Dijkstra[g]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

Dilation

A SIMILARITY TRANSFORMATION which transforms each line to a PARALLEL line whose length is a fixed multiple of the length of the original line. The simplest dilation is therefore a TRANSLATION, and any dilation that is not merely a TRANSLATION is called a CENTRAL DILATION. Two triangles related by a CENTRAL DILATION are said to be PERSPECTIVE TRIANGLES because the lines joining corresponding vertices CONCUR. A dilation corresponds to an EXPANSION plus a TRANSLATION.

Dilative Rotation

SPIRAL SIMILARITY

Dilcher's Formula

$$\sum_{1\le k\le n}\binom{n}{k}\frac{(-1)^{k-1}}{k^m} = \sum_{1\le i_1\le i_2\le\ldots\le i_m\le n}\frac{1}{i_1 i_2\cdots i_m}, \qquad (1)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT (Dilcher 1995, Flajolet and Sedgewick 1995, Prodinger 2000). An inverted version is given by

$$\sum_{1\le k\le n}\binom{n}{k}(-1)^{k-1}\sum_{1\le i_1\le i_2\le\ldots\le i_m=k}\frac{1}{i_1 i_2\cdots i_m} = \sum_{1\le k\le n}\frac{1}{k^m}=H_n^{(m)}, \qquad (2)$$

where $H_n^{(k)}$ is a HARMONIC NUMBER of order m (Hernández 1999, Prodinger 2000). A q-ANALOG of (1) is given by

$$\sum_{1\le k\le n}\begin{bmatrix}n\\k\end{bmatrix}_q(-1)^{k-1}\frac{q^{\binom{k+1}{2}+(m-1)k}}{(1-q^k)^m} = \sum_{1\le i_1\le i_2\le\ldots\le i_m\le n}\frac{q^{i_1}}{1-q^{i_1}}\cdots\frac{q^{i_m}}{1-q^{i_m}}, \qquad (3)$$

where

$$\begin{bmatrix}n\\k\end{bmatrix}_q=\frac{(q;q)_n}{(q;q)_k(q;q)_{n-k}} \qquad (4)$$

is a GAUSSIAN POLYNOMIAL (Prodinger 2000).

Dilemma

Informally, a situation in which a decision must be made from several alternatives, none of which is obviously the optimal one. In formal LOGIC, a dilemma is a specific type of argument using two conditional statements which may take the form of a CONSTRUCTIVE DILEMMA or a DESTRUCTIVE DILEMMA.

See also CONSTRUCTIVE DILEMMA, DESTRUCTIVE DILEMMA, MONTY HALL PROBLEM, PARADOX, PRISONER'S DILEMMA

Dilogarithm

A special case of the POLYLOGARITHM $\mathrm{Li}_n(z)$ for $n=2$. It is denoted $\mathrm{Li}_2(z)$, or sometimes $\mathrm{L}_2(z)$. The notation $\mathrm{Li}_2(x)$ for the dilogarithm is unfortunately similar to that for the LOGARITHMIC INTEGRAL $\mathrm{Li}(x)$. The dilogarithm can be defined by the sum

$$\mathrm{Li}_2(z)=\sum_{k=1}^{\infty}\frac{z^k}{k^2} \tag{1}$$

or the integral

$$\mathrm{Li}_2(z)\equiv\int_z^0\frac{\ln(1-t)dt}{t}. \tag{2}$$

There are also two different commonly encountered normalizations for the $\mathrm{Li}_2(z)$ function, both denoted $L(z)$, and one of which is known as the ROGERS L-FUNCTION.

The major functional equations for the dilogarithm are given by

$$\mathrm{Li}_2(x)+\mathrm{Li}_2(-x)=\frac{1}{2}\mathrm{Li}_2\left(x^2\right) \tag{3}$$

$$\mathrm{Li}_2(1-x)+\mathrm{Li}_2\left(1-x^{-1}\right)=-\frac{1}{2}(\ln x)^2 \tag{4}$$

$$\mathrm{Li}_2(x)+\mathrm{Li}_2(1-x)=\frac{1}{6}\pi^2-(\ln x)\ln(1-x) \tag{5}$$

$$\mathrm{Li}_2(-x)-\mathrm{Li}_2(1-x)+\frac{1}{2}\mathrm{Li}_2\left(1-x^2\right)$$

$$=-\frac{1}{12}\pi^2-(\ln x)\ln(x+1). \tag{6}$$

A complete list of $\mathrm{Li}_2(x)$ which can be evaluated in closed form is given by

$$\mathrm{Li}_2(-1)=-\frac{1}{12}\pi^2 \tag{7}$$

$$\mathrm{Li}_2(0)=0 \tag{8}$$

$$\mathrm{Li}_2\left(\frac{1}{2}\right)=\frac{1}{12}\pi^2-\frac{1}{2}(\ln 2)^2 \tag{9}$$

$$\mathrm{Li}_2(1)=\frac{1}{6}\pi^2 \tag{10}$$

$$\mathrm{Li}_2(-\phi)=-\frac{1}{10}\pi^2-(\ln\phi)^2 \tag{11}$$

$$=-\frac{1}{10}\pi^2-\left(\mathrm{csch}^{-1}\,2\right)^2 \tag{12}$$

$$\mathrm{Li}_2(-\phi^{-1})=-\frac{1}{15}\pi^2+\frac{1}{2}(\ln\phi)^2 \tag{13}$$

$$=-\frac{1}{15}\pi^2+\frac{1}{2}\left(\mathrm{csch}^{-1}\,2\right)^2 \tag{14}$$

$$\mathrm{Li}\left(\phi^{-2}\right)=\frac{1}{15}\pi^2-(\ln\phi)^2 \tag{15}$$

$$=\frac{1}{15}\pi^2-\left(\mathrm{csch}^{-1}\,2\right)^2 \tag{16}$$

$$\mathrm{Li}\left(\phi^{-1}\right)=\frac{1}{10}\pi^2-(\ln\phi)^2 \tag{17}$$

$$=\frac{1}{10}\pi^2-\left(\mathrm{csch}^{-1}\,2\right)^2, \tag{18}$$

where ϕ is the GOLDEN RATIO (Lewin 1981, Borwein *et al.* 1998).

There are several remarkable identities involving the DILOGARITHM function. Ramanujan gave the identities

$$\mathrm{Li}_2\left(\frac{1}{3}\right)-\frac{1}{6}\mathrm{Li}_2\left(\frac{1}{9}\right)=\frac{1}{18}\pi^2-\frac{1}{6}(\ln 3)^2 \tag{19}$$

$$\mathrm{Li}_2\left(-\frac{1}{2}\right)+\frac{1}{5}\mathrm{Li}_2\left(\frac{1}{9}\right) =-\frac{1}{18}\pi^2+\ln 2\ln 3-\frac{1}{2}(\ln 2)^2-\frac{1}{3}(\ln 3)^2 \tag{20}$$

$$\mathrm{Li}_2\left(\frac{1}{4}\right)+\frac{1}{3}\mathrm{Li}_2\left(\frac{1}{9}\right) =\frac{1}{18}\pi^2+2\ln 2\ln 3-2(\ln 2)^2-\frac{2}{3}(\ln 3)^2 \tag{21}$$

$$\mathrm{Li}_2\left(-\frac{1}{3}\right)-\frac{1}{3}\mathrm{Li}_2\left(\frac{1}{9}\right)=-\frac{1}{18}\pi^2+\frac{1}{6}(\ln 3)^2 \tag{22}$$

$$\mathrm{Li}_2\left(-\frac{1}{8}\right)+\mathrm{Li}_2\left(\frac{1}{9}\right)=-\frac{1}{2}\left(\ln\frac{9}{8}\right)^2 \tag{23}$$

$$\mathrm{Li}_2\left(\frac{1}{2}\left(\sqrt{5}-1\right)\right)=\frac{1}{10}\pi^2-\left[\ln\left(\frac{1}{2}\left(1+\sqrt{5}\right)\right)\right]^2 \tag{24}$$

(Berndt 1994, Gordon and McIntosh 1997), and Bailey *et al.* show that

$$\pi^2=36\mathrm{Li}_2\left(\frac{1}{2}\right)-36\mathrm{Li}_2\left(\frac{1}{4}\right)-12\mathrm{Li}_2\left(\frac{1}{8}\right)+6\mathrm{Li}_2\left(\frac{1}{64}\right) \tag{25}$$

$$12\mathrm{Li}_2\left(\frac{1}{2}\right)=\pi^2-6(\ln 2)^2 \tag{26}$$

Dilworth's Lemma

The width of a set P is equal to the minimum number of chains needed to cover P. Equivalently, if a set P of $ab+1$ elements is partially ordered, then P contains a chain of size $a+1$ or an antichain of size $b+1$. Letting N be the cardinality of P, W the width, and L the length, this last statement says $N \leq LW$. Dilworth's lemma is a generalization of the Erdos-Szekeres Theorem. Ramsey's Theorem generalizes Dilworth's lemma.

Dilworth's Theorem

Dilworth's Lemma

Dimension

The dimension of an object is a topological measure of the size of its covering properties. Roughly speaking, it is the number of coordinates needed to specify a point on the object. For example, a rectangle is two-dimensional, while a cube is three-dimensional. The dimension of an object is sometimes also called its "dimensionality."

The prefix "hyper-" is usually used to refer to the 4- (and higher-) dimensional analogs of 3-dimensional objects, e.g. hypercube, hyperplane.

The notion of dimension is important in mathematics because it gives a precise parameterization of the conceptual or visual complexity of any geometric object. In fact, the concept can even be applied to abstract objects which cannot be directly visualized. For example, the notion of time can be considered as one-dimensional, since it can be thought of as consisting of only "now," "before" and "after." Since

"before" and "after," regardless of how far back or how far into the future they are, are extensions, time is like a line, a 1-dimensional object.

To see how lower and higher dimensions relate to each other, take any geometric object (like a POINT, LINE, CIRCLE, PLANE, etc.), and "drag" it in an opposing direction (drag a POINT to trace out a LINE, a LINE to trace out a box, a CIRCLE to trace out a CYLINDER, a DISK to a solid CYLINDER, etc.). The result is an object which is qualitatively "larger" than the previous object, "qualitative" in the sense that, regardless of how you drag the original object, you always trace out an object of the same "qualitative size." The POINT could be made into a straight LINE, a CIRCLE, a HELIX, or some other CURVE, but all of these objects are qualitatively of the same dimension. The notion of dimension was invented for the purpose of measuring this "qualitative" topological property.

Finite collections of objects (e.g., points in space) are considered 0-dimensional. Objects that are "dragged" versions of 0-dimensional objects are then called 1-dimensional. Similarly, objects which are dragged 1-dimensional objects are 2-dimensional, and so on. Dimension is formalized in mathematics as the intrinsic dimension of a TOPOLOGICAL SPACE. This dimension is called the LEBESGUE COVERING DIMENSION (also known simply as the TOPOLOGICAL DIMENSION). The archetypal example is EUCLIDEAN n-space $\mathbb{R}^n$, which has topological dimension n. The basic ideas leading up to this result (including the DIMENSION INVARIANCE THEOREM, DOMAIN INVARIANCE THEOREM, and LEBESGUE COVERING DIMENSION) were developed by Poincaré, Brouwer, Lebesgue, Urysohn, and Menger.

There are several branchings and extensions of the notion of topological dimension. Implicit in the notion of the LEBESGUE COVERING DIMENSION is that dimension, in a sense, is a measure of how an object fills space. If it takes up a lot of room, it is higher dimensional, and if it takes up less room, it is lower dimensional. HAUSDORFF DIMENSION (also called FRACTAL DIMENSION) is a fine tuning of this definition that allows notions of objects with dimensions other than INTEGERS. FRACTALS are objects whose HAUSDORFF DIMENSION is different from their TOPOLOGICAL DIMENSION.

The concept of dimension is also used in ALGEBRA, primarily as the dimension of a VECTOR SPACE over a FIELD. This usage stems from the fact that VECTOR SPACES over the reals were the first VECTOR SPACES to be studied, and for them, their topological dimension can be calculated by purely algebraic means as the CARDINALITY of a maximal linearly independent subset. In particular, the dimension of a SUBSPACE of $\mathbb{R}^n$ is equal to the number of LINEARLY INDEPENDENT VECTORS needed to generate it (i.e., the number of VECTORS in its BASIS). Given a transformation A of $\mathbb{R}^n$,

$$\dim[\mathrm{Range}(A)] + \dim[\mathrm{Null}(A)] = \dim(\mathbb{R}^n).$$

Dimension Axiom

One of the EILENBERG-STEENROD AXIOMS. Let X be a single point space. $H_n(X) = 0$ unless $n = 0$, in which case $H_0(X) = 0$ where G are some GROUPS. The H_0 are called the COEFFICIENTS of the HOMOLOGY THEORY $H(\cdot)$.

See also EILENBERG-STEENROD AXIOMS, HOMOLOGY (TOPOLOGY)

Dimension Invariance Theorem

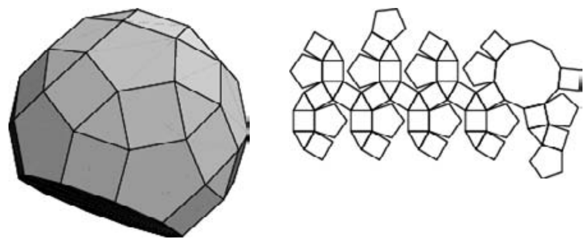
$\mathbb{R}^n$ is HOMEOMORPHIC to $\mathbb{R}^m$ IFF $n = m$. This theorem was first proved by Brouwer.

See also DOMAIN INVARIANCE THEOREM

Dimensionality

DIMENSION

Dimensionality Theorem



For a FINITE GROUP of h elements with an n_ith dimensional ith irreducible representation,

$$\sum_i n_i^2 = h$$

Dini's Surface

A surface of constant negative curvature obtained by twisting a pseudosphere and given by the parametric equations

$$x = a \cos u \sin v \tag{1}$$

$$y = a \sin u \sin v \tag{2}$$

$$z = a\left\{\cos v + \ln\left[\tan\left(\frac{1}{2}v\right)\right]\right\} + bu. \tag{3}$$

The above figure corresponds to $a = 1$, $b = 0.2$, $u \in [0, 4\pi]$, and $v \in (0, 2]$.

The coefficients of the first fundamental form are

$$E = \frac{1}{2}[a^2 + 2b^2 - a^2 \cos(2v)] \tag{4}$$

$$F = ab \cos v \cot v \tag{5}$$

$$G = a^2 \cot^2 v, \tag{6}$$

the coefficients of the second fundamental form are

$$e = -\frac{a^2 \cos v \sin v}{\sqrt{a^2 + b^2}} \tag{7}$$

$$f = \frac{ab \cos v}{\sqrt{a^2 + b^2}} \tag{8}$$

$$g = \frac{a^2 \cot v}{\sqrt{a^2 + b^2}}, \tag{9}$$

and the area element is

$$dA = a\sqrt{a^2 + b^2} \cos v. \tag{10}$$

The Gaussian and mean curvatures are given by

$$K = -\frac{1}{a^2 + b^2} \tag{11}$$

$$H = -\frac{\cot(2v)}{\sqrt{a^2 + b^2}}. \tag{12}$$

Dini's Test

A test for the convergence of Fourier series. Let

$$\phi_x(t) \equiv f(x + t) + f(x - t) - 2f(x),$$

then if

$$\int_0^\pi \frac{|\phi_x(t)|dt}{t}$$

is FINITE, the FOURIER SERIES converges to $f(x)$ at x.

Dinitz Problem

Given any assignment of n-element sets to the n^2 locations of a square $n \times n$ array, is it always possible to find a PARTIAL LATIN SQUARE? The fact that such a PARTIAL LATIN SQUARE can always be found for a 2×2 array can be proven analytically, and techniques were developed which also proved the existence for 4×4 and 6×6 arrays. However, the general problem eluded solution until it was answered in the affirmative by Galvin in 1993 using results of Janssen (1993ab) and F. Maffray.

Diocles's Cissoid

CISSOID OF DIOCLES

Diophantine Equation

An equation in which only INTEGER solutions are allowed. HILBERT'S 10TH PROBLEM asked if a technique for solving a general Diophantine existed. A general method exists for the solution of first degree Diophantine equations. However, the impossibility of obtaining a general solution was proven by Julia Robinson and Martin Davis in 1970, following proof of the result that the relation $n = F_{2m}$ (where F_{2m} is a FIBONACCI NUMBER) is Diophantine by Yuri Matiyasevich (Matiyasevich 1970, Davis 1973, Davis and Hersh 1973, Davis 1982, Matiyasevich 1993). More specifically, Matiyasevich showed that there is a polynomial P in n, m, and a number of other variables x, y, z, ... having the property that $n = F_{2m}$ IFF there exist integers x, y, z, ... such that $P(n, m, x, y, z, \ldots) = 0$..

Jones and Matiyasevich (1982) proved that no ALGORITHMS can exist to determine if an arbitrary Diophantine equation in nine variables has solutions. As a consequence of this result, it can be proved that there does not exists a general algorithm for solving a QUARTIC DIOPHANTINE EQUATION, although the algorithm for constructing such an unsolvable quartic Diophantine equation can require arbitrarily many variables (Matiyasevich 1993).

Ogilvy and Anderson (1988) give a number of Diophantine equations with known and unknown solutions.

A linear Diophantine equation (in two variables) is an equation of the general form

$$ax + by = c, \tag{1}$$

where solutions are sought with a, b, and c INTEGERS. Such equations can be solved completely, and the first known solution was constructed by Brahmagupta. Consider the equation

$$ax + by = 1. \tag{2}$$

Now use a variation of the EUCLIDEAN ALGORITHM, letting $a = r_1$ and $b = r_2$

$$r_1 = q_1 r_2 + r_3 \tag{3}$$

$$r_2 = q_2 r_3 + r_4 \tag{4}$$

$$r_{n-3} = q_{n-3} r_{n-2} + r_{n-1} \tag{5}$$

$$r_{n-2} = q_{n-2} r_{n-1} + 1. \tag{6}$$

Starting from the bottom gives

$$1 = r_{n-2} - q_{n-2} r_{n-1} \tag{7}$$

$$r_{n-1} = r_{n-3} - q_{n-3} r_{n-2}, \tag{8}$$

so

$$\begin{aligned} 1 &= r_{n-2} - q_{n-2}(r_{n-3} - q_{n-3} r_{n-2}) \\ &= -q_{n-2} r_{n-3} + (1 - q_{n-2} q_{n-3}) r_{n-2}. \end{aligned} \tag{9}$$

Continue this procedure all the way back to the top.

Take as an example the equation

$$1027x + 712y = 1. \tag{10}$$

Proceed as follows.

$$\begin{array}{rrl|rrr} 1027 = & 712\cdot 1 + 315 & \mid & 1 = -165\cdot & 1027 + 238\cdot 712 & \uparrow \\ 712 = & 315\cdot 2 + 82 & \mid & 1 = 73\cdot & 712 - 165\cdot 315 & \mid \\ 315 = & 82\cdot 3 + 69 & \mid & 1 = -19\cdot & 315 + 73\cdot 82 & \mid \\ 82 = & 69\cdot 1 + 13 & \mid & 1 = 16\cdot & 82 - 19\cdot 69 & \mid \\ 69 = & 13\cdot 5 + 4 & \mid & 1 = -3\cdot & 69 + 16\cdot 13 & \mid \\ 13 = & 4\cdot 3 + 1 & \downarrow & 1 = 1\cdot & 13 - 3\cdot 4 & \mid \\ & & & 1 = 0\cdot & 4 + 1\cdot 1 & \mid \end{array}$$

The solution is therefore $x = -165$, $y = 238$. The

above procedure can be simplified by noting that the two left-most columns are offset by one entry and alternate signs, as they must since

$$1 = -A_{i+1}r_i + A_i r_{i+1} \tag{11}$$

$$r_{i+1} = r_{i-1} - r_i q_{i-1} \tag{12}$$

$$1 = A_i r_{i-1} - (A_i q_{i-1} + A_{i+1}), \tag{13}$$

so the COEFFICIENTS of r_{i-1} and r_{i+1} are the same and

$$A_{i-1} = -(A_i q_{i-1} + A_{i+1}). \tag{14}$$

Repeating the above example using this information therefore gives

$$\begin{array}{rcl|rcl}
1027 = & 712 \cdot 1 + 315 & & 1 = & -165 \cdot & 1027 + 238 \cdot 712 \uparrow \\
712 = & 315 \cdot 2 + 82 & & 1 = & 73 \cdot & 712 - 165 \cdot 315 \\
315 = & 82 \cdot 3 + 69 & & 1 = & -19 \cdot & 315 + 73 \cdot 82 \\
82 = & 69 \cdot 1 + 13 & & 1 = & 16 \cdot & 82 - 19 \cdot 69 \\
69 = & 13 \cdot 5 + 4 & & 1 = & -3 \cdot & 69 + 16 \cdot 13 \\
13 = & 4 \cdot 3 + 1 & \downarrow & 1 = & 1 \cdot & 13 - 3 \cdot 4 \\
 & & & 1 = & 0 \cdot & 4 + 1 \cdot 1
\end{array}$$

and we recover the above solution.

Call the solutions to

$$ax + by = 1 \tag{15}$$

x_0 and y_0. If the signs in front of ax or by are NEGATIVE, then solve the above equation and take the signs of the solutions from the following table:

equation	x	y
$ax + by = 1$	x_0	y_0
$ax - by = 1$	x_0	$-y_0$
$-ax + by = 1$	$-x_0$	y_0
$-ax - by = 1$	$-x_0$	$-y_0$

In fact, the solution to the equation

$$ax - by = 1 \tag{16}$$

is equivalent to finding the CONTINUED FRACTION for a/b, with a and b RELATIVELY PRIME (Olds 1963). If there are n terms in the fraction, take the $(n-1)$th convergent p_{n-1}/q_{n-1}. But

$$p_n q_{n-1} - p_{n-1} q_n = (-1)^n, \tag{17}$$

so one solution is $x_0 = (-1)^n q_{n-1}$, $y_0 = (-1)^n p_{n-1}$, with a general solution

$$x = x_0 + kb \tag{18}$$

$$y = y_0 + ka \tag{19}$$

with k an arbitrary INTEGER. The solution in terms of smallest POSITIVE INTEGERS is given by choosing an appropriate k.

Now consider the general first-order equation OF THE FORM

$$ax + by = c. \tag{20}$$

The GREATEST COMMON DIVISOR $d \equiv \mathrm{GCD}(a, b)$ can be divided through yielding

$$a'x + b'y = c', \tag{21}$$

where $a' \equiv a/d$, $b' \equiv b/d$, and $c' \equiv c/d$. If $d \nmid c$, then c' is not an INTEGER and the equation cannot have a solution in INTEGERS. A necessary and sufficient condition for the general first-order equation to have solutions in INTEGERS is therefore that $d|c$. If this is the case, then solve

$$a'x + b'y = 1 \tag{22}$$

and multiply the solutions by c', since

$$a'(c'x) + b'(c'y) = c'. \tag{23}$$

D. Wilson has compiled a list of the smallest nth POWERS which are the sums of n *distinct* smaller nth POWERS. The first few are 3, 5, 6, 15, 12, 25, 40, ...(Sloane's A030052):

$$3^1 = 1^1 + 2^1$$
$$5^2 = 3^2 + 4^2$$
$$6^3 = 3^3 + 4^3 + 5^3$$
$$15^4 = 4^4 + 6^4 + 8^4 + 9^4 + 14^4$$
$$12^5 = 4^5 + 5^5 + 6^5 + 7^5 + 9^5 + 11^5$$
$$\begin{aligned}25^6 = {} & 1^6 + 2^6 + 3^6 + 5^6 + 6^6 + 7^6 + 8^6 + 9^6 + 10^6 \\ & + 12^6 + 13^6 + 15^6 + 16^6 + 17^6 + 18^6 + 23^6\end{aligned}$$
$$\begin{aligned}40^7 = {} & 1^7 + 3^7 + 5^7 + 9^7 + 12^7 + 14^7 + 16^7 + 17^7 \\ & + 18^7 + 20^7 + 21^7 + 22^7 + 25^7 + 28^7 + 39^7\end{aligned}$$
$$\begin{aligned}84^8 = {} & 1^8 + 2^8 + 3^8 + 5^8 + 7^8 + 9^8 + 10^8 + 11^8 \\ & + 12^8 + 13^8 + 14^8 + 15^8 + 16^8 + 17^8 + 18^8 \\ & + 19^8 + 21^8 + 23^8 + 24^8 + 25^8 + 26^8 + 27^8 \\ & + 29^8 + 32^8 + 33^8 + 35^8 + 37^8 + 38^8 + 39^8 \\ & + 41^8 + 42^8 + 43^8 + 45^8 + 46^8 + 47^8 + 48^8 \\ & + 49^8 + 51^8 + 52^8 + 53^8 + 57^8 + 58^8 + 59^8 \\ & + 61^8 + 63^8 + 69^8 + 73^8\end{aligned}$$
$$\begin{aligned}47^9 = {} & 1^9 + 2^9 + 4^9 + 7^9 + 11^9 + 14^9 + 15^9 + 18^9 \\ & + 26^9 + 27^9 + 30^9 + 31^9 + 32^9 + 33^9 \\ & + 36^9 + 38^9 + 39^9 + 43^9\end{aligned}$$

Diophantine Equation—10th Powers

The 10.1.2 equation

$$A^{10} = B^{10} + C^{10} \tag{1}$$

is a special case of FERMAT'S LAST THEOREM with $n = 10$, and so has no solution. The smallest 10.1.15 solution is

$$100^{10} + 94^{10} + 91^{10} + 2\cdot 77^{10} + 76^{10} + 63^{10} + 62^{10} + 52^{10}$$
$$+45^{10} + 35^{10} + 33^{10} + 16^{10} + 10^{10} + 1^{10} = 108^{10} \tag{2}$$

(J.-C. Meyrignac 1999, PowerSum). The smallest 10.1.22 solution is

$$33^{10} = 2\cdot 30^{10} + 2\cdot 26^{10} + 23^{10} + 21^{10} + 19^{10} + 18^{10}$$
$$+2\cdot 13^{10} + 2\cdot 12^{10} + 5\cdot 10^{10} + 2\cdot 9^{10} + 7^{10} + 6^{10} + 3^{10} \tag{3}$$

(Ekl 1998). The smallest 10.1.23 solution is

$$5\cdot 1^{10} + 2^{10} + 3^{10} + 6^{10} + 6\cdot 7^{10} + 4\cdot 9^{10}$$
$$+10^{10} + 2\cdot 12^{10} + 13^{10} + 14^{10} = 15^{10} \tag{4}$$

(Lander *et al.* 1967).

The smallest 10.2.13 solution is

$$51^{10} + 32^{10} = 49^{10} + 43^{10} + 41^{10} + 37^{10} + 28^{10} + 26^{10}$$
$$+25^{10} + 15^{10} + 10^{10} + 109^{10} + 5^{10} + 3^{10}. \tag{5}$$

The smallest 10.2.15 solution is

$$35^{10} + 3^{10} = 33^{10} + 32^{10} + 24^{10} + 21^{10} + 2\cdot 20^{10}$$
$$+3\cdot 13^{10} + 12^{10} + 11^{10} + 9^{10} + 7^{10} + 2\cdot 1^{10} \tag{6}$$

(Ekl 1998). The smallest 10.2.19 solution is

$$5\cdot 2^{10} + 5^{10} + 6^{10} + 10^{10} + 6\cdot 11^{10}$$

$$+2\cdot 12^{10}+3\cdot 15^{10}=9^{10}+17^{10} \quad (7)$$

(Lander *et al.* 1967).

The smallest 10.3.13 solution is

$$46^{10}+32^{10}+22^{10}$$
$$=43^{10}+43^{10}+27^{10}+26^{10}+17^{10}+16^{10}$$
$$+12^{10}+9^{10}+9^{10}+6^{10}+4^{10}+3^{10}+3^{10}. \quad (8)$$

The smallest 10.3.14 solution is

$$30^{10}+28^{10}+4^{10}=31^{10}+23^{10}+2\cdot 20^{10}+2\cdot 17^{10}$$
$$+16^{10}+10^{10}+3\cdot 9^{10}+5^{10}+2\cdot 2^{10} \quad (9)$$

(Ekl 1998). The smallest 10.3.24 solution is

$$1^{10}+2^{10}+3^{10}+10\cdot 4^{10}+7^{10}+7\cdot 8^{10}$$
$$+10^{10}+12^{10}+16^{10}=11^{10}+2\cdot 15^{10} \quad (10)$$

(Lander *et al.* 1967).

The 10.4.12 equation has solution

$$51^{10}+49^{10}+43^{10}+39^{10}+29^{10}+28^{10}+2\cdot 17^{10}$$
$$+16^{10}+13^{10}+7^{10}+4^{10}=53^{10}+244^{10}+22^{10} \quad (11)$$

(E. Bainville 1999, PowerSum). The smallest 10.4.15 solution is

$$4\cdot 23^{10}=26^{10}+5\cdot 18^{10}+3\cdot 17^{10}+15^{10}+12^{10}+6^{10}$$
$$+3\cdot 4^{10} \quad (12)$$

(Ekl 1998). The smallest 10.4.23 solution is

$$5\cdot 1^{10}+2\cdot 2^{10}+2\cdot 3^{10}+4^{10}+4\cdot 6^{10}+3.7^{10}+8^{10}$$
$$+2\cdot 10^{10}+2\cdot 14^{10}+15^{10}=3\cdot 11^{10}+16^{10} \quad (13)$$

(Lander *et al.* 1967).

The smallest 10.5.16 solutions are

$$4\cdot 1^{10}+2^{10}+2\cdot 4^{10}+6^{10}+2\cdot 12^{10}$$
$$+5\cdot 13^{10}+15^{10}=2\cdot 3^{10}+8^{10}+14^{10}+16^{10} \quad (14)$$
$$20^{10}+11^{10}+8^{10}+3^{10}+1^{10}=2\cdot 18^{10}+17^{10}$$
$$+16^{10}+10^{10}+2\cdot 7^{10}+6\cdot 4^{10}+2\cdot 2^{10} \quad (15)$$

(Lander *et al.* 1967, Ekl 1998).

The smallest 10.6.6 solution is

$$95^{10}+71^{10}+32^{10}+28^{10}+25^{10}+16^{10}$$
$$=92^{10}+85^{10}+34^{10}+34^{10}+23^{10}+5^{10}. \quad (16)$$

The smallest 10.6.16 solution is

$$18^{10}+12^{10}+11^{10}+10^{10}+3^{10}+2^{10}$$
$$=17^{10}+16^{10}+4\cdot 13^{10}+4\cdot 7^{10}+4\cdot 6^{10}+5^{10}+4^{10} \quad (17)$$

(Ekl 1998). The smallest 10.6.27 solution is

$$1^{10}+4\cdot 3^{10}+2\cdot 4^{10}+2\cdot 5^{10}+7\cdot 6^{10}$$
$$+9\cdot 7^{10}+10^{10}+13^{10}=2\cdot 2^{10}+8^{10}+11^{10}+2\cdot 12^{10} \quad (18)$$

(Lander *et al.* 1967).

The smallest 10.7.7 solutions are

$$38^{10}+33^{10}+26^{10}+26^{10}+15^{10}+8^{10}+1^{10}$$
$$=36^{10}+35^{10}+32^{10}+29^{10}+24^{10}+23^{10}+22^{10} \quad (19)$$
$$68^{10}+61^{10}+55^{10}+32^{10}+31^{10}+28^{10}+1^{10}$$
$$=67^{10}+64^{10}+49^{10}+44^{10}+23^{10}+20^{10}+17^{10} \quad (20)$$

(Lander *et al.* 1967, Ekl 1998).

Diophantine Equation—2nd Powers

A general quadratic Diophantine equation in two variables x and y is given by

$$ax^2+cy^2=k, \quad (1)$$

where a, c, and k are specified (positive or negative) integers and x and y are unknown integers satisfying the equation whose values are sought. The slightly more general second-order equation

$$ax^2+bxy+cy^2=k \quad (2)$$

is one of the principal topics in Gauss's *Disquisitiones arithmeticae*. According to Itô (1987), equation (2) can be solved completely using solutions to the PELL EQUATION. In particular, all solutions of

$$ax^2+bxy+cy^2=1 \quad (3)$$

are among the CONVERGENTS of the CONTINUED FRACTIONS of the roots of ax^2+bx+c. In *Mathematica* 5.0, solution to the general bivariate quadratic Diophantine equation will be implemented as `Reduce[`*eqn* && `Element[`x | y`, Integers], {`x, y`}]`.

For quadratic Diophantine equations in more than two variables, there exist additional deep results due to C. L. Siegel.

An equation OF THE FORM

$$x^2-Dy^2=1, \quad (4)$$

where D is an INTEGER is a very special type of equation called a PELL EQUATION. Pell equations, as

well as the analogous equation with a minus sign on the right, can be solved by finding the CONTINUED FRACTION for $\sqrt{D}$. The more complicated equation

$$x^2 - Dy^2 = c \tag{5}$$

can also be solved for certain values of c and D, but the procedure is more complicated (Chrystal 1961). However, if a single solution to (5) is known, other solutions can be found using the standard technique for the PELL EQUATION.

The following table summarizes possible representation of primes p of given forms, where x and y are positive integers. No odd primes other than those indicated share these properties (Nagell 1951, p. 188).

form	congruence for p
x^2+y^2	$\equiv 1 \pmod 4$
x^2+2y^2	$\equiv 1, 3 \pmod 8$
x^2+3y^2	$\equiv 1 \pmod 6$
x^2+7y^2	$\equiv 1, 9, 11 \pmod{14}$
$2x^2+3y^2$	$\equiv 5, 11 \pmod{24}$

As a part of the study of WARING'S PROBLEM, it is known that every positive integer is a sum of no more than 4 positive squares ($g(2)=4$; LAGRANGE'S FOUR-SQUARE THEOREM), that every "sufficiently large" integer is a sum of no more than 4 positive squares ($G(2)=4$), and that every integer is a sum of at most 3 signed squares ($eg(2)=3$). If zero is counted as a square, both POSITIVE and NEGATIVE numbers are included, and the order of the two squares is distinguished, Jacobi showed that the number of ways a number can be written as the sum of two squares (the $r_2(n)$ function) is four times the excess of the number of DIVISORS of the form $4x+1$ over the number of DIVISORS OF THE FORM $4x-1$.

In 1769 Euler (1862) noted the identity

$$\alpha b(apr \pm \beta qs)^2 + a\beta(\alpha ps \mp bqr)^2 = (a\alpha p^2 + b\beta q^2)(abr^2 + \alpha\beta s^2), \tag{6}$$

which gives a parametric solution to the equation

$$Ax^2 + By^2 = C \tag{7}$$

for integers A, B, C, x, y with C composite (Dickson 1957, p. 407).

Call a Diophantine equation consisting of finding a sum of m kth POWERS which is equal to a sum of n kth POWERS a "$k.m.n$ equation." The 2.1.2 quadratic Diophantine equation

$$A^2 = B^2 + C^2, \tag{8}$$

corresponds to finding a PYTHAGOREAN TRIPLE (A, B, C) has a well-known general solution (Dickson 1966, pp. 165–70). To solve the equation, note that every PRIME OF THE FORM $4x+1$ can be expressed as the sum of two RELATIVELY PRIME squares in exactly one way. A set of INTEGERS satisfying the 2.1.3 equation

$$A^2 = B^2 + C^2 + D^2 \tag{9}$$

is called a PYTHAGOREAN QUADRUPLE.

Parametric solutions to the 2.2.2 equation

$$A^2 + B^2 = C^2 + D^2 \tag{10}$$

are known (Dickson 1966; Guy 1994, p. 140). To find in how many ways a general number m can be expressed as a sum of two squares, factor it as follows

$$m = 2^{a_0} p_1^{2a_1} \cdots p_n^{2a_n} q_1^{b_1} \cdots q_r^{b_r}, \tag{11}$$

where the ps are primes OF THE FORM $4x-1$ and the qs are primes OF THE FORM $x+1$. If the as are integral, then define

$$B \equiv (2b_1+1)(2b_2+1)\cdots(2b_r+1) - 1. \tag{12}$$

Then m is a sum of two *unequal* squares in

$$N(m) = \begin{cases} 0 \\ \quad \text{for any } a_i \text{ half-integral} \\ \frac{1}{2}(b_1+1)(b_2+1)\cdots(b_r+1) \\ \quad \text{for all } a_i \text{ integral}, B \text{ odd} \\ \frac{1}{2}(b_1+1)(b_2+2)\cdots(b_r+1) - \frac{1}{2} \\ \quad \text{for all } a_i \text{ integral}, B \text{ even.} \end{cases} \tag{13}$$

Solutions to an equation OF THE FORM

$$(A^2+B^2)(C^2+D^2) = E^2 + F^2 \tag{14}$$

are given by the FIBONACCI IDENTITY

$$(a^2+b^2)(c^2+d^2) = (ac \pm bd)^2 + (bc \mp ad)^2 \equiv e^2 + f^2. \tag{15}$$

Another similar identity is the EULER FOUR-SQUARE IDENTITY

$$(a_1^2+a_2^2)(b_1^2+b_2^2)(c_1^2+c_2^2)(d_1^2+d_2^2) = e_1^2+e_2^2+e_3^2+e_4^2 \tag{16}$$

$$\begin{aligned}(a_1^2+a_2^2+a_3^2+a_4^2)(b_1^2+b_2^2+b_3^2+b_4^2) &= (a_1b_1 - a_2b_2 - a_3b_3 - a_4b_4)^2 \\ &+ (a_1b_2 + a_2b_1 + a_3b_4 - a_4b_3)^2 \\ &+ (a_1b_3 - a_2b_4 + a_3b_1 + a_4b_2)^2 \\ &+ (a_1b_4 + a_2b_3 - a_3b_2 + a_4b_1)^2. \end{aligned} \tag{17}$$

Degen's eight-square identity holds for eight squares, but no other number, as proved by Cayley. The two-square identity underlies much of TRIGONOMETRY, the four-square identity some of QUATERNIONS, and the eight-square identity, the CAYLEY ALGEBRA (a non-commutative nonassociative algebra; Bell 1945).

Chen Shuwen found the 2.6.6 equation

$$87^2+233^2+264^2+396^2+496^2+540^2$$
$$=90^2+206^2+309^2+366^2+522^2+523^2. \qquad (18)$$

RAMANUJAN'S SQUARE EQUATION

$$2^n-7=x^2 \qquad (19)$$

has been proved to have only solutions $n=3$, 4, 5, 7, and 15 (Schroeppel 1972).

Diophantine Equation—3rd Powers

As a part of the study of WARING'S PROBLEM, it is known that every positive integer is a sum of no more than 9 positive cubes ($g(3)=9$), that every "sufficiently large" integer is a sum of no more than 7 positive cubes ($G(3)\leq 7$; although it is not known if 7 can be reduced), and that every integer is a sum of at most 5 signed cubes ($eg(3)\leq 5$; although it is not known if 5 can be reduced to 4).

It is known that every n can be written is the form

$$n=A^2+B^2-C^3. \qquad (1)$$

The 3.1.2 equation

$$A^3=B^3+C^3 \qquad (2)$$

is a case of FERMAT'S LAST THEOREM with $n=3$. In fact, this particular case was known not to have any solutions long before the general validity of FERMAT'S LAST THEOREM was established. Thue showed that a Diophantine equation OF THE FORM

$$AX^3-BY^3=1 \qquad (3)$$

for A, B, and l integers, has only finite many solutions (Hardy 1999, pp. 78–9).

Miller and Woollett (1955) and Gardiner *et al.* (1964) investigated integer solutions of

$$A^3+B^3+C^3=D \qquad (4)$$

i.e., numbers representable as the sum of three (positive or negative) CUBIC NUMBERS.

The general rational solution to the 3.1.3 equation

$$A^3=B^3+C^3+D^3 \qquad (5)$$

was found by Euler and Vieta (Dickson 1966, pp. 550–54; Hardy 1999, pp. 20–1). Hardy and Wright (1979, pp. 199–01) give a solution which can be based on the identities

$$a^3(a^3+b^3)^3$$
$$=b^3(a^3+b^3)^3+a^3(a^3-2b^3)^3+b^3(2a^3+b^3)^3 \qquad (6)$$

$$a^3(a^3+2b^3)^3$$
$$=a^3(a^3-b^3)^3+b^3(a^3-b^3)^3+(2a^3+b^3)^3. \qquad (7)$$

This is equivalent to the general 3.2.2 solution found by Ramanujan (Dickson 1966, pp. 500 and 554; Berndt 1994, pp. 54 and 107; Hardy 1999, p. 11, 68, and 237). The smallest integer solutions are

$$3^3+4^3+5^3=6^3 \quad (8)$$

$$1^3+6^3+8^3=9^3 \quad (9)$$

$$7^3+14^3+17^3=20^3 \quad (10)$$

$$11^3+15^3+27^3=29^3 \quad (11)$$

$$28^3+53^3+75^3=84^3 \quad (12)$$

$$26^3+55^3+78^3=87^3 \quad (13)$$

$$33^3+70^3+92^3=105^3 \quad (14)$$

(Fredkin 1972; Madachy 1979, pp. 124 and 141). Other general solutions have been found by Binet (1841) and Schwering (1902), although Ramanujan's formulation is the simplest. No general solution giving *all* POSITIVE integral solutions is known (Dickson 1966, pp. 550–61). Y. Kohmoto has found a $3.1.3^9$ solution,

$$\begin{aligned}2100000^3 &= 2046000^3+882000^3+216000^3\\ &= 1979600^3+1145400^3+85000^3\\ &= 2081100^3+628110^3+1890^3\\ &= 2043150^3+901200^3+30450^3\\ &= 2002280^3+1072480^3+30360^3\\ &= 1960480^3+1199520^3+15200^3\\ &= 1948800^3+1229760^3+30240^3\\ &= 2078160^3+658812^3+13188^3\\ &= 2009112^3+1048040^3+13888^3. \end{aligned} \quad (15)$$

3.1.4 equations include

$$11^3+12^3+13^3+14^3=20^3 \quad (16)$$

$$5^3+7^3+9^3+10^3=13^3. \quad (17)$$

3.1.5 equations include

$$1^3+3^3+4^3+5^3+8^3=9^3 \quad (18)$$

$$3^3+4^3+5^3+8^3+10^3=12^3, \quad (19)$$

and a 3.1.6 equation is given by

$$1^3+5^3+6^3+7^3+8^3+10^3=13^3. \quad (20)$$

The 3.2.2 equation

$$A^3+B^3=C^3+D^3 \quad (21)$$

has a known parametric solution (Dickson 1966, pp. 550–54; Guy 1994, p. 140), and 10 solutions with sum $<10^5$,

$$1729=1^3+12^3+=9^3+10^3 \quad (22)$$

$$4104=2^3+16^3=9^3+15^3 \quad (23)$$

$$13832=2^3+24^3=18^3+20^3 \quad (24)$$

$$20683=10^3+27^3=19^3+24^3 \quad (25)$$

$$32832=4^3+32^3=18^3+30^3 \quad (26)$$

$$39312=2^3+34^3=15^3+33^3 \quad (27)$$

$$40033=9^3+34^3=16^3+33^3 \quad (28)$$

$$46683=3^3+36^3=27^3+30^3 \quad (29)$$

$$64232=17^3+39^3=26^3+36^3 \quad (30)$$

$$65728=12^3+40^3=31^3+33^3 \quad (31)$$

(Sloane's A001235; Moreau 1898). The first number (Madachy 1979, pp. 124 and 141) in this sequence, the so-called HARDY-RAMANUJAN NUMBER, is associated with a story told about Ramanujan by G. H. Hardy, but was known as early as 1657 (Berndt and Bhargava 1993). The smallest number representable in n ways as a sum of cubes is called the nth TAXICAB NUMBER.

Ramanujan gave a general solution to the 3.2.2 equation as

$$(\alpha+\lambda^2\gamma)^3+(\lambda\beta+\gamma)^3=(\lambda\alpha+\gamma)^3+(\beta+\lambda^2\gamma)^3 \quad (32)$$

where

$$\alpha^2+\alpha\beta+\beta^2=3\lambda\gamma^2 \quad (33)$$

(Berndt 1994, p. 107). Another form due to Ramanujan is

$$\begin{aligned}&(A^2+7AB-9B^2)^3+(2A^2-4AB+12B^2)^3\\ &=(2A^2+10B^2)^3+(A^2-9AB-B^2)^3.\end{aligned} \quad (34)$$

Hardy and Wright (1979, Theorem 412) prove that there are numbers that are expressible as the sum of two cubes in n ways for any n (Guy 1994, pp. 140–41). The proof is constructive, providing a method for computing such numbers: given RATIONALS NUMBERS r and s, compute

$$t=\frac{r(r^3+2s^3)}{r^3-s^3} \quad (35)$$

$$u=\frac{s(2r^3+s^3)}{r^3-s^3} \quad (36)$$

$$v=\frac{t(t^3-2u^3)}{t^3+u^3} \quad (37)$$

$$w=\frac{u(2t^3-u^3)}{t^3+u^3}. \quad (38)$$

Then

$$r^3+s^3=t^3-u^3=v^3+w^3 \quad (39)$$

The DENOMINATORS can now be cleared to produce an integer solution. If r/s is picked to be large enough, the v and w will be POSITIVE. If r/s is still larger, the v/w will be large enough for v and w to be used as the

inputs to produce a third pair, etc. However, the resulting integers may be quite large, even for $n=2$. E.g., starting with $3^3+1^3=28$, the algorithm finds

$$28=\left(\frac{28340511}{21446828}\right)^3+\left(\frac{63284705}{21446828}\right)^3, \qquad (40)$$

giving

$$28\cdot 21446828^3=(3\cdot 21446828)^3+21446828^3 \qquad (41)$$

$$=28340511^3+63284705^3. \qquad (42)$$

The numbers representable in three ways as a sum of two cubes (a 3.2^3 equation) are

$$87539319=167^3+436^3=228^3+423^3$$
$$=255^3+414^3 \qquad (43)$$

$$119824488=11^3+493^3=90^3+492^3$$
$$=346^3+428^3 \qquad (44)$$

$$143604279=111^3+522^3=359^3+460^3$$
$$=408^3+423^3 \qquad (45)$$

$$175959000=70^3+560^3=198^3+552^3$$
$$=315^3+525^3 \qquad (46)$$

$$327763000=300^3+670^3=339^3+661^3$$
$$=510^3+580^3 \qquad (47)$$

(Guy 1994, Sloane's A003825). Wilson (1997) found 32 numbers representable in four ways as the sum of two cubes (a 3.2^4 equation). The first is

$$6963472309248=2421^3+19083^3=5436^2+18948^3$$

$$=10200^3+18072^3=13322^3+16630^3. \qquad (48)$$

The smallest known numbers so representable are 6963472309248, 12625136269928, 21131226514944, 26059452841000, ... (Sloane's A003826). Wilson also found six five-way sums,

$$48988659276962496=38787^3+365757^3$$

$$=107839^3+362753^3$$

$$=205292^3+342952^3$$

$$=221424^3+336588^3$$

$$=231518^3+331954^3 \qquad (49)$$

$$490593422681271000=48369^3+788631^3$$

$$=233775^3+781785^3$$

$$=285120^3+776070^3$$

$$=543145^3+691295^3$$

$$=579240^3+666630^3 \qquad (50)$$

$$6355491080314102272=103113^3+1852215^3$$

$$=580488^3+1833120^3$$

$$=788724^3+1803372^3$$

$$=1150792^3+1690544^3$$

$$=1462050^3+1478238^3 \qquad (51)$$

$$27365551142421413376=167751^3+3013305^3$$

$$=265392^3+3012792^3$$

$$=944376^3+2982240^3$$

$$=1283148^3+2933844^3$$

$$=1872184^3+2750288^3 \qquad (52)$$

$$1199962860219870469632=591543^3+10625865^3$$

$$=935856^3+10624056^3$$

$$3330168^3+10516320^3$$

$$=6601912^3+9698384^3$$

$$=8387550^3+8480418^3 \qquad (53)$$

$$111549833098123426841016=1074073^3+48137999^3$$

$$=8787870^3+48040356^3$$

$$=13950972^3+47744382^3$$

$$=24450192^3+45936462^3$$

$$=33784478^3+41791204^3, \qquad (54)$$

and a single six-way sum

$$8230545258248091551205888$$

$$=11239317^3+201891435^3$$

$$=17781264^3+201857064^3$$

$$=63273192^3+199810080^3$$

$$=85970916^3+196567548^3$$

$$=125436328^3+184269296^3$$

$$=159363450^3+161127942^3. \qquad (55)$$

A solution to the 3.4.4 equation is

$$2^3+3^3+10^3+11^3=1^3+5^3+8^3+12^3 \qquad (56)$$

(Madachy 1979, pp. 118 and 133).

3.6.6 equations also exist:

$$1^3+2^3+4^3+8^3+9^3+12^3$$
$$=3^3+5^3+6^3+7^3+10^3+11^3 \qquad (57)$$

$$87^3 + 233^3 + 264^3 + 396^3 + 496^3 + 540^3$$
$$= 90^3 + 206^3 + 309^3 + 366^3 + 522^3 + 523^3. \quad (58)$$

(Madachy 1979, p. 142; Chen Shuwen).

Euler gave the general solution to

$$A^3 + B^3 = C^2 \quad (59)$$

as

$$A = 3n^2 + 6n^2 - n \quad (60)$$

$$B = -3n^3 + 6n^2 + n \quad (61)$$

$$C = 6n^2(3n^2 + 1). \quad (62)$$

Diophantine Equation—4th Powers

As a consequence of Matiyasevich's refutation of Hilbert's 10th problem, it can be proved that there does not exists a general algorithm for solving a general quartic Diophantine equation. However, the algorithm for constructing such an unsolvable quartic Diophantine equation can require arbitrarily many variables (Matiyasevich 1993).

As a part of the study of WARING'S PROBLEM, it is known that every positive integer is a sum of no more than 19 positive biquadrates ($g(4) = 19$), that every "sufficiently large" integer is a sum of no more than 16 positive biquadrates ($G(4) = 16$), and that every integer is a sum of at most 10 signed biquadrates ($eg(4) \leq 10$; although it is not known if 10 can be reduced to 9). The first few numbers n which are a sum of four fourth POWERS ($m - 1$ equations) are 353, 651, 2487, 2501, 2829, ... (Sloane's A003294).

The 4.1.2 equation

$$x^4 = y^4 + z^4 \quad (1)$$

is a case of FERMAT'S LAST THEOREM with $n = 4$ and therefore has no solutions. In fact, the equations

$$x^4 \pm y^4 - z^2 \quad (2)$$

also have no solutions in INTEGERS (Nagell 1951, pp. 227 and 229). The equation

$$x^4 - y^4 = 2z^2 \quad (3)$$

has no solutions in integers (Nagell 1951, p. 230). The only number OF THE FORM

$$4x^4 + y^4 \quad (4)$$

which is PRIME is 5 (Baudran 1885, Le Lionnais 1983).

Let the notation $p.m.n$ stand for the equation consisting of a sum of m pth powers being equal to a sum of n pth powers. In 1772, Euler proposed that the 4.1.3 equation

$$A^4 + B^4 + C^4 = D^4 \quad (5)$$

had no solutions in INTEGERS (Lander *et al.* 1967). This assertion is known as the EULER QUARTIC

CONJECTURE. Ward (1948) showed there were no solutions for $D \leq 10,000$, which was subsequently improved to $D \leq 220,000$ by Lander *et al.* (1967). However, the EULER QUARTIC CONJECTURE was disproved in 1987 by N. Elkies, who, using a geometric construction, found

$$2,682,440^4 + 15,365,639^4 + 18,796,760^4 = 20,615,673^4 \tag{6}$$

and showed that infinitely many solutions existed (Guy 1994, p. 140). In 1988, Roger Frye found

$$95,800^4 + 217,519^4 + 414,560^4 = 422,481^4 \tag{7}$$

and proved that there are no solutions in smaller INTEGERS (Guy 1994, p. 140). Another solution was found by Allan MacLeod in 1997,

$$638,523,249^4 = 630,662,624^4 + 275,156,240^4 + 219,076,465^4 \tag{8}$$

(Ekl 1998). It is not known if there is a parametric solution. In contrast, there are many solutions to the equation

$$A^4 + B^4 + C^4 = 2D^4 \tag{9}$$

(see below).

The 4.1.4 equation

$$A^4 + B^4 + C^4 + D^4 = E^4 \tag{10}$$

has solutions

$$30^4 + 120^4 + 272^4 + 315^4 = 353^4 \tag{11}$$

$$240^4 + 340^4 + 430^4 + 599^4 = 651^4 \tag{12}$$

$$435^4 + 710^4 + 1384^5 + 2420^4 = 2487^4 \tag{13}$$

$$1130^4 + 1190^4 + 1432^4 + 2365^4 = 2501^4 \tag{14}$$

$$850^4 + 1010^4 + 1546^4 + 2745^4 = 2829^4 \tag{15}$$

$$2270^4 + 2345^4 + 2460^4 + 3152^4 = 3723^4 \tag{16}$$

$$350^4 + 1652^4 + 3230^4 + 3395^4 = 3973^4 \tag{17}$$

$$205^4 + 1060^4 + 2650^4 + 4094^4 = 4267^4 \tag{18}$$

$$1394^4 + 1750^4 + 3545^4 + 3670^4 = 4333^4 \tag{19}$$

$$699^4 + 700^4 + 2840^4 + 4250^4 = 4449^4 \tag{20}$$

$$380^4 + 1660^4 + 1880^4 + 4907^4 = 4949^4 \tag{21}$$

$$1000^4 + 1120^4 + 3233^4 + 5080^4 = 5281^4 \tag{22}$$

$$410^4 + 1412^4 + 3910^4 + 5055^4 = 5463^4 \tag{23}$$

$$955^4 + 1770^4 + 2634^4 + 5400^4 = 5491^4 \tag{24}$$

$$30^4 + 1680^4 + 3043^4 + 5400^4 = 5543^4 \tag{25}$$

$$1354^4 + 1810^4 + 4355^4 + 5150^4 = 5729^4 \tag{26}$$

$$542^4 + 2770^4 + 4280^4 + 5695^4 = 6167^4 \tag{27}$$

$$50^4 + 885^4 + 5000^4 + 5984^4 = 6609^4 \tag{28}$$

$$1490^4 + 3468^4 + 4790^4 + 6185^4 = 6801^4 \tag{29}$$

$$1390^4 + 2850^4 + 5365^4 + 6368^4 = 7101^4 \tag{30}$$

$$160^4 + 1345^4 + 2790^4 + 7166^4 = 7209^4 \tag{31}$$

$$800^4 + 3052^4 + 5440^4 + 6635^4 = 7339^4 \tag{32}$$

$$2230^4 + 3196^4 + 5620^4 + 6995^4 = 7703^4 \tag{33}$$

(Norrie 1911, Patterson 1942, Leech 1958, Brudno 1964, Lander *et al.* 1967), but it is not known if there is a parametric solution (Guy 1994, p. 139).

There are an infinite number of solutions to the 4.1.5 equation

$$A^4 = B^4 + C^4 + D^4 + E^4 + F^4. \tag{34}$$

Some of the smallest are

$$2^4 + 2^4 + 3^4 + 4^4 + 4^4 = 5^4 \tag{35}$$

$$4^4 + 6^4 + 8^4 + 9^4 + 14^4 = 15^4 \tag{36}$$

$$4^4 + 21^4 + 22^4 + 26^4 + 28^4 = 35^4 \tag{37}$$

$$1^4 + 2^4 + 12^4 + 24^4 + 44^4 = 45^4 \tag{38}$$

$$1^4 + 8^4 + 12^4 + 32^4 + 64^4 = 65^4 \tag{39}$$

$$2^4 + 39^4 + 44^4 + 46^4 + 52^4 = 65^4 \tag{40}$$

$$22^4 + 52^4 + 57^4 + 74^4 + 76^4 = 95^4 \tag{41}$$

$$22^4 + 28^4 + 63^4 + 72^4 + 94^4 = 105^4 \tag{42}$$

(Berndt 1994). Berndt and Bhargava (1993) and Berndt (1994, pp. 94–6) give Ramanujan's solutions for arbitrary s, t, m, and n,

$$(8s^2 + 40st - 24t^2)^4 + (6s^2 - 44st - 18t^2)^4 + (14s^2 - 4st - 42t^2)^4 + (9s^2 + 27t^2)^4 + (4s^2 + 12t^2)^4 = (15s^2 + 45t^2)^4, \tag{43}$$

and

$$(4m^2 - 12n^2)^4 + (3m^2 + 9n^2)^4 + (2m^2 - 12mn - 6n^2)^4 + (4m^2 + 12n^2)^4 + (2m^2 + 12mn - 6n^2)^4 = (5m^2 + 15n^2)^4. \tag{44}$$

These are also given by Dickson (1966, p. 649), and two general FORMULAS are given by Beiler (1966, p. 290). Other solutions are given by Fauquembergue (1898), Haldeman (1904), and Martin (1910).

Parametric solutions to the 4.2.2 equation

$$A^4+B^4=C^4+D^4 \quad (45)$$

are known (Euler 1802; Gérardin 1917; Guy 1994, pp. 140–41), but no "general" solution is known (Hardy 1999, p. 21). A few specific solutions are

$$59^4+158^4=133^4+134^4=635,318,657 \quad (46)$$

$$7^4+239^4=157^4+227^4=3,262,811,042 \quad (47)$$

$$193^4+292^4=256^4+257^4=8,657,437,697 \quad (48)$$

$$298^4+497^4=271^4+502^4=68,899,596,497 \quad (49)$$

$$514^4+359^4=103^4+542^4=86,409,838,577 \quad (50)$$

$$222^4+631^4=503^4+558^4=160,961,094,577 \quad (51)$$

$$21^4+717^4=471^4+681^4=264,287,694,402 \quad (52)$$

$$76^4+1203^4=653^4+1176^4 = 2,094,447,251,857 \quad (53)$$

$$997^4+1342^4=878^4+1381^4 = 4,231,525,221,377 \quad (54)$$

(Sloane's A003824 and A018786; Richmond 1920; Dickson, pp. 60–2; Dickson 1966, pp. 644–47; Leech 1957; Berndt 1994, p. 107; Ekl 1998 [with typo]), the smallest of which is due to Euler (Hardy 1999, p. 21). Lander *et al.* (1967) give a list of 25 primitive 4.2.2 solutions. General (but incomplete) solutions are given by

$$x=a+b \quad (55)$$

$$y=c-d \quad (56)$$

$$u=a-b \quad (57)$$

$$v=c+d, \quad (58)$$

where

$$a=n(m^2+n^2)(-m^4+18m^2n^2-n^4) \quad (59)$$

$$b=2m(m^6+10m^4n^4+m^2n^4+4n^6) \quad (60)$$

$$c=2n(4m^6+m^4n^2+10m^2n^4+n^6) \quad (61)$$

$$d=m(m^2+n^2)(-m^4+18m^2n^2-n^4) \quad (62)$$

(Hardy and Wright 1979).

Parametric solutions to the 4.2.3 equation

$$A^4+B^4=C^4+D^4+E^4 \quad (63)$$

are known (Gérardin 1910, Ferrari 1913). The smallest solution is

$$3^4+5^4+8^4=7^4+7^4 \quad (64)$$

(Lander *et al.* 1967).

Ramanujan gave the 4.2.4 equation

$$3^4+9^4=5^4+5^4+6^4+8^4. \quad (65)$$

Ramanujan gave the 4.3.3 equations

$$2^4+4^4+7^4=3^4+6^4+6^4 \quad (66)$$

$$3^4+7^4+8^4=1^4+2^4+9^4 \quad (67)$$

$$6^4+9^4+12^4=2^4+2^4+13^4 \quad (68)$$

(Berndt 1994, p. 101). Similar examples can be found in Martin (1896). Parametric solutions were given by Gérardin (1911).

Ramanujan also gave the general expression

$$3^4+(2x^4-1)^4+(4x^5+x)^4 = (4x^4+1)^4+(6x^4-3)^4+(4x^5-5x)^4 \quad (69)$$

(Berndt 1994, p. 106). Dickson (1966, pp. 653–55) cites several FORMULAS giving solutions to the 4.3.3 equation, and Haldeman (1904) gives a general FORMULA.

Ramanujan gave the 4.3.4 identities

$$2^4+2^4+7^4=4^4+4^4+5^4+6^4 \quad (70)$$

$$3^4+9^4+14^4=7^4+8^4+10^4+13^4 \quad (71)$$

$$7^4+10^4+13^4=5^4+5^4+6^4+14^4 \quad (72)$$

(Berndt 1994, p. 101). Haldeman (1904) gives general FORMULAS for 4– and 4– equations.

Ramanujan gave

$$2(ab+ac+bc)^2=a^4+b^4+c^4 \quad (73)$$

$$2(ab+ac+bc)^4=a^4(b-c)^4+b^4(c-a)^4+c^4(a-b)^4 \quad (74)$$

$$2(ab+ac+bc+)^6 = (a^2b+b^2c+c^2a)^4+(ab^2+bc^2+ca^2)^4+3(abc)^4 \quad (75)$$

$$2(ab+ac+bc)^8=(a^3+2abc)^4(b-c)^4 + (b^3+2abc)^4(c-a)^4+(c^3+2abc)^4(a-b)^4, \quad (76)$$

where

$$a+b+c=0 \quad (77)$$

(Berndt 1994, pp. 96–7). FORMULA (74) is equivalent to FERRARI'S IDENTITY

$$(a^2+2ac-2bc-b^2)^4+(b^2-2ab-2ac-c^2)^4 +(c^2+2ab+2bc-a^2)^4 = 2(a^2+b^2+c^2-ab+ac+bc)^4. \quad (78)$$

BHARGAVA'S THEOREM is a general identity which gives the above equations as a special case, and may

have been the route by which Ramanujan proceeded. Another identity due to Ramanujan is

$$(a+b+c)^4+(b+c+d)^4+(a-d)^4$$
$$=(c+d+a)^4+(d+a+b)^4+(b-c)^4, \quad (79)$$

where $a/b=c/d$, and 4 may also be replaced by 2 (Ramanujan 1957, Hirschhorn 1998).

V. Kyrtatas noticed that $a=3$, $b=7$, $c=20$, $d=25$, $e=38$, and $f=39$ satisfy

$$\frac{a^4+b^4+c^4}{d^4+e^4+f^4}=\frac{a+b+c}{d+e+f} \quad (80)$$

and asks if there are any other distinct integer solutions.

Diophantine Equation—5th Powers

The 5.1.2 fifth-order Diophantine equation

$$A^5=B^5+C^5 \quad (1)$$

is a special case of Fermat's last theorem with $n=5$, and so has no solution. improving on the results on Lander *et al.* (1967), who checked up to 2.8×10^{14}. (In fact, no solutions are known for powers of 6 or 7 either.) No solutions to the 5.1.3 equation

$$A^5+B^5+C^5=D^5 \quad (2)$$

are known (Lander *et al.* 1967). For 4 fifth powers, we have the 5.1.4 equation

$$27^5+84^5+110^5+133^5=144^5 \quad (3)$$

(Lander and Parkin 1967, Lander *et al.* 1967, Ekl 1998), but it is not known if there is a parametric solution (Guy 1994, p. 140). Sastry (1934) found a 2-parameter solution for 5.1.5 equations

$$(75v^5-u^5)^5+(u^5+25v^5)^5+(u^5-25v^5)^5$$
$$+(10u^3v^2)^5+(50uv^4)^5=(u^5+75v^5)^5 \quad (4)$$

(quoted in Lander and Parkin 1967), and Lander and Parkin (1967) found the smallest numerical solutions. Lander *et al.* (1967) give a list of the smallest solutions, the first few being

$$19^5+43^5+46^5+47^5+67^5=72^5 \quad (5)$$

$$21^5+23^5+37^5+79^5+84^5=94^5 \quad (6)$$

$$7^5+43^5+57^5+80^5+100^5=107^5 \quad (7)$$

$$78^5+120^5+191^5+259^5+347^5=365^5 \quad (8)$$

$$79^5+202^5+258^5+261^5+395^5=415^5 \quad (9)$$

$$4^5+26^5+139^5+296^5+412^5=427^5 \quad (10)$$

$$31^5+105^5+139^5+314^5+416^5=435^5 \quad (11)$$

$$54^5+91^5+101^5+404^5+430^5=480^5 \quad (12)$$

$$19^5+201^5+347^5+388+448^5=503^5 \quad (13)$$

$$159^5+172^5+200^5+356^5+513^5=530^5 \quad (14)$$

$$218^5+276^5+385^5+409^5+495^5=553^5 \quad (15)$$

$$2^5+298^5+351^5+474^5+500^5=575^5 \quad (16)$$

(Lander and Parkin 1967, Lander *et al.* 1967). The 5.1.6 equation has solutions

$$4^5+5^5+6^5+7^5+9^5+11^5=12^5 \quad (17)$$

$$5^5+10^5+11^5+16^5+19^5+29^5=30^5 \quad (18)$$

$$15^5+16^5+17^5+22^5+24^5+28^5=32^5 \quad (19)$$

$$13^5+18^5+23^5+31^5+36^5+66^5=67^5 \quad (20)$$

$$7^5+20^5+29^5+31^5+34^5+66^5=67^5 \quad (21)$$

$$22^5+35^5+48^5+58^5+61^5+64^5=78^5 \quad (22)$$

$$4^5+13^5+19^5+20^5+67^5+96^5=99^5 \quad (23)$$

$$6^5+17^5+60^5+64^5+73^5+89^5=99^5 \quad (24)$$

(Martin 1887, 1888, Lander and Parkin 1967, Lander *et al.* 1967). The smallest 5.1.7 solution is

$$1^5+7^5+8^5+14^5+15^5+18^5+20^5=23^5 \quad (25)$$

(Lander *et al.* 1967).

No solutions to the 5.2.2 equation

$$A^5+B^5=C^5+D^5 \quad (26)$$

are known, despite the fact that sums up to 1.026×10^{26} have been checked (Guy 1994, p. 140). The smallest 5.2.3 solution is

$$14132^5+220^5=14068^5+6237^5+5027^5 \quad (27)$$

(B. Scher and E. Seidl 1996, Ekl 1998). Sastry's (1934) 5.1.5 solution gives some 5.2.4 solutions. The smallest primitive 5.2.4 solutions are

$$4^5+10^5+20^5+28^5=3^5+29^5 \quad (28)$$

$$5^5+13^5+25^5+37^5=12^5+38^5 \quad (29)$$

$$26^5+29^5+35^5+50^5=28^5+52^5 \quad (30)$$

$$5^5+25^5+62^5+63^5=61^5+64^5 \quad (31)$$

$$6^5+50^5+53^5+82^5=16^5+85^5 \quad (32)$$

$$56^5+63^5+72^5+86^5=31^5+96^5 \quad (33)$$

$$44^5+58^5+67^5+94^5=14^5+99^5 \quad (34)$$

$$11^5+13^5+37^5+99^5=63^5+97^5 \quad (35)$$

$$48^5+57^5+76^5+100^5=25^5+106^5 \quad (36)$$

$$58^5+76^5+79^5+102^5=54^5+111^5 \quad (37)$$

(Rao 1934, Moessner 1948, Lander *et al.* 1967). The smallest primitive 5.2.5 solutions are

$$4^5+5^5+7^5+16^5+21^5=1^5+22^5 \quad (38)$$

$$9^5+11^5+14^5+18^5+30^5=23^5+29^5 \quad (39)$$

$$10^5+14^5+26^5+31^5+33^5=16^5+38^5 \quad (40)$$

$$4^5+22^5+29^5+35^5+36^5=24^5+42^5 \quad (41)$$

$$8^5+15^5+17^5+19^5+45^5=30^5+44^5 \quad (42)$$

$$5^5+6^5+26^5+27^5+44^5=36^5+42^5 \quad (43)$$

(Rao 1934, Lander *et al.* 1967).

Parametric solutions are known for the 5.3.3 (Sastry and Lander 1934; Moessner 1951; Swinnerton-Dyer 1952; Lander 1968; Bremmer 1981; Guy 1994, pp. 140 and 142; Choudhry 1999). Swinnerton-Dyer (1952) gave two parametric solutions to the 5.3.3 equation but, forty years later, W. Gosper discovered that the second scheme has an unfixable bug. Choudhry (1999) gave a parametric solution to the more general equation

$$ax^5+by^5+cx^5=au^5+bv^5+cw^5 \quad (44)$$

with $a+b+c=0$. The smallest primitive solutions to the 5.3.3 equation with unit coefficients are

$$24^5+28^5+67^5=3^5+54^5+62^5 \quad (45)$$

$$18^5+44^5+66^5=13^5+51^5+64^5 \quad (46)$$

$$21^5+43^5+74^5=8^5+62^5+68^5 \quad (47)$$

$$56^5+67^5+83^5=53^5+72^5+81^5 \quad (48)$$

$$49^5+75^5+107^5=39^5+92^5+100^5 \quad (49)$$

(Moessner 1939, Moessner 1948, Lander *et al.* 1967, Ekl 1998).

A two-parameter solution to the 5.3.4 equation was given by Xeroudakes and Moessner (1958). Gloden (1949) also gave a parametric solution. The smallest solution is

$$1^5+8^5+14^5+27^5=3^5+22^5+25^5 \quad (50)$$

(Rao 1934, Lander *et al.* 1967).

Several parametric solutions to the 5.4.4 equation were found by Xeroudakes and Moessner (1958). The smallest 5.4.4 solution is

$$5^5+6^5+6^5+8^5=4^5+7^5+7^5+7^5 \quad (51)$$

(Rao 1934, Lander *et al.* 1967). The first 5.4.4.4 equation is

$$3^5+48^5+52^5+61^5=13^5+36^5+51^5+64^5 = 18^5+36^5+44^5+66^5 \quad (52)$$

(Lander *et al.* 1967).

Moessner and Gloden (1944) give the 5.5.6 solution

$$22^5+17^5+16^5+6^5+5^5 = 21^5+20^5+12^5+10^5+2^5+1^5. \quad (53)$$

Chen Shuwen found the 5.6.6 solution

$$87^5+233^5+264^5+396^5+496^5+540^5 = 90^5+206^5+309^5+366^5+522^5+523^5. \quad (54)$$

Diophantine Equation—6th Powers

The 6.1.2 equation

$$A^6=B^6+C^6 \quad (1)$$

is a special case of FERMAT'S LAST THEOREM with $n=6$, and so has no solution. No 6.1.n solutions are known for $n \leq 6$ (Lander *et al.* 1967; Guy 1994, p. 140). The smallest 6.1.7 solution is

$$74^6+234^6+402^6+474^6+702^6+894^6+1017^6 = 1141^6 \quad (2)$$

(Lander *et al.* 1967; Ekl 1998). The smallest primitive 6.1.8 solutions are

$$8^6+12^6+30^6+78^6+102^6+138^6+165^6+246^6 = 251^6 \quad (3)$$

$$48^6+111^6+156^6+186^6+188^6+228^6+240^6+426^6 = 431^6 \quad (4)$$

$$93^6+93^6+195^6+197^6+303^6+303^6+303^6+411^6 = 440^6 \quad (5)$$

$$219^6+255^6+261^6+267^6+289^6+351^6+351^6+351^6 = 440^6 \quad (6)$$

$$12^6+66^6+138^6+174^6+212^6+288^6+306^6+441^6 = 455^6 \quad (7)$$

$$12^6+48^6+222^6+236^6+333^6+384^6+390^6+426^6 = 493^6 \quad (8)$$

$$66^6+78^6+144^6+228^6+256^6+288^6+435^6+444^6 = 499^6 \quad (9)$$

$$16^6+24^6+60^6+156^6+204^6+276^6+330^6+492^6 = 502^6 \quad (10)$$

$$61^6+96^6+156^6+228^6+276^6+318^6+354^6+534^6 = 547^6 \quad (11)$$

$$170^6+177^6+276^6+312^6+312^6+408^6+450^6+498^6 = 559^6 \quad (12)$$

$$60^6+102^6+126^6+261^6+270^6+338^6+354^6+570^6 = 581^6 \quad (13)$$

$$57^6+146^6+150^6+360^6+390^6+402^6+444^6+528^6 = 583^6 \quad (14)$$

$$33^6+72^6+122^6+192^6+204^6+390^6+534^6+534^6 = 607^6 \quad (15)$$

$$12^6+90^6+114^6+114^6+273^6+306^6+492^6+592^6 = 623^6 \quad (16)$$

(Lander *et al.* 1967). The smallest 6.1.9 solution is

$$1^6+17^6+19^6+22^6+31^6+37^6+37^6+41^6+49^6 = 54^6 \quad (17)$$

(Lander *et al.* 1967). The smallest 6.1.10 solution is

$$2^6+4^6+7^6+14^6+16^6+26^6+26^6+30^6+32^6+32^6 = 39^6 \quad (18)$$

(Lander *et al.* 1967). The smallest 6.1.11 solution is

$$2^6+5^6+5^6+5^6+7^6+7^6+9^6+9^6+10^6+14^6+17^6 = 18^6 \quad (19)$$

(Lander *et al.* 1967). There is also at least one 6.1.16 identity,

$$1^6+2^6+4^6+5^6+6^6+7^6+9^6+12^6+13^6+15^6 +16^6+18^6+20^6+21^6+22^6+23^6 = 28^6 \quad (20)$$

(Martin 1893). Moessner (1959) gave solutions for 6.1.16, 6.1.18, 6.1.20, and 6.1.23 equations.

Ekl (1996) has searched and found no solutions to the 6.2.2

$$A^6+B^6 = C^6+D^6 \quad (21)$$

with sums less than 7.25×10^{26}. No solutions are known to the 6.2.3 or 6.2.4 equations. The smallest primitive 6.2.5 equations are

$$1092^6+861^6+602^6+212^6+84^6 = 1117^6+770^6 \quad (22)$$

$$1893^6+1468^6+1407^6+1302^6+1246^6 = 2041^6+691^6 \quad (23)$$

$$2184^6+2096^6+1484^6+1266^6+1239^6 = 2441^6+752^6 \quad (24)$$

$$2653^6+2962^6+1488^6+1281^6+390^6 = 2827^6+151^6 \quad (25)$$

$$2954^6+2481^6+850^6+798^6+420^6 = 2959^6+2470^6 \quad (26)$$

(E. Brisse 1999 Resta 1999, PowerSum). The smallest 6.2.6 equation is

$$241^6+17^6 = 218^6+210^6+118^6+2.63^6+42^6 \quad (27)$$

(Ekl 1998). The smallest 6.2.7 solution is

$$18^6+22^6+36^6+58^6+69^6+78^6+78^6 = 56^6+91^6 \quad (28)$$

(Lander *et al.* 1967). The smallest 6.2.8 solution is

$$8^6+10^6+12^6+15^6+24^6+30^6+33^6+36^6 = 35^6+37^6 \quad (29)$$

(Lander *et al.* 1967). The smallest 6.2.9 solution is

$$1^6+5^6+5^6+7^6+13^6+13^6+13^6+17^6+19^6 = 6^6+21^6 \quad (30)$$

(Lander *et al.* 1967). The smallest 6.2.10 solution is

$$1^6+1^6+1^6+4^6+4^6+7^6+9^6+11^6+11^6+11^6 = 12^6+12^6 \quad (31)$$

(Lander *et al.* 1967).

Parametric solutions are known for the 6.3.3 equation

$$A^6+B^6+C^6 = D^6+E^6+F^6 \quad (32)$$

(Guy 1994, pp. 140 and 142). Known solutions are

$$3^6+19^6+22^6 = 10^6+15^6+23^6 \quad (33)$$

$$36^6+37^6+67^6 = 15^6+52^6+65^6 \quad (34)$$

$$33^6+47^6+74^6 = 23^6+54^6+73^6 \quad (35)$$

$$32^6+43^6+81^6 = 3^6+55^6+80^6 \quad (36)$$

$$37^6+50^6+81^6 = 11^6+65^6+78^6 \quad (37)$$

$$25^6+62^6+138^6 = 82^6+92^6+135^6 \quad (38)$$

$$51^6+113^6+136^6 = 40^6+125^6+129^6 \quad (39)$$

$$71^6+92^6+147^6 = 1^6+132^6+133^6 \quad (40)$$

$$111^6+121^6+230^6 = 26^6+169^6+225^6 \quad (41)$$

$$75^6+142^6+245^6 = 14^6+163^6+243^6 \quad (42)$$

(Rao 1934, Lander *et al.* 1967, Ekl 1998). Ekl (1998) mentions but does not list the 87 smallest solutions to the 6.2.6 equation. The smallest primitive 6.3.4 solutions are

$$73^6+58^6+41^6 = 70^6+65^6+32^6+15^6 \quad (43)$$

$$85^6+62^6+61^6 = 83^6+69^6+56^6+52^6 \quad (44)$$

$$85^6+74^6+61^6 = 87^6+71^6+56^6+26^6 \quad (45)$$

$$90^6+88^6+11^6 = 92^6+78^6+74^6+21^6 \quad (46)$$

$$95^6+83^6+26^6 = 101^6+28^6+24^6+23^6 \quad (47)$$

$$130^6+44^6+23^6 = 119^6+108^6+86^6+38^6 \quad (48)$$

$$125^6+114^6+38^6 = 126^6+104^6+93^6+68^6 \quad (49)$$

$$205^6 + 113^6 + 18^6 = 198^6 + 148^6 + 133^6 + 39^6 \quad (50)$$

$$211^6 + 123^6 + 34^6 = 210^6 + 134^6 + 73^6 + 39^6 \quad (51)$$

$$212^6 + 164^6 + 103^6 = 217^6 + 130^6 + 114^6 + 8^6 \quad (52)$$

$$222^6 + 34^6 + 25^6 = 217^6 + 156^6 + 96^6 + 68^6 \quad (53)$$

$$218^6 + 167^6 + 29^6 = 224^6 + 107^6 + 102^6 + 65^6 \quad (54)$$

$$226^6 + 110^6 + 17^6 = 224^6 + 143^6 + 72^6 + 34^6 \quad (55)$$

$$244^6 + 123^6 + 112^6 = 238^6 + 180^6 + 91^6 + 72^6 \quad (56)$$

$$241^6 + 172^6 + 156^6 = 246^6 + 145^6 + 132^6 + 56^6 \quad (57)$$

$$257^6 + 155^6 + 6^6 = 252^6 + 181^6 + 143^6 + 114^6 \quad (58)$$

$$265^6 + 147^6 + 12^6 = 231^6 + 221^6 + 210^6 + 114^6 \quad (59)$$

$$260^6 + 218^6 + 185^6 = 276^6 + 152^6 + 112^6 + 25^6 \quad (60)$$

$$305^6 + 85^6 + 66^6 = 273^6 + 267^6 + 172^6 + 122^6 \quad (61)$$

$$312^6 + 241^6 + 33^6 = 315^6 + 228^6 + 99^6 + 2^6 \quad (62)$$

$$331^6 + 234^6 + 59^6 = 306^6 + 294^6 + 151^6 + 95^6 \quad (63)$$

$$332^6 + 243^6 + 43^6 = 338^6 + 177^6 + 168^6 + 95^6 \quad (64)$$

$$351^6 + 265^6 + 221^6 = 336^6 + 309^6 + 169^6 + 73^6 \quad (65)$$

$$365^6 + 137^6 + 126^6 = 360^6 + 234^6 + 175^6 + 133^6 \quad (66)$$

$$360^6 + 265^6 + 200^6 = 336^6 + 318^6 + 212^6 + 169^6 \quad (67)$$

$$348^6 + 325^6 + 36^6 = 357^6 + 276^6 + 276^6 + 82^6 \quad (68)$$

$$373^6 + 288^6 + 104^6 = 363^6 + 292^6 + 266^6 + 120^6 \quad (69)$$

$$386^6 + 113^6 + 62^6 = 378^6 + 260^6 + 209^6 + 88^6 \quad (70)$$

(Lander *et al.* 1967, Ekl 1998).

Moessner (1947) gave three parametric solutions to the 6.4.4 equation. The smallest 6.4.4 solution is

$$2^6 + 2^6 + 9^6 + 9^6 = 3^6 + 5^6 + 6^6 + 10^6 \quad (71)$$

(Rao 1934, Lander *et al.* 1967). The smallest 6.4.4.4 solution is

$$1^6 + 34^6 + 49^6 + 111^6 = 7^6 + 43^6 + 69^6 + 110^6 = 18^6 + 25^6 + 77^6 + 109^6 \quad (72)$$

(Lander *et al.* 1967).

Moessner and Gloden (1944) give the 6.7.8 solution

$$32^6 + 31^6 + 23^6 + 22^6 + 13^6 + 6^6 + 5^6 = 33^6 + 28^6 + 27^6 + 20^6 + 11^6 + 10^6 + 2^6 + 1^6. \quad (73)$$

Diophantine Equation—7th Powers

The 7.1.2 equation

$$A^7 + B^7 = C^7 \quad (1)$$

is a special case of FERMAT'S LAST THEOREM with $n = 7$, and so has no solution. No solutions to the 7.1.3, 7.1.4, 7.1.5, 7.1.6 equations are known. There is now a known solutions to the 7.1.7 equation,

$$568^7 = 525^7 + 439^7 + 430^7 + 413^7 + 266^7 + 258^7 + 127^7 \quad (2)$$

(M. Dodrill 1999, PowerSum), requiring an update by Guy (1994, p. 140). The smallest 7.1.8 solution is

$$12^7 + 35^7 + 53^7 + 58^7 + 64^7 + 83^7 + 85^7 + 90^7 = 102^7 \quad (3)$$

(Lander *et al.* 1967, Ekl 1998). The smallest 7.1.9 solution is

$$6^7 + 14^7 + 20^7 + 22^7 + 27^7 + 33^7 + 41^7 + 50^7 + 59^7 = 62^7 \quad (4)$$

(Lander *et al.* 1967).

No solutions to the 7.2.2, 7.2.3, 7.2.4, or 7.2.5 equations are known. The smallest 7.2.6 equation is

$$125^7 + 24^7 = 121^7 + 94^7 + 83^7 + 61^7 + 57^7 + 27^7 \quad (5)$$

(Meyrignac). The smallest 7.2.8 solution is

$$5^7 + 6^7 + 7^7 + 15^7 + 15^7 + 20^7 + 28^7 + 31^7 = 10^7 + 33^7 \quad (6)$$

(Lander *et al.* 1967, Ekl 1998). A 7.2.10.10 solution is

$$2^7+27^7=4^7+8^7+13^7+14^7+14^7+16^7+18^7+22^7+23^7+23^7=7^7+7^7+9^7+13^7+14^7+18^7+20^7+22^7+22^7+23^7 \quad (7)$$

(Lander *et al.* 1967).

No solutions to the 7.3.3 equation are known (Ekl 1996), nor are any to 7.3.4. The smallest 7.3.5 equations are

$$96^7+41^7+17^7=87^7+2\cdot 77^7+68^7+56^7 \quad (8)$$

$$153^7+43^7+14^7=140^7+137^7+59^7+42^7+42^7. \quad (9)$$

No solutions are known to the 7.3.6 equation. The smallest 7.3.7 solution is

$$7^7+7^7+12^7+16^7+27^7+28^7+31^7=26^7+30^7+30^7 \quad (10)$$

(Lander *et al.* 1967).

Guy (1994, p. 140) asked if a 7.4.4 equation exists. The following solution provide an affirmative answer

$$149^7+123^7+14^7+10^7=146^7+129^7+90^7+15^7 \quad (11)$$

$$194^7+150^7+105^7+23^7=192^7+152^7+132^7+38^7 \quad (12)$$

$$354^7+112^7+52^7+19^7=343^7+281^7+46^7+35^7 \quad (13)$$

(Ekl 1996, Elk 1998, M. Lau 1999, PowerSum). Numerical solutions to the 7.4.5 equation are given by Gloden (1948). The smallest primitive 7.4.5 solutions are

$$50^7+43^7+16^7+12^7=52^7+29^7+26^7+11^7+3^7 \quad (14)$$

$$81^7+58^7+19^7+9^7=77^7+68^7+56^7+48^7+2^7 \quad (15)$$

$$87^7+74^7+69^7+40^7=82^7+79^7+75^7+25^7+9^7 \quad (16)$$

$$99^7+76^7+32^7+29^7=93^7+88^7+66^7+36^7+35^7 \quad (17)$$

$$98^7+82^7+58^7+34^7=99^7+75^7+69^7+16^7+13^7 \quad (18)$$

$$104^7+96^7+60^7+14^7=102^7+95^7+81^7+57^7+23^7 \quad (19)$$

$$111^7+102^7+40^7+29^7=112^7+96^7+82^7+55^7+21^7 \quad (20)$$

$$113^7+102^7+86^7+23^7=120^7+81^7+58^7+55^7+10^7 \quad (21)$$

(Lander *et al.* 1967, Ekl 1998).

Gloden (1949) gives parametric solutions to the 7.5.5 equation. The first few 7.5.5 solutions are

$$8^7+8^7+13^7+16^7+19^7=2^7+12^7+15^7+17^7+18^7 \quad (22)$$

$$4^7+8^7+14^7+16^7+23^7=7^7+7^7+9^7+20^7+22^7 \quad (23)$$

$$11^7+12^7+18^7+21^7+26^7=9^7+10^7+22^7+23^7+24^7 \quad (24)$$

$$6^7+12^7+20^7+22^7+27^7=10^7+13^7+13^7+25^7+26^7 \quad (25)$$

$$3^7+13^7+17^7+24^7+38^7=14^7+26^7+32^7+32^7+33^7 \quad (26)$$

(Lander *et al.* 1967). Ekl (1998) mentions but does not list 107 primitive solutions to 7.5.5.

A parametric solution to the 7.6.6 equation was given by Sastry and Rai (1948). The smallest is

$$2^7+3^7+6^7+6^7+10^7+13^7=1^7+1^7+7^7+7^7+12^7+12^7 \quad (27)$$

(Lander *et al.* 1967). Another found by Chen Shuwen is

$$87^7+233^7+264^7+396^7+496^7+540^7=90^7+206^7+309^7+366^7+522^7+523^7. \quad (28)$$

Moessner and Gloden (1944) gave the 7.9.10 solution

$$42^7+37^7+36^7+29^7+23^7+19^7+13^7+6^7+5^7=41^7+40^7+33^7+28^7+27^7+15^7+14^7+9^7+2^7+1^7. \quad (29)$$

Diophantine Equation—8th Powers

The 8.1.2 equation

$$A^8+B^8=C^8 \tag{1}$$

is a special case of FERMAT'S LAST THEOREM with $n=8$, and so has no solution. No 8.1.3, 8.1.4, 8.1.5, 8.1.6, 8.1.7, or 8.1.8 solutions are known. The smallest 8.1.9 is

$$1167^8=10948+1040^8+560^8+558^8$$
$$+366^8+348^8+284^8+271^8+190^8 \tag{2}$$

(N. Kuosa). The smallest 8.1.10 is

$$235^8=226^8+184^8+171^8+152^8+142^8$$
$$+66^8+58^8+34^8+16^8+6^8 \tag{3}$$

(N. Kuosa, PowerSum). The smallest 8.1.11 solution is

$$14^8+18^8+44^8+44^8+66^8+70^8+92^8+93^8$$
$$+96^8+106^8+112^8=125^8 \tag{4}$$

(Lander *et al.* 1967, Ekl 1998). The smallest 8.1.12 solution is

$$8^8+8^8+10^8+24^8+24^8+248+26^8+30^8+34^8$$
$$+44^8+52^8+63^8=65^8 \tag{5}$$

(Lander *et al.* 1967). The general identity

$$(2^{8k+4}+1)^8=(2^{8k+4}-1)^8+(2^{7k+4})^8+(2^{k+1})^8$$
$$+7\left[(2^{5k+3})^8+(2^{3k+2})^8\right] \tag{6}$$

gives a solution to the 8.1.17 equation (Lander *et al.* 1967).

No 8.2.2, 8.2.3, 8.2.4, 8.2.5, 8.2.6, or 8.2.7 solutions are known. The smallest 8.2.8 solution is

$$129^8+95^8=128^8+92^8+86^8+82^8+74^8+57^8+55^8$$
$$+20^8. \tag{7}$$

The smallest 8.2.9 solution is

$$2^8+7^8+8^8+16^8+17^8+20^8+20^8+24^8+24^8$$
$$=11^8+27^8 \tag{8}$$

(Lander *et al.* 1967, Ekl 1998).

No 8.3.3, 8.3.4, 8.3.5, or 8.3.6 solutions are known. The smallest 8.3.7 solution is

$$108^8+68^8+5^8$$
$$=102^8+88^8+88^8+52^8+37^8+26^8+6^8. \tag{9}$$

The smallest 8.3.8 solution is

$$6^8+12^8+16^8+16^8+38^8+38^8+40^8+47^8$$
$$=8^8+17^8+50^8 \tag{10}$$

(Lander *et al.* 1967, Ekl 1998).

No 8.4.4 solutions is known. The smallest 8.4.5 solution is

$$221^8+108^8+94^8+94^8$$
$$=195^8+194^8+188^8+126^8+38^8. \tag{11}$$

The smallest 8.4.6 solution is

$$47^8+29^8+12^8+5^8$$
$$=45^8+40^8+30^8+268+23^8+3^8 \tag{12}$$

(Ekl 1998). The smallest 8.4.7 solution is

$$7^8+9^8+16^8+22^8+22^8+28^8+34^8$$
$$=6^8+11^8+20^8+35^8 \tag{13}$$

(Lander *et al.* 1967).

The smallest 8.5.5 solutions are

$$43^8+20^8+11^8+10^8+1^8$$
$$=41^8+35^8+32^8+28^8+5^8 \tag{14}$$

$$42^8+41^8+35^8+9^8+6^8$$
$$=45^8+36^8+27^8+13^8+8^8 \tag{15}$$

$$63^8+63^8+31^8+15^8+6^8$$
$$=65^8+59^8+48^8+37^8+7^8 \tag{16}$$

$$75^8+47^8+39^8+26^8+6^8$$
$$=67^8+67^8+62^8+20^8+11^8 \tag{17}$$

$$77^8+76^8+71^8+42^8+28^8$$
$$=86^8+41^8+36^8+32^8+29^8 \tag{18}$$

$$90^8+81^8+10^8+4^8+3^8$$
$$=92^8+74^8+55^8+50^8+37^8 \tag{19}$$

$$93^8+65^8+65^8+41^8+13^8$$
$$=81^8+81^8+79^8+75^8+45^8 \tag{20}$$

$$89^8+87^8+28^8+14^8+14^8$$
$$=96^8+36^8+33^8+31^8+24^8 \tag{21}$$

$$93^8+90^8+32^8+18^8+9^8$$
$$=94^8+86^8+71^8+60^8+19^8 \tag{22}$$

$$104^8+73^8+36^8+17^8+3^8$$
$$=103^8+78^8+68^8+11^8+9^8 \tag{23}$$

$$103^8+86^8+58^8+11^8+8^8$$
$$=104^8+78^8+69^8+62^8+9^8 \tag{24}$$

$$108^8+101^8+88^8+45^8+1^8$$
$$=116^8+59^8+46^8+15^8+3^8 \tag{25}$$

$$116^8+92^8+79^8+33^8+25^8$$
$$=113^8+103^8+60^8+44^8+31^8 \tag{26}$$

$$123^8+97^8+71^8+10^8+2^8 = 125^8+77^8+48^8+37^8+26^8 \quad (27)$$

$$121^8+109^8+71^8+70^8+40^8 = 120^8+104^8+99^8+75^8+61^8 \quad (28)$$

$$127^8+43^8+26^8+10^8+3^8 = 123^8+105^8+69^8+42^8+14^8 \quad (29)$$

(Letac 1942, Lander *et al.* 1967, Ekl 1998). The smallest 8.5.6 solutions are

$$36^8+36^8+33^8+25^8+21^8 = 38^8+34^8+32^8+15^8+15^8+13^8 \quad (30)$$

$$39^8+33^8+32^8+25^8+19^8 = 37^8+35^8+35^8+17^8+16^8+2^8 \quad (31)$$

$$41^8+21^8+20^8+19^8+16^8 = 40^8+31^8+30^8+17^8+9^8+8^8 \quad (32)$$

$$43^8+34^8+24^8+8^8+1^8 = 42^8+37^8+28^8+16^8+16^8+15^8 \quad (33)$$

$$44^8+42^8+24^8+17^8+4^8 = 47^8+20^8+18^8+8^8+6^8+6^8 \quad (34)$$

$$49^8+29^8+22^8+1^8+1^8 = 47^8+42^8+26^8+23^8+17^8+5^8 \quad (35)$$

$$46^8+46^8+33^8+30^8+9^8 = 45^8+45^8+36^8+36^8+34^8+32^8 \quad (36)$$

$$51^8+48^8+39^8+21^8+10^8 = 53^8+45^8+25^8+22^8+22^8+6^8 \quad (37)$$

$$55^8+37^8+19^8+19^8+18^8 = 51^8+50^8+35^8+26^8+11^8+9^8 \quad (38)$$

$$58^8+17^8+13^8+10^8+7^8 = 56^8+45^8+41^8+40^8+8^8+1^8 \quad (39)$$

$$55^8+53^8+24^8+21^8+2^8 = 52^8+52^8+50^8+25^8+17^8+7^8 \quad (40)$$

$$58^8+51^8+17^8+11^8+11^8 = 60^8+37^8+34^8+29^8+23^8+3^8 \quad (41)$$

$$54^8+51^8+51^8+43^8+4^8 = 59^8+46^8+41^8+30^8+17^8+2^8 \quad (42)$$

$$58^8+53^8+35^8+19^8+17^8 = 61^8+30^8+25^8+23^8+16^8+1^8 \quad (43)$$

$$61^8+29^8+28^8+27^8+26^8 = 57^8+52^8+48^8+17^8+14^8+5^8 \quad (44)$$

$$58^8+51^8+49^8+8^8+6^8 = 61^8+44^8+32^8+26^8+10^8+1^8 \quad (45)$$

$$62^8+53^8+38^8+32^8+23^8 = 61^8+52^8+50^8+34^8+24^8+1^8 \quad (46)$$

$$59^8+57^8+47^8+40^8+8^8 = 62^8+52^8+45^8+17^8+15^8+2^8 \quad (47)$$

$$63^8+62^8+55^8+43^8+27^8 = 65^8+59^8+56^8+17^8+13^8+10^8 \quad (48)$$

(Ekl 1998).

Moessner and Gloden (1944) found solutions to the 8.6.6 equation. The smallest 8.6.6 solution is

$$3^8+6^8+8^8+10^8+15^8+23^8 = 5^8+9^8+9^8+12^8+20^8+22^8 \quad (49)$$

(Lander *et al.* 1967). Ekl (1998) mentions but does not list 204 primitive solutions to the 8.6.6 equation. Moessner and Gloden (1944) found solutions to the 8.6.7 equation.

Parametric solutions to the 8.7.7 equation were given by Moessner (1947) and Gloden (1948). The smallest 8.7.7 solution is

$$1^8+3^8+5^8+6^8+6^8+8^8+13^8 = 4^8+7^8+9^8+9^8+10^8+11^8+12^8 \quad (50)$$

(Lander *et al.* 1967).

Sastry (1934) used the smallest 17– solution to give a parametric 8.8.8 solution. The smallest 8.8.8 solution is

$$1^8+3^8+7^8+7^8+7^8+10^8+10^8+12^8 = 4^8+5^8+5^8+6^8+6^8+11^8+11^8+11^8 \quad (51)$$

(Lander *et al.* 1967).

Letac (1942) found solutions to the 8.9.9 equation.

Moessner and Gloden (1944) found the 8.9.10 solution

$$54^8+53^8+46^8+37^8+29^8+23^8+22^8+6^8+5^8 = 55^8++50^8+49^8+33^8+32^8+26^8+18^8+9^8+2^8 +1^8. \quad (52)$$

Diophantine Equation—9th Powers

The 9.1.2 equation

$$A^9 = B^9 + C^9 \tag{1}$$

is a special case of FERMAT'S LAST THEOREM with $n = 9$, and so has no solution. No 9.1.3, 9.1.4, 9.1.5, 9.1.6, 9.1.7, 9.1.8, 9.1.9, 9.1.10, or 9.1.11 solutions are known. The smallest 9.1.12 solution is

$$103^9 = 91^9 + 91^9 + 89^9 + 71^9 + 68^9 + 65^9 + 43^9 + 42^9 + 19^9 + 16^9 + 13^9 + 5^9. \tag{2}$$

To 9.1.13 solution is known. The smallest 9.1.14 solution is

$$66^9 = 63^9 + 54^9 + 51^9 + 49^9 + 38^9 + 35^9 + 29^9 + 24^9 + 21^9 + 12^9 + 10^9 + 7^9 + 2^9 + 1^9 \tag{3}$$

(Ekl 1998).

No 9.2.2, 9.2.3, 9.2.4,. 9.2.5, 9.2.6, 9.2.7, 9.2.8, or 9.2.9 solutions are known. A 9.2.10 solution is given by

$$121^9 + 2\cdot 116^9 + 115^9 + 89^9 + 52^9 + 28^9 + 26^9 + 14^9 + 9^9 = 137^9 + 69^9 \tag{4}$$

(L. Morelli 1999, PowerSum). No 9.2.11 solutions are known. The smallest 9.2.12 solution is

$$4\cdot 2^9 + 2\cdot 3^9 + 4^9 + 7^9 + 16^9 + 17^9 + 2\cdot 19^9 = 15^9 + 21^9 \tag{5}$$

(Lander *et al.* 1967, Ekl 1998). There are no known 9.1.13 or 9.1.14 solutions. The smallest 9.1.15 solution is

$$2^9 + 2^9 + 4^9 + 6^9 + 6^9 + 7^9 + 9^9 + 9^9 + 10^9 + 15^9 + 18^9 + 21^9 + 21^9 + 23^9 + 23^9 = 26^9 \tag{6}$$

(Lander *et al.* 1967).

There are no known 9.3.3, 9.3.4, 9.3.5, 9.3.6, 9.3.7, or 9.3.8 solutions. The smallest 9.3.9 solution is

$$2\cdot 38^9 + 3^9 = 41^9 + 23^9 + 2\cdot 20^9 + 18^9 + 2\cdot 13^9 + 12^9 + 9^9 \tag{7}$$

(Ekl 1998). There is no known 9.3.10 solution. The smallest 9.3.11 solution is

$$2^9 + 3^9 + 6^9 + 7^9 + 9^9 + 9^9 + 19^9 + 19^9 + 21^9 + 25^9 + 29^9 = 13^9 + 16^9 + 30^9 \tag{8}$$

(Lander *et al.* 1967).

There are no known 9.4.4 or 9.4.5 solutions are known. The smallest 9.4.6 solution is

$$90^9 + 64^9 + 35^9 + 35^9 = 86^9 + 80^9 + 62^9 + 43^9 + 27^9 + 16^9. \tag{9}$$

There are no known 9.4.7 or 9.4.8 solutions. The smallest 9.4.9 solution is

$$38^9 + 31^9 + 12^9 + 2^9 = 36^9 + 2\cdot 32^9 + 30^9 + 15^9 + 13^9 + 8^9 + 4^9 + 3^9 \tag{10}$$

(Ekl 1998). The smallest 9.4.10 solutions are

$$2^9 + 6^9 + 6^9 + 9^9 + 10^9 + 11^9 + 14^9 + 18^9 + 19^9 + 19^9 = 5^9 + 12^9 + 16^9 + 21^9 \tag{11}$$

(Lander *et al.* 1967).

The smallest 9.5.5 solution is

$$192^9 + 101^9 + 91^9 + 30^9 + 26^9 = 180^9 + 175^9 + 116^9 + 17^9 + 12^9. \tag{12}$$

There is no known 9.5.6 solution. The smallest 9.5.7 solution is

$$35^9 + 26^9 + 2\cdot 15^9 + 12^9 = 33^9 + 32^9 + 24^9 + 16^9 + 14^9 + 8^9 + 6^9 \tag{13}$$

(Ekl 1998). There are no known 9.5.8, 9.5.9, or 9.5.10 solutions. The smallest 9.5.11 solution is

$$3^9 + 5^9 + 5^9 + 9^9 + 9^9 + 12^9 + 15^9 + 15^9 + 16^9 + 21^9 + 21^9 = 7^9 + 8^9 + 14^9 + 20^9 + 22^9 \tag{14}$$

(Lander *et al.* 1967).

The smallest 9.6.6 solutions are

$$23^9 + 18^9 + 14^9 + 13^9 + 13^9 + 1^9 = 22^9 + 21^9 + 15^9 + 10^9 + 9^9 + 5^9 \tag{15}$$

$$31^9 + 23^9 + 21^9 + 14^9 + 9^9 + 2^9 = 29^9 + 29^9 + 15^9 + 11^9 + 10^9 + 6^9 \tag{16}$$

$$46^9 + 44^9 + 27^9 + 27^9 + 27^9 + 9^9 = 48^9 + 39^9 + 23^9 + 15^9 + 13^9 + 12^9 \tag{17}$$

$$47^9 + 47^9 + 22^9 + 22^9 + 12^9 + 4^9 = 50^9 + 39^9 + 35^9 + 13^9 + 10^9 + 7^9 \tag{18}$$

$$54^9 + 52^9 + 48^9 + 47^9 + 46^9 + 14^9 = 60^9 + 18^9 + 17^9 + 16^9 + 15^9 + 15^9 \tag{19}$$

$$70^9 + 44^9 + 36^9 + 33^9 + 19^9 + 4^9 = 64^9 + 63^9 + 57^9 + 47^9 + 22^9 + 13^9 \tag{20}$$

$$68^9 + 58^9 + 50^9 + 46^9 + 41^9 + 7^9 = 70^9 + 48^9 + 26^9 + 25^9 + 23^9 + 18^9 \tag{21}$$

(Lander *et al.* 1967, Ekl 1998).

Ekl (1998) mentions but does not list nine primitive solutions to the 9.7.7 equation.

Moessner (1947) gives a parametric solution to the 9.10.10 equation.

Palamá (1953) gave a solution to the 9.11.11 equation.

Moessner and Gloden (1944) give the 9.11.12 solution

$$72^9+67^9+66^9+53^9+43^9+37^9+35^9+29^9+19^9 +6^9+5^9 = 71^9+70^9+63^9+55^9+40^9+39^9+33^9+32^9 +17^9+9^9+2^9+1^9. \quad (22)$$

Diophantine Equation—nth Powers

The 2– equation

$$A^n+B^n+=C^n \quad (1)$$

is a special case of FERMAT'S LAST THEOREM and so has no solutions for $n \geq 3$. Lander *et al.* (1967) give a table showing the smallest n for which a solution to

$$x_1^k+x_2^k+\ldots+x_m^k=y_1^k+y_2^k+\ldots+y_n^k, \quad (2)$$

with $1 \leq m \leq n$ is known. An updated table is given below; a more extensive table may be found at the PowerSum web site.

	k								
m	2	3	4	5	6	7	8	9	10
1	2	3	3	4	7	8	11	15	23
2	2	2	2	4	7	8	9	12	19
3				3	3	7	8	11	24
4						4	7	10	23
5						5	5	11	16
6								6	27
7									7

Take the results from the RAMANUJAN 6–0– IDENTITY that for $ad=bc$, with

$$F_{2m}(a,b,c,d) = (a+b+c)^{2m}+(b+c+d)^{2m}-(c+d+a)^{2m} -(d+a+b)^{2m}+(a-d)^{2m}-(b-c)^{2m} \quad (3)$$

and

$$f_{2m}(x,y)=(1+x+y)^{2m}+(x+y+xy)^{2m}-(y+xy+1)^{2m} -(xy+1+x)^{2m}+(1-xy)^{2m}-(x-y)^{2m}, \quad (4)$$

then

$$F_{2m}(a,b,c,d)=a^{2m}f_{2m}(x,y). \quad (5)$$

Using

$$f_2(x,y)=0 \quad (6)$$

$$f_4(x,y)=0 \quad (7)$$

now gives

$$(a+b+c)^n+(b+c+d)^n+(a-d)^n = (c+d+a)^n+(d+a+b)^n+(b-c)^n \quad (8)$$

for $n=2$ or 4.

Diophantine Quadruple

DIOPHANTINE SET

Diophantine Set

A set S of POSITIVE INTEGERS is said to be Diophantine IFF there exists a POLYNOMIAL Q with integral

coefficients in $m \geq 1$ indeterminates such that

$$S = \{Q(x_1, ..., x_m) \geq 1 : x_1 \geq 1, ..., x_m \geq 1\}.$$

It has been proved that the set of PRIME NUMBERS is a Diophantine set.

References

Ribenboim, P. *The New Book of Prime Number Records.* New York: Springer-Verlag, pp. 189–92, 1995.

Diophantus Property

A set of m distinct POSITIVE INTEGERS $S = \{a_1, ..., a_m\}$ satisfies the Diophantus property $D(n)$ of order n (a positive integer) if, for all $i, j = 1, ..., m$ with $i \neq j$,

$$a_i a_j + n = b_{ij}^2, \tag{1}$$

the b_{ij}s are INTEGERS. The set S is called a Diophantine n-tuple.

Diophantine 1-doubles are abundant: (1, 3), (2, 4), (3, 5), (4, 6), (5, 7), (1, 8), (3, 8), (6, 8), (7, 9), (8, 10), (9, 11), ... (Sloane's A050269 and A050270). Diophantine 1-triples are less abundant: (1, 3, 8), (2, 4, 12), (1, 8, 15), (3, 5, 16), (4, 6, 20), ... (Sloane's A050273, A050274, and A050275).

Fermat found the smallest Diophantine 1-quadruple: $\{1, 3, 8, 120\}$ (Davenport and Baker 1969, Jones 1976). There are no others with largest term ≤ 200, and Davenport and Baker (1969) showed that if $c+1$, $3c+1$, and $8c+1$ are all squares, then $c = 120$. Jones (1976) derived an infinite sequence of polynomials $S = \{x, x+2, c_1(x), c_2(x), ...\}$ such that the product of any two, increased by 1, is the square of a polynomial. Letting $c_{-1}(x) = c_0(x) = 0$, then the general $c_k(x)$ is given by the RECURRENCE RELATION

$$c_k = (4x^2 + 8x + 2)c_{k-1} - c_{k-2} + 4(x+1). \tag{2}$$

The first few c_k are

$$c_1 = 4(x+1)$$

$$c_2 = 4(3 + 11x + 12x^2 + 4x^3)$$

$$c_3 = 8(3 + 23x + 62x^2 + 74x^3 + 40x^4 + 8x^5).$$

Letting $x = 1$ gives the sequence $s_n = 1$, 3, 8, 120, 1680, 23408, 326040, ... (Sloane's A051047), for which $\sqrt{s_n s_{n+1} + 1}$ is 2, 5, 31, 449, 6271, 87361, ... (Sloane's A051048).

General $D(1)$ quadruples are

$$\{F_{2n}, F_{2n+2}, F_{2n+4}, 4F_{2n+1}F_{2n+2}F_{2n+3},\} \tag{3}$$

where F_n are FIBONACCI NUMBERS, and

$$\{n, n+2, 4n+4, 4(n+1), (2n+1)(2n+3)\}. \tag{4}$$

The quadruplet

$$\{2F_{n-1}, 2F_{n+1}, 2F_n^3 F_{n+1} F_{n+2},$$

$$2F_{n+1}F_{n+2}F_{n+3}(2F_{n+1}^2 - F_n^2)\} \tag{5}$$

is $D(F_n^2)$ (Dujella 1996). Dujella (1993) showed there exist no Diophantine quadruples $D(4k+2)$.

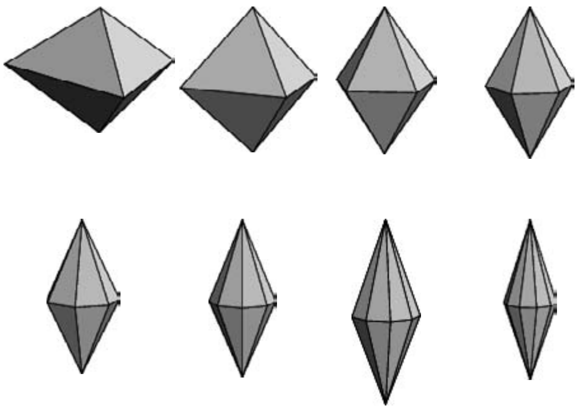
Diophantus's Riddle

"Diophantus's youth lasts 1/6 of his life. He grew a beard after 1/12 more of his life. After 1/7 more of his life, Diophantus married. Five years later, he had a son. The son lived exactly half as long as his father, and Diophantus died just four years after his son's death. All of this totals the years Diophantus lived."

Let D be the number of years Diophantus lived, and let S be the number of years his son lived. Then the above word problem gives the two equations

$$D = \left(\frac{1}{6} + \frac{1}{12} + \frac{1}{7}\right)D + 5 + S + 4$$



$$S = \frac{1}{2}D.$$

Solving this simultaneously gives $S = 42$ as the age of the son and $D = 84$ as the age of Diophantus.

Dipyramid

Two PYRAMIDS symmetrically placed base-to-base, also called a BIPYRAMID. The dipyramids are DUALS of the regular PRISMS.

Consider the dipyramids generated by taking the duals of the n-PRISMS. The edge lengths of the base S_n^b and slant edges S_n^s, half-height (half the distance from peak to peak) h_n, surface areas S_n and volumes V_n (after scaling so that the *smallest* edge length is 1) are given by

$$S_3^b, S_3^s = 2, \frac{4}{3} \quad (1)$$

$$h_3 = \frac{2}{3} \quad (2)$$

$$S_3 = \frac{9}{8}\sqrt{7} \quad (3)$$

$$V_3 = \frac{3}{16}\sqrt{3} \quad (4)$$

$$s_4^b, s_4^s = \sqrt{2}, \sqrt{2} \quad (5)$$

$$h_4 = 1 \quad (6)$$

$$S_4 = 2\sqrt{3} \quad (7)$$

$$V_4 = \frac{1}{3}\sqrt{2} \quad (8)$$

$$S_4^b, S_4^s = \sqrt{5} - 1, \frac{4}{5}\sqrt{5} \quad (9)$$

$$h_4 = \frac{1}{2}\sqrt{2} \quad (10)$$

$$S_4 = 2\sqrt{3} \quad (11)$$

$$V_4 = \frac{1}{3}\sqrt{2} \quad (12)$$

$$S_5^b, S_5^s = \sqrt{5} - 1, \frac{4}{5}\sqrt{5} \quad (13)$$

$$h_5 = \frac{1}{5}(5 + \sqrt{5}) \quad (14)$$

$$S_5 = \frac{1}{2}\sqrt{95 + 40\sqrt{5}} \quad (15)$$

$$V_5 = \frac{1}{6}\sqrt{\frac{1}{2}\left(65 + 29\sqrt{5}\right)} \quad (16)$$

$$S_6^b, S_6^s = \frac{2}{3}\sqrt{3}, \frac{4}{3}\sqrt{3} \quad (17)$$

$$h_6 = 2 \quad (18)$$

$$S_6 = 3\sqrt{15} \quad (19)$$

$$V_6 = 3 \quad (20)$$

$$S_8^b, S_8^s = \sqrt{2\left(2 - \sqrt{2}\right)}, 2\sqrt{2 + \sqrt{2}} \quad (21)$$

$$h_8 = 2 + \sqrt{2} \quad (22)$$

$$S_8 = 4\sqrt{23 + 16\sqrt{2}} \quad (23)$$

$$V_8 = \frac{2}{3}\sqrt{2\left(58 + 41\sqrt{2}\right)} \quad (24)$$

$$S_{10}^b, S_{10}^s = \sqrt{\frac{2}{5}\left(5 - \sqrt{5}\right)}, 4\sqrt{\frac{1}{5}\left(5 + 2\sqrt{5}\right)} \quad (25)$$

$$h_{10} = 3 + \sqrt{5} \quad (26)$$

$$S_{10} = 5\sqrt{55 + 24\sqrt{5}} \quad (27)$$

$$V_{10} = \frac{5}{6} + \left(15 + 7\sqrt{5}\right). \quad (28)$$

JOHNSON SOLID J_{12} is a triangular dipyramid, the OCTAHEDRON is a square dipyramid, and JOHNSON SOLID J_{13} is a pentagonal dipyramid.

Dirac Delta Function

DELTA FUNCTION

Dirac Distribution

DELTA FUNCTION

Dirac Equation

The quantum electrodynamical law which applies to spin-1/2 particles and is the relativistic generalization of the SCHRÖDINGER EQUATION. In $3+1$ dimensions (three space dimensions and one time dimension), it is given by

$$\frac{ih}{c}\frac{\partial \psi}{\partial t} = \left[\alpha_x p_x + \alpha_y p_y + \alpha_z p_z + \alpha_4 (mc)\right]\psi, \qquad (1)$$

where h is h-bar, c is the speed of light, ψ is the wavefunction , m is the mass of the particle, α_i are the DIRAC MATRICES, σ_i are PAULI SPIN MATRICES, and

$$p_i = \begin{bmatrix} p_i & 0 & 0 & 0 \\ 0 & p_i & 0 & 0 \\ 0 & 0 & p_i & 0 \\ 0 & 0 & 0 & p_i \end{bmatrix}. \qquad (2)$$

In $1+1$ dimensions, the Dirac equation is the system of PARTIAL DIFFERENTIAL EQUATIONS

$$u_t + v_x + imu + 2i\lambda\left(|u|^2 - |v|^2\right)u = 0 \qquad (3)$$

$$v_t + u_x + imv + 2i\lambda\left(|v|^2 - |u|^2\right)v = 0 \qquad (4)$$

(Alvarez *et al.* 1982; Zwillinger 1997, p. 137);

Dirac Gamma Matrices

DIRAC MATRICES

Dirac Matrices

The Dirac matrices are a class of 4×4 matrices which arise in quantum electrodynamics. There are a variety of different symbols used, and Dirac matrices are also known as gamma matrices or Dirac gamma matrices.

The Dirac matrices are defined as the 4×4 matrices

$$\sigma_i = \mathsf{I}_2 \otimes \sigma_{i,\text{Pauli}} \qquad (1)$$

$$\rho_i = \sigma_{i,\text{Pauli}} \otimes \mathsf{I}_2, \qquad (2)$$

where σ_i, Rauli are the (2×2) PAULI MATRICES, $_2$ is the (2×2) IDENTITY MATRIX, $i = 1, 2, 3$, and $\mathsf{A} \otimes \mathsf{B}$ is the MATRIX DIRECT PRODUCT. Explicitly, this set of Dirac matrices is then given by

$$\mathsf{I} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \qquad (3)$$

$$\sigma_1 = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} \qquad (4)$$

$$\sigma_2 = \begin{bmatrix} 0 & -i & 0 & 0 \\ i & 0 & 0 & 0 \\ 0 & 0 & 0 & -i \\ 0 & 0 & i & 0 \end{bmatrix} \qquad (5)$$

$$\sigma_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \qquad (6)$$

$$\rho_1 = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \qquad (7)$$

$$\rho_2 = \begin{bmatrix} 0 & 0 & -i & 0 \\ 0 & 0 & 0 & -i \\ i & 0 & 0 & 0 \\ 0 & i & 0 & 0 \end{bmatrix} \qquad (8)$$

$$\rho_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \qquad (9)$$

These matrices satisfy the anticommutation identities

$$\sigma_i\sigma_j + \sigma_j\sigma_i = 2\delta_{ij}\mathsf{I} \qquad (10)$$

$$\rho_i\rho_j + \rho_j\rho_i = 2\delta_{ij}\mathsf{I}, \qquad (11)$$

where δ_{ij} is the KRONECKER DELTA, the commutation identity

$$\left[\sigma_i, \rho_j\right] = \sigma_i\rho_j + \sigma_j\rho_i = 0, \qquad (12)$$

and are cyclic under permutations of indices

$$\sigma_i\sigma_i = i\sigma_k \qquad (13)$$

$$\rho_i\rho_i = i\rho_k. \qquad (14)$$

A total of 16 Dirac matrices can be defined via

$$\mathsf{E}_{ij} = \sigma_i\rho_j \qquad (15)$$

for $i, j = 0,\ 1,\ 2,\ 3$ and where $\sigma_0 = \rho_0 \equiv \mathsf{I}$. These matrices satisfy

1. $|\mathsf{E}_{ij}|=1$, where $|\mathsf{A}|$ is the DETERMINANT,
2. $\mathsf{E}_{ij}^2=\mathsf{I}$,
3. $\mathsf{E}_{ij}=\mathsf{E}_{ij}^*$, where A^* denotes the ADJOINT MATRIX, making them Hermitian, and therefore unitary,
4. $\mathrm{Tr}(\mathsf{E}_{ij})=0$, except $\mathrm{Tr}(\mathsf{E}_{00})=4$,
5. Any two E_{ij} multiplied together yield a Dirac matrix to within a multiplicative factor of -1 or $\pm i$,
6. The E_{ij} are linearly independent,
7. The E_{ij} form a complete set, i.e., any 4×4 constant matrix may be written as

$$\mathsf{A}=\sum_{i,j=0}^{3} c_{ij}\mathsf{E}_{ij}, \tag{16}$$

where the c_{ij} are real or complex and are given by

$$c_{mn}=\frac{1}{4}\mathrm{Tr}(\mathsf{A}\mathsf{E}_{mn}) \tag{17}$$

(Arfken 1985).

Dirac's original matrices were written α_i and were defined by

$$\alpha_i=\mathsf{E}_{1i}=\rho_1\sigma_i \tag{18}$$

$$\alpha_4=\mathsf{E}_{30}=\rho_3, \tag{19}$$

for $i=1, 2, 3$, giving

$$\alpha_1=\mathsf{E}_{11}=\begin{bmatrix}0&0&0&1\\0&0&1&0\\0&1&0&0\\1&0&0&0\end{bmatrix} \tag{20}$$

$$\alpha_2=\mathsf{E}_{12}=\begin{bmatrix}0&0&0&-i\\0&0&i&0\\0&-i&0&0\\i&0&0&0\end{bmatrix} \tag{21}$$

$$\alpha_3=\mathsf{E}_{13}=\begin{bmatrix}0&0&1&0\\0&0&0&-1\\1&0&0&0\\0&-1&0&0\end{bmatrix} \tag{22}$$

$$\alpha_4=\mathsf{E}_{30}=\begin{bmatrix}1&0&0&1\\0&1&0&0\\0&0&-1&0\\0&0&0&-1\end{bmatrix}. \tag{23}$$

The additional matrix

$$\alpha_5=\mathsf{E}_{20}=\rho_2=\begin{bmatrix}0&0&-i&0\\0&0&0&-i\\i&0&0&0\\0&i&0&0\end{bmatrix} \tag{24}$$

is sometimes defined.

A closely related set of Dirac matrices is defined by

$$\gamma_{\mathrm{i}}=\begin{bmatrix}0&\sigma_i\\-\sigma_i&0\end{bmatrix} \tag{25}$$

$$\gamma_4=\begin{bmatrix}\mathsf{I}&0\\2\mathsf{I}&-\mathsf{I}\end{bmatrix} \tag{26}$$

for $i=1, 2, 3$ (Goldstein 1980). Instead of γ_4, γ_0, is commonly used. Unfortunately, there are two different conventions for its definition, the "chiral basis"

$$\gamma_0=\begin{matrix}0&\mathsf{I}\\\mathsf{I}&0\end{matrix}. \tag{27}$$

and the "Dirac basis"

$$\gamma_0=\begin{matrix}\mathsf{I}&0\\0&-\mathsf{I}\end{matrix}. \tag{28}$$

Other sets of Dirac matrices are sometimes defined as

$$y_i=\mathsf{E}_{2i} \tag{29}$$

$$y_4=\mathsf{E}_{30} \tag{30}$$

$$y_5=-\mathsf{E}_{10} \tag{31}$$

and

$$\delta_i=\mathsf{E}_{3i} \tag{32}$$

for $i=1, 2, 3$ (Arfken 1985).

Any of the 15 Dirac matrices (excluding the identity matrix) commute with eight Dirac matrices and anticommute with the other eight. Let $\mathsf{M}\equiv\frac{1}{2}(1+\mathsf{E}_{ij})$, then

$$\mathsf{M}^2=\mathsf{M} \tag{33}$$

(Arfken 1985, p. 216). In addition

$$\begin{bmatrix}\alpha_1\\\alpha_2\\\alpha_3\end{bmatrix}\times\begin{bmatrix}\alpha_1\\\alpha_2\\\alpha_3\end{bmatrix}=2i\sigma. \tag{34}$$

The products of α_i and y_i satisfy

$$\alpha_1\alpha_2\alpha_3\alpha_4\alpha_5=1 \tag{35}$$

$$y_1y_2y_3y_4y_5=1. \tag{36}$$

The 16 Dirac matrices form six anticommuting sets of five matrices each:

1. $\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5$,
2. y_1, y_2, y_3, y_4, y_5,
3. $\delta_1, \delta_2, \delta_3, \rho_1, \rho_2$,
4. $\alpha_1, y_1, \delta_1, \sigma_2, \sigma_3$,
5. $\alpha_2, y_2, \delta_2, \sigma_1, \sigma_3$,
6. $\alpha_3, y_3, \delta_3, \sigma_1, \sigma_2, .$

Dirac Notation

A notation invented by Dirac which is very useful in quantum mechanics. The notation defines the "KET" vector, denoted $|\psi\rangle$, and its transpose, called the "BRA" vector and denoted $\langle\psi|$.. The "bracket" is then defined by $\langle\phi|\psi\rangle$.. Dirac notation satisfies the identities

$$\langle\phi|\tilde{O}|\psi\rangle \equiv \langle\phi|\tilde{O}\psi\rangle$$

$$\langle\phi|\psi\rangle \equiv \int_{-\infty}^{\infty} \bar{\phi}\psi dx,$$

where $\bar{\psi}$ is the COMPLEX CONJUGATE.

See also ANGLE BRACKET, BRA, DIFFERENTIAL K-FORM, KET, L2-SPACE, ONE-FORM

Dirac Operator

The operator $D = -i(d + d^*)$, where d^* is the ADJOINT.

Dirac's Theorem

A GRAPH with $n \geq 3$ VERTICES in which each VERTEX has VERTEX DEGREE $\geq n/2$ has a HAMILTONIAN CIRCUIT.

See also HAMILTONIAN CIRCUIT

Direct Analytic Continuation

If *(f, U)* and *(g, V)* are FUNCTIONS ELEMENTS, then *(g, V)* is a direct analytic continuation of *(f, U)* if $U \cap V \neq 0\emptyset$ and f and G are equal on $U \cap V$..

See also ANALYTIC CONTINUATION, GLOBAL ANALYTIC CONTINUATION

Direct Product

The direct product is defined for a number of classes of algebraic objects, including GROUPS, RINGS, and MODULES. In each case, the direct product of an algebraic object is given by the CARTESIAN PRODUCT of its elements, considered as sets, and its algebraic operations are defined componentwise. For instance, the direct product of two VECTOR SPACES of DIMENSIONS n and m is a VECTOR SPACE of DIMENSION $n+m$.

Direct products satisfy the property that, given maps $\alpha : S \to A$ and $\beta : S \to B$, there exists a unique map $S \to A \times B$ given by $(\alpha(s), \beta(s))$.. The notion of map is determined by the CATEGORY, and this definition extends to other CATEGORIES such as TOPOLOGICAL SPACES. Note that no notion of commutativity is necessary, in contrast to the case for the COPRODUCT. In fact, when A and B are ABELIAN, as in the cases of MODULES (e.g., VECTOR SPACES) or ABELIAN GROUPS) (which are MODULES over the integers), then the DIRECT SUM $A \oplus B$ is well-defined and is the same as the direct product. Although the terminology is slightly confusing because of the distinction between the elementary operations of addition and multiplication, the term "direct sum" is used in these cases instead of "direct product" because of the implicit connotation that addition is always commutative.

Note that direct products and DIRECT SUMS differ for infinite indices. An element of the DIRECT SUM is zero for all but a finite number of entries, while an element of the direct product can have all nonzero entries.

Some other unrelated objects are sometimes also called a direct product. For example, the TENSOR DIRECT PRODUCT is the same as the TENSOR PRODUCT, in which case the dimensions multiply instead of add. Here, "direct" may be used to distinguish it from the EXTERNAL TENSOR PRODUCT.

Direct Proportion

DIRECTLY PROPORTIONAL

Direct Search Factorization

Direct search factorization is the simplest (and most simple-minded) PRIME FACTORIZATION ALGORITHM. It consists of searching for factors of a number by systematically performing TRIAL DIVISIONS, usually using a sequence of increasing numbers. Multiples of small PRIMES are commonly excluded to reduce the number of trial DIVISORS, but just including them is sometimes faster than the time required to exclude them. Direct search factorization is very inefficient, and can be used only with fairly small numbers.

When using this method on a number n, only DIVISORS up to $\lfloor\sqrt{n}\rfloor$ (where $\lfloor x\rfloor$ is the FLOOR FUNCTION) need to be tested. This is true since if all INTEGERS less than this had been tried, then

$$\frac{n}{\lfloor\sqrt{n}\rfloor + 1} < \sqrt{n}. \qquad (1)$$

In other words, all possible FACTORS have had their COFACTORS already tested. It is also true that, when the smallest PRIME FACTOR p of n is $> \sqrt[3]{n}$, then its COFACTOR m (such that $n = pm$) must be PRIME. To prove this, suppose that the smallest p is $> \sqrt[3]{n},$. If $m = ab$, then the smallest value a and b could assume is p. But then

$$n = pm = pab = p^3 > n, \qquad (2)$$

which cannot be true. Therefore, m must be PRIME, so

$$n = p_1 p_2 \qquad (3)$$

See also PRIME FACTORIZATION ALGORITHMS, TRIAL DIVISION

Direct Sum

The direct sum $A \oplus B$ of two sets of integers A and B consists of the set $\{a + b : a \in \mathrm{A}, b \in \mathrm{B}\}$, and can be generalized to an arbitrary number of sets $A \oplus B \oplus \cdots$ in the obvious way. For example, the direct sum of $A = \{1, 2\}$, $B = \{1, 2\}$, and $C = \{2, 3\}$ is $A \oplus B \oplus C = \{4, 5, 5, 6, 5, 6, 6, 7\}$.. The direct sum of a sequence of sets l can be implemented in *Mathematica* as follows.

```
DirectSum[l__] := Flatten[Outer[Plus, l]]
```

The significant property of the direct sum is that it is the COPRODUCT in the CATEGORY of MODULES (i.e., a MODULE DIRECT SUM). This general definition gives as a consequence the definition of the direct sum $A \oplus B$ of ABELIAN GROUPS A and B (since they are $\mathbb{Z}$-modules, i.e., MODULES over the INTEGERS) and the direct sum of VECTOR SPACES (since they are MODULES over a FIELD). Note that the direct sum of Abelian groups is the same as the GROUP DIRECT PRODUCT, but that the term direct sum is not used for groups which are NON-ABELIAN.

Note that DIRECT PRODUCTS and direct sums differ for infinite indices. An element of the direct sum is zero for all but a finite number of entries, while an element of the DIRECT PRODUCT can have all nonzero entries.

See also ABELIAN GROUP, DIRECT PRODUCT, GROUP DIRECT PRODUCT, MATRIX DIRECT SUM, MODULE, MODULE DIRECT SUM

Direct Variation

DIRECTLY PROPORTIONAL

Directed Acyclic Graph

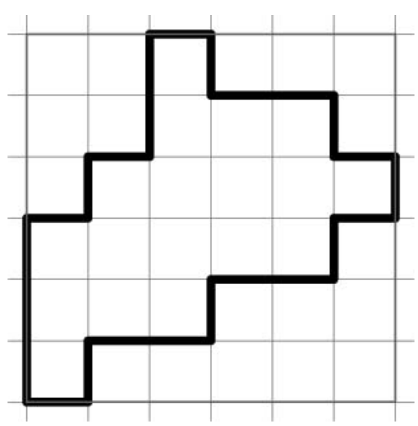
ACYCLIC DIGRAPH

Directed Angle

The symbol $\measuredangle ABC$ denotes the directed angle from AB to BC, which is the signed angle through which AB must be rotated about B to coincide with BC. Four points $ABCD$ lie on a CIRCLE (i.e., are CONCYCLIC) IFF $\measuredangle ABC = \measuredangle ADC$.. It is also true that

$$\measuredangle l_1 l_2 + \measuredangle l_2 l_1 = 0° \text{ or } 360°.$$

Three points A, B, and C are COLLINEAR IFF $\measuredangle ABC = 0 or 180.$ or $180°$. For any four points, A, B, C, and D,



$$\measuredangle ABC + \measuredangle CDA = \measuredangle BAD + \measuredangle DCB.$$

See also ANGLE, COLLINEAR, CONCYCLIC, MIQUEL EQUATION

Directed Convex Polyomino

A CONVEX POLYOMINO containing at least one edge of its minimal bounding rectangle. The perimeter and area generating function for directed polygons of width m, height n, and area q is given by

$$G(x, y, q) = \sum_{x \geq 1} \sum_{y \geq 1} \sum_{q \geq 1} C(m, n, a) x^m y^n q^n$$
$$= y \frac{R(x) - \hat{N}(x)}{N(x)} \qquad (1)$$

where

$$N(x) = \sum_{n \geq 0} \frac{(-1)^n x^n q^{\binom{n+1}{2}}}{(q)_n (yq)_n} \quad (2)$$

$$\hat{N}(x) = \sum_{n \geq 1} \frac{(-1)^n x^n q^{\binom{n+1}{2}}}{(q)_{n-1} (yq)_n} \quad (3)$$

$$R(x) = y \sum_{n \geq 2} \left[\frac{x^n q^n}{(yq)_n} \left(\frac{\sum_{m=0}^{n-2} (-1)^m q \binom{m+2}{2}}{(q)_m (yq^{m+1})_{n-m-1}} \right) \right] \quad (4)$$

(Bousquet-Mélou 1992).

The anisotropic perimeter generating function for directed convex polygons of width x and height y is given by

$$G(x,y) = \sum_{x \geq 1} \sum_{y \geq 1} C(m,n) x^m y^n = \frac{xy}{\sqrt{\Delta(x,y)}}, \quad (5)$$

where

$$\Delta(x,y) = 1 - 2x - 2y - 2xy + x^2 + y^2$$

$$= (1-y)^2 \left[1 - \frac{x(2+2y-x)}{(1-y)^2} \right] \quad (6)$$

(Lin and Chang 1988, Bousquet 1992, Bousquet-Mélou *et al.* 1999). This can be solved to explicitly give

$$C(m,n) = \binom{m+n-2}{m-1} \binom{m+n-2}{n-1} \quad (7)$$

(Bousquet-Mélou 1992). Expanding the generating function gives

$$G(x,y) = \sum_{m \geq 1} H_m(y) x^m \quad (8)$$

$$= \frac{y}{1-y} x + \frac{y(1+y)}{(1-y)^3} x^2 + \frac{y(1+4y+y^2)}{(1-y)^5} x^3 + \ldots \quad (9)$$

$$= (y + y^2 + y^3 + y^4 + y^5 + \ldots) x$$

$$+ (y + 4y^2 + 9y^3 + 16y^4 + 25y^5 + \ldots) x^2$$

$$+ (y + 9y^2 + 36y^3 + 100y^4 + 225y^5 + \ldots) x^3$$

$$+ (y + 16y^2 + 100y^3 + 400y^4 + 1225y^5 + \ldots) x^4 + \ldots \quad (10)$$

An explicit formula of $H_m(y)$ is given by Bousquet-Mélou (1992). These functions satisfy the reciprocity relations

$$H_m(1/y) = -y^{m-2} H_m(y) \quad (11)$$

$$G(x,y) + y^2 G(x/y, 1/y) = 0 \quad (12)$$

(Bousquet-Mélou *et al.* 1999).

The anisotropic area and horizontal perimeter generating function $G(x,q)$ and partial generating functions $H_m(q)$, connected by

$$G(x,q) = \sum_{m \geq 1} H_m(q) x^m,$$

satisfy the self-reciprocity and inversion relations

$$H_m(1/q) = -\frac{1}{q} H_m(q)$$

and

$$G(x,q) + qG(x, 1/q) = 0$$

(Bousquet-Mélou *et al.* 1999).

Directed Graph

A GRAPH in which each EDGE is replaced by a directed EDGE, also called a digraph or reflexive graph. A COMPLETE directed graph is called a TOURNAMENT. A directed graph having no symmetric pair of directed edges is called an ORIENTED GRAPH.

If G is an undirected connected GRAPH, then one can always direct the circuit EDGES of G and leave the SEPARATING EDGES undirected so that there is a directed path from any node to another. Such a GRAPH is said to be transitive if the adjacency relation is transitive.

The number of directed graphs of n nodes for $n = 1, 2,$ ... are 1, 3, 16, 218, 9608, ... (Sloane's A000273).

Directed Set

A set S together with a relation $\geq$ which is both transitive and reflexive such that for any two elements $a, b \in S$, there exists another element $c \in S$ with $a \geq c \geq b$. In this case, the relation $\geq$ is said to "direct" the set.

See also Net

Direction Cosine

Let a be the angle between $\mathbf{v}$ and $\mathbf{x}$, b the angle between $\mathbf{v}$ and $\mathbf{y}$, and c the angle between $\mathbf{v}$ and $\mathbf{z}$. Then the direction cosines are equivalent to the (x, y, z) coordinates of a unit vector $\hat{\mathbf{v}}$,

$$\alpha \equiv \cos a \equiv \frac{\mathbf{v} \cdot \hat{\mathbf{x}}}{|\mathbf{v}|} \tag{1}$$

$$\beta \equiv \cos b \equiv \frac{\mathbf{v} \cdot \hat{\mathbf{y}}}{|\mathbf{v}|} \tag{2}$$

$$\gamma \equiv \cos c \equiv \frac{\mathbf{v} \cdot \hat{\mathbf{z}}}{|\mathbf{v}|}. \tag{3}$$

From these definitions, it follows that

$$\alpha^2 + \beta^2 + \gamma^2 = 1. \tag{4}$$

To find the Jacobian when performing integrals over direction cosines, use

$$\theta = \sin^{-1}\left(\sqrt{\alpha^2 + \beta^2}\right) \tag{5}$$

$$\phi = \tan^{-1}\left(\frac{\beta}{\alpha}\right) \tag{6}$$

$$\gamma = \sqrt{1 - \alpha^2 - \beta^2}. \tag{7}$$

The Jacobian is

$$\left|\frac{\partial(\theta, \phi)}{\partial(\alpha, \beta)}\right| = \begin{vmatrix} \frac{\partial \theta}{\partial \alpha} & \frac{\partial \theta}{\partial \beta} \\ \frac{\partial \phi}{\partial \alpha} & \frac{\partial \phi}{\partial \beta} \end{vmatrix}. \tag{8}$$

Using

$$\frac{d}{dx}\left(\sin^{-1} x\right) = \frac{1}{\sqrt{1 - x^2}} \tag{9}$$

$$\frac{d}{dx}\left(\tan^{-1} x\right) = \frac{1}{1 + x^2}, \tag{10}$$

$$\left|\frac{\partial(\theta, \phi)}{\partial(\alpha, \beta)}\right| = \begin{vmatrix} \frac{\frac{1}{2}\left(\alpha^2 + \beta^2\right)^{-1/2} 2\alpha}{\sqrt{1 - \alpha^2 - \beta^2}} & \frac{\frac{1}{2}\left(\alpha^2 + \beta^2\right)^{-1/2} 2\beta}{\sqrt{1 - \alpha^2 - \beta^2}} \\ \frac{-\alpha^{-2}\beta}{1 + \frac{\beta^2}{\alpha^2}} & \frac{\alpha^{-1}}{1 + \frac{\beta^2}{\alpha^2}} \end{vmatrix}$$

$$= \frac{1}{\sqrt{1 - \alpha^2 - \beta^2}} \frac{\left(\alpha^2 + \beta^2\right)^{-1/2}}{1 + \frac{\beta^2}{\alpha^2}} \left(1 + \frac{\beta^2}{\alpha^2}\right)$$

$$= \frac{1}{\sqrt{\left(\alpha^2 + \beta^2\right)\left(1 - \alpha^2 - \beta^2\right)}}, \tag{11}$$

so

$$d\Omega = \sin\theta \, d\phi \, d\theta = \sqrt{\alpha^2 + \beta^2} \left|\frac{\partial(\theta, \phi)}{\partial(\alpha, \beta)}\right| d\alpha \, d\beta$$

$$= \frac{d\alpha \, d\beta}{\sqrt{1 - \alpha^2 - \beta^2}} = \frac{d\alpha \, d\beta}{\gamma}. \tag{12}$$

Direction cosines can also be defined between two sets of Cartesian coordinates,

$$\alpha_1 \equiv \hat{\mathbf{x}}' \cdot \hat{\mathbf{x}} \quad (13)$$

$$\alpha_2 \equiv \hat{\mathbf{x}}' \cdot \hat{\mathbf{y}} \quad (14)$$

$$\alpha_3 \equiv \hat{\mathbf{x}}' \cdot \hat{\mathbf{z}} \quad (15)$$

$$\beta_1 \equiv \hat{\mathbf{y}}' \cdot \hat{\mathbf{x}} \quad (16)$$

$$\beta_2 \equiv \hat{\mathbf{y}}' \cdot \hat{\mathbf{y}} \quad (17)$$

$$\beta_3 \equiv \hat{\mathbf{y}}' \cdot \hat{\mathbf{z}} \quad (18)$$

$$\gamma_1 \equiv \hat{\mathbf{z}}' \cdot \hat{\mathbf{x}} \quad (19)$$

$$\gamma_2 \equiv \hat{\mathbf{z}}' \cdot \hat{\mathbf{y}} \quad (20)$$

$$\gamma_3 \equiv \hat{\mathbf{z}}' \cdot \hat{\mathbf{z}}. \quad (21)$$

Projections of the unprimed coordinates onto the primed coordinates yield

$$\hat{\mathbf{x}}' = (\hat{\mathbf{x}}' \cdot \hat{\mathbf{x}})\hat{\mathbf{x}} + (\hat{\mathbf{x}}' \cdot \hat{\mathbf{y}})\hat{\mathbf{y}} + (\hat{\mathbf{x}}' \cdot \hat{\mathbf{z}})\hat{\mathbf{z}} = \alpha_1 \hat{\mathbf{x}} + \alpha_2 \hat{\mathbf{y}} + \alpha_3 \hat{\mathbf{z}} \quad (22)$$

$$\hat{\mathbf{y}}' = (\hat{\mathbf{y}}' \cdot \hat{\mathbf{x}})\hat{\mathbf{x}} + (\hat{\mathbf{y}}' \cdot \hat{\mathbf{y}})\hat{\mathbf{y}} + (\hat{\mathbf{y}}' \cdot \hat{\mathbf{z}})\hat{\mathbf{z}} = \beta_1 \hat{\mathbf{x}} + \beta_2 \hat{\mathbf{y}} + \beta_3 \hat{\mathbf{z}} \quad (23)$$

$$\hat{\mathbf{z}}' = (\hat{\mathbf{z}}' \cdot \hat{\mathbf{x}})\hat{\mathbf{x}} + (\hat{\mathbf{z}}' \cdot \hat{\mathbf{y}})\hat{\mathbf{y}} + (\hat{\mathbf{z}}' \cdot \hat{\mathbf{z}})\hat{\mathbf{z}} = \gamma_1 \hat{\mathbf{x}} + \gamma_2 \hat{\mathbf{y}} + \gamma_3 \hat{\mathbf{z}}, \quad (24)$$

and

$$x' = \mathbf{r} \cdot \hat{\mathbf{x}}' = \alpha_1 x + \alpha_2 y + \alpha_3 z \quad (25)$$

$$y' = \mathbf{r} \cdot \hat{\mathbf{y}}' = \beta_1 x + \beta_2 y + \beta_3 z \quad (26)$$

$$z' = \mathbf{r} \cdot \hat{\mathbf{z}}' = \gamma_1 x + \gamma_2 y + \gamma_3 z. \quad (27)$$

Projections of the primed coordinates onto the unprimed coordinates yield

$$\hat{\mathbf{x}} = (\hat{\mathbf{x}} \cdot \hat{\mathbf{x}}')\hat{\mathbf{x}}' + (\hat{\mathbf{x}} \cdot \hat{\mathbf{y}}')\hat{\mathbf{y}}' + (\hat{\mathbf{x}} \cdot \hat{\mathbf{z}}')\hat{\mathbf{z}}'$$
$$= \boldsymbol{\alpha}_1 \hat{\mathbf{x}}' + \boldsymbol{\beta}_1 \hat{\mathbf{y}}' + \gamma_1 \hat{\mathbf{z}}' \quad (28)$$

$$\hat{\mathbf{y}} = (\hat{\mathbf{y}} \cdot \hat{\mathbf{x}}')\hat{\mathbf{x}}' + (\hat{\mathbf{y}} \cdot \hat{\mathbf{y}}')\hat{\mathbf{y}}' + (\hat{\mathbf{y}} \cdot \hat{\mathbf{z}}')\hat{\mathbf{z}}'$$
$$= \alpha_2 \hat{\mathbf{x}}' + \beta_2 \hat{\mathbf{y}}' + \gamma_2 \hat{\mathbf{z}}' \quad (29)$$

$$\hat{\mathbf{z}} = (\hat{\mathbf{z}} \cdot \hat{\mathbf{x}}')\hat{\mathbf{x}}' + (\hat{\mathbf{z}} \cdot \hat{\mathbf{x}}')\hat{\mathbf{y}}' + (\hat{\mathbf{z}} \cdot \hat{\mathbf{z}}')\hat{\mathbf{z}}'$$
$$= \alpha_3 \hat{\mathbf{x}}' + \beta_3 \hat{\mathbf{y}}' + \gamma_3 \hat{\mathbf{z}}', \quad (30)$$

and

$$x = \mathbf{r} \cdot \hat{\mathbf{x}} = \alpha_1 x + \beta_1 y + \gamma_1 z \quad (31)$$

$$y = \mathbf{r} \cdot \hat{\mathbf{y}} = \alpha_2 x + \beta_2 y + \gamma_2 z \quad (32)$$

$$z = \mathbf{r} \cdot \hat{\mathbf{z}} = \alpha_3 x + \beta_3 y + \gamma_3 z. \quad (33)$$

Using the orthogonality of the coordinate system, it must be true that

$$\hat{\mathbf{x}} \cdot \hat{\mathbf{y}} = \hat{\mathbf{y}} \cdot \hat{\mathbf{z}} = \hat{\mathbf{z}} \cdot \hat{\mathbf{x}} = 0 \quad (34)$$

$$\hat{\mathbf{x}} \cdot \hat{\mathbf{x}} = \hat{\mathbf{y}} \cdot \hat{\mathbf{y}} = \hat{\mathbf{z}} \cdot \hat{\mathbf{z}} = 1, \quad (35)$$

giving the identities

$$\alpha_l \alpha_m + \beta_l \beta_m + \gamma_l \gamma_m = 0 \quad (36)$$

for $l, m = 1, 2, 3$ and $l \neq m$, and

$$\alpha_l^2 + \beta_l^2 + \gamma_l^2 = 1 \quad (37)$$

for $l = 1, 2, 3$.. These two identities may be combined into the single identity

$$\alpha_l \alpha_m + \beta_l \beta_m + \gamma_l \gamma_m = \delta_{lm}, \quad (38)$$

where δ_{lm} is the KRONECKER DELTA.

Direction Vector

UNIT VECTOR

Directional Derivative

$$\nabla_{\mathrm{u}} f \equiv \nabla f \cdot \frac{\mathbf{u}}{|\mathbf{u}|} \propto \lim_{h \to 0} \frac{f(\mathrm{x} + h\mathbf{u}) - f(\mathrm{x})}{h}. \quad (1)$$

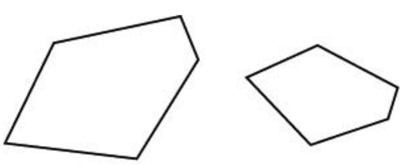
$\nabla_{\mathrm{u}} f(x_0, y_0, z_0)$ is the rate at which the function $w = f(x, y, z)$ changes at (x_0, y_0, z_0) in the direction $\mathbf{u}$. Let $\mathbf{u}$ be a UNIT VECTOR in CARTESIAN COORDINATES, so

$$|\mathbf{u}| = \sqrt{u_x^2 + u_y^2 + u_z^2} = 1, \quad (2)$$

then

$$\nabla_{\mathrm{u}} f = \frac{\partial f}{\partial x} u_x + \frac{\partial f}{\partial y} u_y + \frac{\partial f}{\partial z} u_z. \quad (3)$$

The directional derivative is often written in the notation



$$\frac{d}{ds} \equiv \hat{s} \cdot \nabla = s_x \frac{\partial}{\partial x} + s_y \frac{\partial}{\partial y} + s_z \frac{\partial}{\partial z}. \quad (4)$$

Directly Proportional

Two quantities y and x are said to be directly proportional, proportional, or "in direct proportion" if y is given by a constant multiple of x, i.e., $y = cx$ for c a constant. This relationship is commonly written $y \propto x$..

See also INVERSELY PROPORTIONAL, PROPORTIONAL

Directly Similar

directly similar

Two figures are said to be SIMILAR when all corresponding ANGLES are equal, and are directly similar

when all corresponding ANGLES are equal and described in the same rotational sense.

Any two directly similar figures are related either by a TRANSLATION or by a SPIRAL SIMILARITY (Coxeter and Greitzer 1967, p. 97).

Director

A PLANE parallel to two (or more) SKEW LINES, also called a director plane. The orientation of a director is fixed, but it is specified uniquely only if a point lying on it is also specified.

A director of two SKEW LINES is perpendicular to the line of shortest distance of these two lines (Altshiller-Court 1979, p. 1).

Directrix

DIRECTRIX (CONIC SECTION), DIRECTRIX (GRAPH), DIRECTRIX (RULED SURFACE)

Directrix (Conic Section)

The LINE which, together with the point known as the FOCUS, serves to define a CONIC SECTION as the LOCUS of points whose distance from the FOCUS is proportional to the horizontal distance from the directrix. If the ratio $r = 1$, the conic is a PARABOLA, if $r < 1$, it is an ELLIPSE, and if $r > 1$, it is a HYPERBOLA (Hilbert and Cohn-Vossen 1999, p. 27).

HYPERBOLAS and noncircular ELLIPSES have two distinct FOCI and two associated DIRECTRICES, each DIRECTRIX being PERPENDICULAR to the line joining the two foci (Eves 1965, p. 275).

Dirichlet Beta Function

$$\beta(x) \equiv \sum_{n=0}^{\infty} (-1)^n (2n+1)^{-x} \tag{1}$$

$$\beta(x) = 2^{-x} \Phi\left(-1, x, \frac{1}{2}\right), \tag{2}$$

where $\Phi(z, s, a)$ is the LERCH TRANSCENDENT. The beta function can be written in terms of the HURWITZ ZETA FUNCTION $\zeta(x, a)$ by

$$\beta(x) = \frac{1}{4^x}\left[\zeta\left(x, \frac{1}{4}\right) - \zeta\left(x, \frac{3}{4}\right)\right]. \tag{3}$$

The beta function can be evaluated directly for POSITIVE ODD x as

$$\beta(2k+1) = \frac{(-1)^k E_{2k}}{2(2k)!}\left(\frac{1}{2}\pi\right)^{2k+1}, \tag{4}$$

where E_n is an EULER NUMBER. The beta function can be defined over the whole COMPLEX PLANE using ANALYTIC CONTINUATION,

$$\beta(1-z) = \left(\frac{2}{\pi}\right)^z \sin\left(\frac{1}{2}\pi z\right) \Gamma(z) \beta(z), \tag{5}$$

where $\Gamma(z)$ is the GAMMA FUNCTION.
Particular values for β are

$$\beta(1) = \frac{1}{4}\pi \tag{6}$$

$$\beta(2) \equiv K \tag{7}$$

$$\beta(3) = \frac{1}{32}\pi^3, \tag{8}$$

where K is CATALAN'S CONSTANT.

Dirichlet Divisor Problem

Let the DIVISOR FUNCTION $d(n) = \nu(n) = \sigma_0(n)$ be the number of DIVISORS of n (including n itself). For a PRIME p, $\nu(p) = 2$. In general,

$$\sum_{k=1}^{n} \nu(k) = n \ln n + (2\gamma - 1)n + \mathcal{O}\left(n^{\theta}\right),$$

where γ is the EULER-MASCHERONI CONSTANT. Dirichlet originally gave $\theta \approx 1/2$ (Hardy 1999, pp. 67–8), and Landau (1916) showed than $\theta \geq 1/4$ (Hardy 1999, p. 81). The following table summarizes incremental progress on the upper limit (Hardy 1999, p. 81).

θ	approx.	citation
7/22	0.31818	1988
27/82	0.32927	van der Corput 1928
33/100	0.33000	van der Corput 1922
1/3	0.33333	Voronoi 1903
1/2	0.50000	Dirichlet

Dirichlet Energy

Let h be a real-valued HARMONIC FUNCTION on a bounded DOMAIN Ω, then the Dirichlet energy is defined as $\int_{\Omega} |\nabla h|^2 dx$, where ∇ is the GRADIENT.

See also ENERGY

Dirichlet Eta Function

The function defined by

$$\eta(x) \equiv \sum_{n=1}^{\infty} (-1)^{n-1} n^{-x} = \left(1 - 2^{1-x}\right)\zeta(x), \tag{1}$$

where $n = 1, 2, \ldots$, and $\zeta(x)$ is the RIEMANN ZETA FUNCTION. Note that Borwein and Borwein (1986, p. 289) use the notation $\alpha(s)$ instead of $\eta(s)$.. Particular values are given in Abramowitz and Stegun (1972, p. 811).
The eta function is related to the RIEMANN ZETA FUNCTION and DIRICHLET LAMBDA FUNCTION by

$$\frac{\zeta(\nu)}{2^{\nu}} = \frac{\lambda(\nu)}{2^{\nu} - 1} = \frac{\eta(\nu)}{2^{\nu} - 2} \tag{2}$$

and

$$\zeta(\nu) + \eta(\nu) = 2\lambda(\nu) \tag{3}$$

(Spanier and Oldham 1987). The eta function is also a special case of the POLYLOGARITHM function,

$$\eta(x) = -Li_x(-1). \tag{4}$$

The value $\eta(1)$ may be computed by noting that the MACLAURIN SERIES for $\ln(1+x)$ for $-1 \leq x \leq 1$ is

$$\ln(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \cdots \tag{5}$$

Therefore,

$$\ln 2 = \ln(1+1) = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots$$

$$= \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} = \eta(1). \quad (6)$$

The derivative of the eta function is given by

$$\eta'(x) = -2^{1-x} \ln 2\zeta(x) + (1-2^{1-x})\zeta'(x), \quad (7)$$

or in the special case $x = 0$, by

$$\lim_{x\to 0}\left[\frac{d}{dx}\eta(x)\right] = -\ln 2 - \zeta'(0) = -\ln 2 + \frac{1}{2}\ln(2\pi)$$

$$= -\ln\left(\sqrt{\frac{2}{\pi}}\right) = \frac{1}{2}\ln\left(\frac{1}{2}\pi\right). \quad (8)$$

This latter fact provides a remarkable proof of the WALLIS FORMULA.

Values for EVEN INTEGERS are related to the analytical values of the RIEMANN ZETA FUNCTION. $\eta(0)$ is defined to be $\frac{1}{2}$.

$$\eta(0) = \frac{1}{2}$$

$$\eta(1) = \ln 2$$

$$\eta(2) = \frac{\pi^2}{12}$$

$$\eta(3) = 0.90154\ldots$$

$$\eta(4) = \frac{7\pi^4}{720}.$$

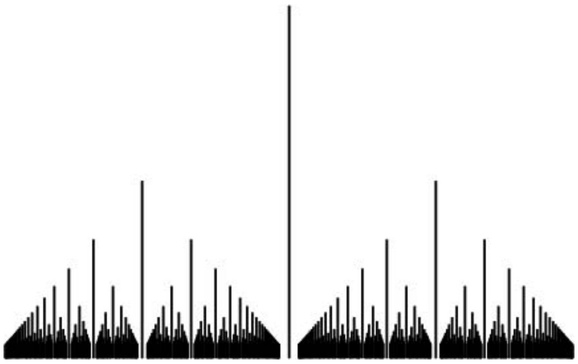
Dirichlet Fourier Series Conditions

A piecewise regular function which

1. Has a finite number of finite discontinuities and
2. Has a finite number of extrema

can be expanded in a FOURIER SERIES which converges to the function at continuous points and the mean of the POSITIVE and NEGATIVE limits at points of discontinuity.

See also FOURIER SERIES



Dirichlet Function

Let c and $d \neq c$ be REAL NUMBERS (usually taken as $c = 1$ and $d = 0$). The Dirichlet function is defined by

$$D(x) = \begin{cases} c & \text{for } x \text{ rational} \\ d & \text{for } x \text{ irrational} \end{cases} \quad (1)$$

and is discontinuous everywhere. The Dirichlet function can be written analytically as

$$D(x) = \lim_{m\to\infty} \lim_{n\to\infty} \cos^{2n}(m!\pi x). \quad (2)$$

Because the Dirichlet function cannot be plotted without producing a solid blend of lines, a modified version can be defined as

$$D_M(x) = \begin{cases} 0 & \text{for } x \text{ irrational} \\ 1/b & \text{for } x = a/b \text{ a reduced fraction} \end{cases} \quad (3)$$

(Dixon 1991), illustrated above. This function is continuous at irrational x and discontinuous at rational x (although a small interval around an irrational point x contains infinitely many ration points, these rationals will have very large denominators). When viewed from a corner along the line $y = x$ in normal perspective, a QUADRANT of EUCLID'S ORCHARD turns into the modified Dirichlet function (Gosper).

Dirichlet Integrals

There are several types of integrals which go under the name of a "Dirichlet integral." The integral

$$D[u] = \int_\Omega |\nabla u|^2 dV \tag{1}$$

appears in DIRICHLET'S PRINCIPLE.

The integral

$$\frac{1}{2\pi}\int_{-\pi}^{\pi} f(x)\frac{\sin\left[\left(n+\frac{1}{2}\right)x\right]}{\sin\left(\frac{1}{2}x\right)}dx, \tag{2}$$

where the kernel is the DIRICHLET KERNEL, gives the nth partial sum of the FOURIER SERIES.

Another integral is denoted

$$\delta_k \equiv \frac{1}{\pi}\int_{-\infty}^{\infty}\frac{\sin\alpha_k\rho_k}{\rho_k}e^{i\rho_k\gamma_k}d\rho_k = \begin{cases} 0 & \text{for } |\gamma_k| > \alpha_k \\ 1 & \text{for } |\gamma_k| < \alpha_k \end{cases} \tag{3}$$

for $k = 1, ..., n$.

There are two types of Dirichlet integrals which are denoted using the letters C, D, I, and J. The type 1 Dirichlet integrals are denoted I, J, and IJ, and the type 2 Dirichlet integrals are denoted C, D, and CD.

The type 1 integrals are given by

$$\mathrm{I} \equiv \int\int\ldots\int f(t_1+t_2+...+t_n)t_1^{\alpha_1-1}t_2^{\alpha_2-1}\ldots t_n^{\alpha_n-1}dt_1dt_2dt_n$$

$$= \frac{\Gamma(\alpha_1)\Gamma(\alpha_2)...\Gamma(\alpha_n)}{\Gamma(\sum_n\alpha_n)}\int_0^1 f(r)r\left(\sum_n\alpha\right)^{-1}dr, \tag{4}$$

where $\Gamma(z)$ is the GAMMA FUNCTION. In the case $n = 2$,

$$\mathrm{I} = \int\int_T x^p y^q dxdy = \frac{p!q!}{(p+q+2)!} = \frac{B(p+1,q+1)}{p+q+2}, \tag{5}$$

where the integration is over the TRIANGLE T bounded by the X-AXIS, Y-AXIS, and line $x+y=1$ and $B(x,y)$ is the BETA FUNCTION.

The type 2 integrals are given for b-D vectors $\mathbf{a}$ and $\mathbf{r}$, and $0 \le c \le b$,

$$C_{\mathbf{a}}^{(b)}(\mathbf{r},m) = \frac{\Gamma(m+R)}{\Gamma(m)\prod_{i=1}^b\Gamma(r_i)}\int_0^{a_1}\cdots\int_0^{a_b} \times \frac{\prod_{i=1}^b x_i^{r_{i-1}}dx_i}{\left(1+\sum_{i=1}^b x_i\right)^{m+R}} \tag{6}$$

$$D_{\mathbf{a}}^{(b)}(\mathbf{r},m) = \frac{\Gamma(m+R)}{\Gamma(m)\prod_{i=1}^b\Gamma(r_i)}\int_{a1}^{\infty}\cdots\int_{ak}^{\infty} \times \frac{\prod_{i=1}^b x_i^{r_{i-1}}dx_i}{\left(1+\sum_{i=1}^b xi\right)^{m+R}} \tag{7}$$

$$CD_{\mathbf{a}}^{(c,d-c)}(\mathbf{r},m) = \frac{\Gamma(m+R)}{\Gamma(m)\prod_{i=1}^b\Gamma(r_i)}\int_0^{a_c}\int_{a_{c+1}}^{\infty}\int_{ab}^{\infty}\frac{\prod_{i=1}^b x_i^{r_{i-1}}dx_i}{\left(1+\sum_{i=1}^b x_i\right)^{m+R}}, \tag{8}$$

where

$$R \equiv \sum_{i=1}^k r_i \tag{9}$$

$$a_i \equiv \frac{p_i}{1-\sum_{i=1}^k p_i}, \tag{10}$$

and p_i are the cell probabilities. For equal probabilities, $a_i = 1$. The Dirichlet D integral can be expanded as a MULTINOMIAL SERIES as

$$D_{\mathbf{a}}^{(b)}(\mathbf{r},m) = \frac{1}{\left(1+\sum_{i=1}^b\right)^m} \times \sum_{x_1<r_1}\cdots\sum_{x_b<r_b}\binom{m-1+\sum_{a=1}^b x_i}{m-1, x_1\ldots, x_b}$$

$$\prod_{i=1}^{} b\left(\frac{a_i}{1+\sum_{k=1}^b ak}\right)^{x_i}. \tag{11}$$

For small b, C and D can be expressed analytically either partially or fully for general arguments and $a_i = 1$.

$$C_1^{(1)}(r_2;r_1) = \frac{\Gamma(r_1+r_2)\,{}_2F_i(r_2,r_1+r_2;1+r_2;-1)}{r_2\Gamma(r_1)\Gamma(r_2)} \tag{12}$$

$$C_1^{(2)}(r_2,r_3;r_1) = \frac{\Gamma(r_1+r_2+r_3)}{r_2\Gamma(r_1)\Gamma(r_2)\Gamma(r_3)} \times \int_0^1 {}_2F_1 y^{r_a-1}(1+y)^{-(r_1+r_2+r_3)}dy, \tag{13}$$

where

$${}_2F_1 \equiv_2 F_1\left(r_2, r_1+r_2+r_3; 1+r_2, -(1+y)^{-1}\right) \tag{14}$$

is a HYPERGEOMETRIC FUNCTION.

$$D_1^{(1)}(r_2;r_1) = \frac{\Gamma(r_1+r_2)\,{}_2F_1(r_1,r_1++r_2;1+r_1;-1)}{r_1\Gamma(r_1)\Gamma(r_2)} \tag{15}$$

$$D_1^{(2)}(r_2, r_3; r_1) = \frac{\Gamma(r_1 + r_2 + r_3)}{(r_1 + r_3)\Gamma(r_1)\Gamma(r_2)\Gamma(r_3)} \int_1^\infty {}_2F_1 y^{r_3 - 1} dy, \qquad (16)$$

where

$${}_2F_1 \equiv {}_2F_1(r_1 + r_3, r_1 + r_2 + r_3; 1 + r_1 + r_3; -1 - y). \qquad (17)$$

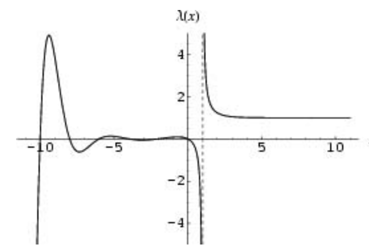
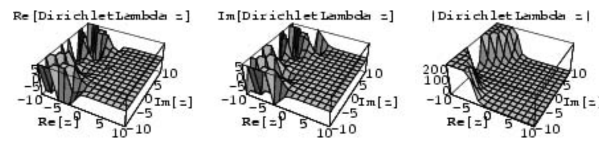
Dirichlet Kernel

The Dirichlet kernel D_n^M is obtained by integrating the CHARACTER $e^{i(\xi, x)}$ over the BALL $|\xi| \leq M$,

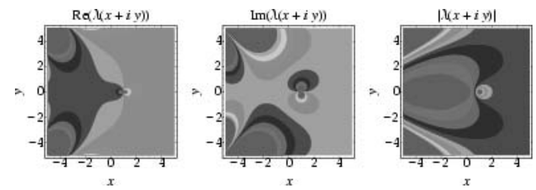
$$D_n^M = -\frac{1}{2\pi r} \frac{d}{dr} D_{n-2}^M.$$



The Dirichlet kernel of a DELTA SEQUENCE is given by



$$\delta_n(x) \equiv \frac{1}{2\pi} \frac{\sin\left[\left(n + \frac{1}{2}\right)x\right]}{\sin\left(\frac{1}{2}x\right)}.$$



The integral of this kernel is called the DIRICHLET INTEGRAL $D[u]$.

See also DELTA SEQUENCE, DIRICHLET INTEGRALS, DIRICHLET'S LEMMA

Dirichlet Lambda Function

$$\lambda(x) \equiv \sum_{n=0}^{\infty} (2n = 1)^{-x} = (1 - 2^{-x})\zeta(x) \qquad (1)$$

for $x = 2, 3, \ldots$, where $\zeta(x)$ is the RIEMANN ZETA FUNCTION. The function is undefined at $x = 1$. It can be computed in closed form where $\zeta(x)$ can, that is for EVEN POSITIVE n. It is related to the RIEMANN ZETA FUNCTION and DIRICHLET ETA FUNCTION by

$$\frac{\zeta(\nu)}{2^\nu} = \frac{\lambda(\nu)}{2^\nu - 1} = \frac{\eta(\nu)}{2^\nu - 2} \qquad (2)$$

and

$$\zeta(\nu) + \eta(\nu) = 2\lambda(\nu) \qquad (3)$$

(Spanier and Oldham 1987). Special values of $\lambda(n)$ include

$$\lambda(2) = \frac{\pi^2}{8} \qquad (4)$$

$$\lambda(4) = \frac{\pi^4}{96}. \qquad (5)$$

Dirichlet L-Series

Series OF THE FORM

$$L_k(s,\chi) \equiv \sum_{n=1}^{\infty} \chi_k(n) n^{-s}, \tag{1}$$

where the CHARACTER $\chi_k(n)$ is an INTEGER FUNCTION with period m, are called Dirichlet L-series. These series are very important in ADDITIVE NUMBER THEORY (they were used, for instance, to prove DIRICHLET'S THEOREM), and have a close connection with MODULAR FORMS. Dirichlet L-series can be written as sums of LERCH TRANSCENDENTS with z a POWER of $e^{2\pi i/m}$.

The DIRICHLET ETA FUNCTION

$$\eta(s) \equiv \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^s} = \left(1-2^{1-s}\right)\zeta(s) \tag{2}$$

(for $s \neq 1$), DIRICHLET BETA FUNCTION

$$L_{-4}(s) = \beta(s) \equiv \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^s}, \tag{3}$$

and RIEMANN ZETA FUNCTION

$$L_{+1}(s) = \zeta(s) \equiv \sum_{n=0}^{\infty} \frac{1}{n^s} \tag{4}$$

are all Dirichlet L-series (Borwein and Borwein 1987, p. 289).

Hecke found a remarkable connection between each MODULAR FORM with FOURIER SERIES

$$f(r) = c(0) + \sum_{n=1}^{\infty} c(n) e^{2\pi i n\tau} \tag{5}$$

and the Dirichlet L-series

$$\phi(s) = \sum_{m=1}^{\infty} \frac{c(n)}{n^s} \tag{6}$$

This Dirichlet series converges absolutely for $\sigma = \Re[s] > k+1$ (if f is a CUSP FORM) and $\sigma > 2k$ if f is not a CUSP FORM. In particular, if the coefficients $c(n)$ satisfy the multiplicative property

$$c(m)c(n) = \sum_{d|(m,n)} d^{2k-1} c\left(\frac{mn}{d^2}\right), \tag{7}$$

then the Dirichlet L-series will have a representation OF THE FORM

$$\phi(s) = \prod_p \frac{1}{1 - c(p)p^{-s} + p^{2k-1}p^{-2s}}, \tag{8}$$

which is absolutely convergent with the Dirichlet series (Apostol 1997, pp. 136–37). In addition, let $k \geq 4$ be an EVEN integer, then $\phi(s)$ can be ANALYTICALLY CONTINUED beyond the line $\sigma = k$ such that

1. If $c(0) = 0$, then $\phi(s)$ is an ENTIRE FUNCTION of s,
2. If $c(0) \neq 0$, $\phi(s)$ is analytic for all s except a single SIMPLE POLE at $s = k$ with RESIDUE

$$\frac{(-1)^{k/2} c(0)(2\pi)^k}{\Gamma(k)}, \tag{9}$$

where $\Gamma(k)$ is the GAMMA FUNCTION, and
3. $\phi(s)$ satisfies

$$(2\pi)^{-s}\Gamma(s)\phi(s) = (-1)^{k\cdot 2}(2\pi)^{s-k}\Gamma(k-s)\phi(k-s) \tag{10}$$

(Apostol 1997, p. 137).

The CHARACTER χ_k is called primitive if the CONDUCTOR $f(x) = k$. Otherwise, χ_k is imprimitive. A primitive L-series modulo k is then defined as one for which $\chi_k(n)$ is primitive. All imprimitive L-series can be expressed in terms of primitive L-series.

Let $P = 1$ or $P = \prod_{i=1}^{t} p_i$, where p_i are distinct ODD PRIMES. Then there are three possible types of primitive L-series with REAL COEFFICIENTS. The requirement of REAL COEFFICIENTS restricts the CHARACTER to $\chi_k(n) = \pm 1$ for all k and n. The three type are then

1. If $k = P$ (e.g., $k = 1, 3, 5, \ldots$) or $k = 4P$ (e.g., $k = 4, 12, 20, \ldots$), there is exactly one primitive L-series.
2. If $k = 8P$ (e.g., $k = 8, 24, \ldots$), there are two primitive L-series.
3. If $k = 2P, Pp_i$, or $2^\alpha P$ where $\alpha > 3$ (e.g., $k = 2, 6, 9, \ldots$), there are no primitive L-series

(Zucker and Robertson 1976). All primitive L-series are ALGEBRAICALLY INDEPENDENT and divide into two types according to

$$\chi_k(k-1) = \pm 1. \tag{11}$$

Primitive L-series of these types are denoted $L\pm$. For a primitive L-series with REAL CHARACTER (NUMBER THEORY), if $k = P$, then

$$L_k = \begin{cases} L_{-k} & \text{if} \quad P \equiv 3 \pmod 4 \\ L_k & \text{if} \quad P \equiv 1 \pmod 4 \end{cases}. \tag{12}$$

If $k = 4P$, then

$$L_k = \begin{cases} L_{-k} & \text{if} \quad P \equiv 1 \pmod 4 \\ L_k & \text{if} \quad P \equiv 3 \pmod 4 \end{cases}, \tag{13}$$

and if $k = 8P$, then there is a primitive function of each type (Zucker and Robertson 1976).

The first few primitive NEGATIVE L-series are L_{-3}, L_{-4}, L_{-7}, L_{-8}, L_{11}, L_{-15}, L_{-19}, L_{-20}, L_{-23}, L_{-24}, L_{-31},

L_{-35}, L_{-39}, L_{-40}, L_{-43}, L_{-47}, L_{-51}, L_{-52}, L_{-55}, L_{-56}, L_{-59}, L_{-67}, L_{-68}, L_{-71}, L_{-79}, L_{-83}, L_{-84}, L_{-87}, L_{-88}, L_{-91}, L_{-95}, ... (Sloane's A003657), corresponding to the negated discriminants of IMAGINARY QUADRATIC FIELDS. The first few primitive POSITIVE L-series are $L_{+1}, L_{+5}, L_{+8}, L_{+12}, L_{+13}, L_{+17}, L_{+21}, L_{+24}, L_{+28}, L_{+29}$, L_{+33}, L_{+37}, L_{+40}, L_{+41}, L_{+44}, L_{+53}, L_{+56}, L_{+57}, L_{+60}, L_{+61}, L_{+65}, L_{+69}, L_{+73}, L_{+76}, L_{+77}, L_{+85}, L_{+88}, L_{+89}, L_{+92}, L_{+93}, L_{+97}, ... (Sloane's A046113).

The KRONECKER SYMBOL is a REAL CHARACTER modulo k, and is in fact essentially the only type of REAL primitive CHARACTER (Ayoub 1963). Therefore,

$$L_{+d}(s) = \sum_{n=1}^{\infty} (d|n) n^{-s} \tag{14}$$

$$L_{-d}(s) = \sum_{n=1}^{\infty} (-d|n) n^{-s}, \tag{15}$$

where $(d|n)$ is the KRONECKER SYMBOL (Borwein and Borwein 1986, p. 293). The functional equations for $L_{\pm}$ are

$$L_{-k}(s) = 2^s \pi^{s-1} k^{-s+1/2} \Gamma(1-s) \cos\left(\frac{1}{2} s\pi\right) L-k(1-s) \tag{16}$$

$$L_{+k}(s) = 2^s \pi^{s-1} k^{-s+1/2} \Gamma(1-s) \sin\left(\frac{1}{2} s\pi\right) L_{+k}(1-s) \tag{17}$$

For m a POSITIVE INTEGER

$$L_{+k}(-2m) = 0 \tag{18}$$

$$L_{-k}(1-2m) = 0 \tag{19}$$

$$L_{+k}(2m) = R k^{-1/2} \pi^{2m} \tag{20}$$

$$L_{-k}(2m-1) = R' k^{-1/2} \pi^{2m-1} \tag{21}$$

$$L_{+k}(1-2m) = \frac{(-1)^m (2m-1)! R}{(2k)^{2m-1}} \tag{22}$$

$$L_{-k}(-2k) = \frac{(-1)^m R' (2m)!}{(2k)^{2m}} \tag{23}$$

where R and R' are RATIONAL NUMBERS. Nothing general appears to be known about $L_{-k}(2m)$ or $L_{+k}(2m-1)$, although it is possible to express all $L_{\pm}(1)$ in terms of known transcendentals (Zucker and Robertson 1976).

$L_{+k}(1)$ can be expressed in terms of transcendentals by

$$L_d(1) = h(d) \kappa(d), \tag{24}$$

where $h(d)$ is the CLASS NUMBER and $\kappa(d)$ is the DIRICHLET STRUCTURE CONSTANT. Some specific values of primitive L-series are

$$L_{-15}(1) = \frac{2\pi}{\sqrt{15}}$$

$$L_{-11}(1) = \frac{\pi}{\sqrt{11}}$$

$$L_{-8}(1) = \frac{\pi}{2\sqrt{2}}$$

$$L_{-7}(1) = \frac{\pi}{\sqrt{7}}$$

$$L_{-4}(1) = \frac{1}{4}\pi$$

$$L_{-3}(1) = \frac{\pi}{3\sqrt{3}}$$

$$L_{+5}(1) = \frac{2}{\sqrt{5}} \ln\left(\frac{1+\sqrt{5}}{2}\right)$$

$$L_{+s}(1) = \frac{\ln(1+\sqrt{2})}{\sqrt{2}}$$

$$L_{+12}(1) = \frac{\ln(2+\sqrt{3})}{\sqrt{3}}$$

$$L_{+13}(1) = \frac{2}{\sqrt{13}} \ln\left(\frac{3+\sqrt{13}}{2}\right)$$

$$L_{+17}(1) = \frac{2}{\sqrt{17}} \ln(4+\sqrt{17})$$

$$L_{+21}(1) = \frac{2}{\sqrt{21}} \ln\left(\frac{5+\sqrt{21}}{2}\right)$$

$$L_{+24}(1) = \frac{\ln(5+2\sqrt{6})}{\sqrt{6}}.$$

In particular,

$$L_{-3}(1) = L(1,\chi) = \sum_{n=0}^{\infty} \frac{1}{(3n+1)(3n+2)} \tag{25}$$

for χ a nontrivial Dirichlet character modulo 3 (Ireland and Rosen 1990, p. 266).

No general forms are known for $L_{-k}(2m)$ and $L_{+k}(2m-1)$ in terms of known transcendentals. For example,

$$L_{-4}(2) = \beta(2) \equiv K, \tag{26}$$

where K is defined as CATALAN'S CONSTANT.

Dirichlet Problem

The problem of finding the connection between a continuous function f on the boundary ∂R of a region R with a HARMONIC FUNCTION taking on the value f on ∂R. In general, the problem asks if such a solution exists and, if so, if it is unique. The Dirichlet problem is extremely important in mathematical physics (Courant and Hilbert 1989, pp. 179–80 and 240; Logan 1997; Krantz 1999b).

If f is a CONTINUOUS FUNCTION on the boundary of the open unit disk $\partial D(0,1)$, then define

$$u(z)=\begin{cases}\dfrac{1}{2\pi}\displaystyle\int_0^{2\pi} f(e^{i\psi})\,\dfrac{1-|z|^2}{|z-e^{i\psi}|^2}\,d\psi & \text{if } z\in D(0,\ 1)\\ f(z) & \text{if } z\in\partial D(0,\ 1)\end{cases},$$

where $\partial D(0,1)$, is the boundary of $D(0,1)$. Then u is continuous on the closed unit disk $\overline{D}(0,1)$ and harmonic on $D(0,1)$ (Krantz 1999a, p. 93).

Dirichlet Region

VORONOI POLYGON

Dirichlet Series

A series

$$\sum a(n)e^{-\lambda(n)z},$$

where $a(n)$ and z are COMPLEX and $\{\lambda(n)\}$ is a MONOTONIC increasing sequence of REAL NUMBERS is called a general Dirichlet series. The numbers $\lambda(n)$ are called the exponents, and $a(n)$ are called the coefficients. When $\lambda(n)=\ln n$, then $e^{-\lambda(n)z}=n^{-z}$, the series is a normal DIRICHLET L-SERIES. The Dirichlet series is a special case of the LAPLACE-STIELTJES TRANSFORM.

VORONOI DIAGRAM

Dirichlet's Approximation Theorem

Given any REAL NUMBER θ and any POSITIVE INTEGER N, there exist integers h and k with $0 \leq k \leq N$ such that

$$|k\theta - h| < \frac{1}{N}.$$

A slightly weaker form of the theorem states that for every real θ, there exist integers h and k with $k > 0$ and $(h, k)1 = 1$ such that

$$\left|\theta - \frac{h}{k}\right| < \frac{1}{k^2}.$$

Dirichlet's Principle

Dirichlet's principle, also known as Thomson's principle, states that here exists a function u that minimizes the functional

$$D[u] = \int_\Omega |\nabla u|^2 dV$$

(called the DIRICHLET INTEGRAL) for $\Omega \subset \mathbb{R}^2$ or $\mathbb{R}^3$ among all the functions $u \in C^{(1)}(\Omega) \cap C^{(0)}(\bar{\Omega})$ which take on given values f on the boundary $\partial\Omega$ of Ω, and that function u satisfies $\nabla^2 = 0$ in Ω, $u|\partial\Omega = f$, $u \in C^{(2)}(\Omega) \cap C^{(0)}(\bar{\Omega})$. Weierstrass showed that Dirichlet's argument contained a subtle fallacy. As a result, it can be claimed only that there exists a lower bound to which $D[u]$ comes arbitrarily close without being forced to actually reach it. Kneser, however, obtained a valid proof of Dirichlet's principle.

Dirichlet's Theorem

Given an ARITHMETIC SERIES of terms $an+b$, for $n=1$, 2, ..., the series contains an infinite number of PRIMES if a and b are RELATIVELY PRIME, i.e., $(a,b)=1$. Dirichlet proved this theorem using DIRICHLET L-SERIES, but the proof is challenging enough that, in their classic text on NUMBER THEORY, the usually explicit Hardy and Wright (1979) report "this theorem is too difficult for insertion in this book."

Disc

DISK

Disconnected Form

A FORM which is the sum of two FORMS involving separate sets of variables.

Disconnected Graph

A graph is said to be disconnected if it is not CONNECTED, i.e., if there exist two nodes is G such that no edge in G having those nodes as endpoints. The numbers of disconnected simple unlabeled graphs on $n=1$, 2, ... nodes are 0, 1, 2, 5, 13, 44, 191, ... (Sloane's A000719).
If G is disconnected, then its complement $\bar{G}$ is connected (Skiena 1990, p. 171; Bollobás 1998). However, the converse is not true, as can be seen using the example of the CYCLE GRAPH C_5 which is connected and isomorphic to its complement.

Disconnectivity

Disconnectivities are mathematical entities which stand in the way of a SPACE being contractible (i.e., shrunk to a point, where the shrinking takes place inside the SPACE itself). When dealing with TOPOLOGICAL SPACES, a disconnectivity is interpreted as a "HOLE" in the space. Disconnectivities in SPACE are studied through the EXTENSION PROBLEM or the LIFTING PROBLEM.

See also EXTENSION PROBLEM, HOLE, LIFTING PROBLEM

Discontinuity

A point at which a mathematical object is DISCONTINUOUS.

Discontinuous

Not CONTINUOUS. A point at which a function is discontinuous is called a DISCONTINUITY, or sometimes a JUMP.

See also CONTINUOUS, DISCONTINUITY

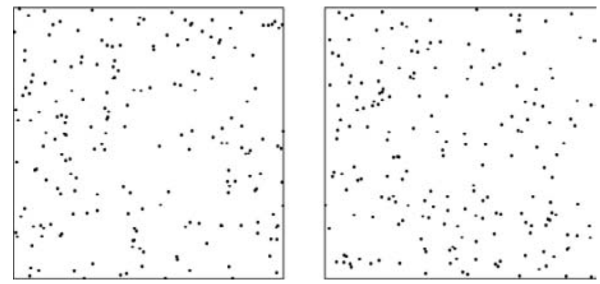
Discordant Permutation

MARRIED COUPLES PROBLEM



Discrepancy Theorem

Let $s_1, s_2, ...$ be an infinite series of real numbers lying between 0 and 1. Then corresponding to any arbitrarily large K, there exists a positive integer n and two subintervals of equal length such that the number of s_v with $v = 1, 2, ..., n$ which lie in one of the subintervals differs from the number of such s_v that lie in the other subinterval by more than K (van der Corput 1935ab, van Aardenne-Ehrenfest 1945, 1949, Roth 1954).

This statement can be refined as follows. Let N be a large integer and $s_1, s_2, ..., s_N$ be a sequence of N real numbers lying between 0 and 1. Then for any integer $1 \leq n \leq N$ and any real number α satisfying $0 < \alpha < 1$, let $D_n(\alpha)$ denote the number of s_v with $v = 1, 2, ..., n$ that satisfy $0 \leq s_v < \alpha$. Then there exist n and α such that

$$|D_n(\alpha) - n\alpha| > c_1 \frac{\ln \ln N}{\ln \ln \ln N}$$

where c_1 is a positive constant.

This result can be further strengthened, which is most easily done by reformulating the problem. Let $N > 1$ be an integer and $P_1, P_2, ..., P_N$ be N (not necessarily distinct) points in the square $0 \leq x \leq 1$, $0 \leq y \leq 1$. Then

$$\int_0^1 \int_0^1 [S(x,y) - Nxy]^2 dx dy > c_2 \ln N,$$

where c_2 is a positive constant and $S(u,v)$ is the number of points in the rectangle $0 \leq x < u$, $0 \leq y < v$ (Roth 1954). Therefore,

$$|S(x,y) - Nxy| > c_3 \sqrt{\ln N},$$

and the original result can be stated as the fact that there exist n and α such that

$$|D_n(\alpha) - n\alpha| > c_4 \sqrt{\ln N}.$$

The randomly distributed points shown in the above squares have $|S(x,y) - Nxy|^2 = 6.40$ and 9.11, respectively.

Similarly, the discrepancy of a set of N points in a unit d-HYPERCUBE satisfies

$$|S(x,y) - Nxy| > c(\ln N)^{(d-1)/2}$$

(Roth 1954, 1976, 1979, 1980).

Discrete Fourier Transform

The FOURIER TRANSFORM is defined as

$$f(\nu)=\mathscr{F}[f(t)]=\int_{-\infty}^{\infty} f(t)e^{-2\pi i\nu t}\,dt. \qquad (1)$$

Now consider generalization to the case of a discrete function, $f(t)\to f(t_k)$ by letting $f_k\equiv f(t_k)$, where $t_k\equiv k\Delta$, with $k=0, ..., N-1$. Choose the frequency step such that

$$\nu_n=\frac{n}{N\Delta}, \qquad (2)$$

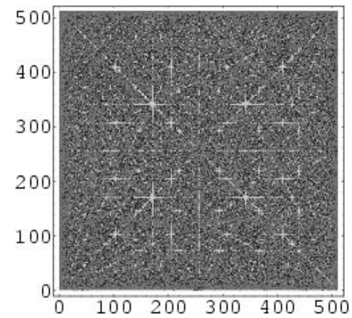
with $n=-N/2, ..., 0, ..., N/2$. There are $N+1$ values of n, so there is one relationship between the frequency components. Writing this out as per Press *et al.* (1989)

$$\mathscr{F}[f(t)]=\sum_{k=0}^{N-1} f_k e^{-2\pi i(n/N\Delta)k\Delta}\Delta=\Delta\sum_{k=0}^{N-1} f_k e^{-2\pi i n k/N}, \qquad (3)$$

and

$$F_n\equiv\sum_{k=0}^{N-1} f_k e^{-2\pi i n k/N}. \qquad (4)$$

The inverse transform is



$$f_k=\frac{1}{N}\sum_{n=0}^{N-1} F_n e^{2\pi i n k/N}. \qquad (5)$$

Note that $F_{-n}=F_{N-n}$, $n=1, 2, ...$, so an alternate formulation is

$$\nu_n=\frac{n}{N\Delta}, \qquad (6)$$

where the NEGATIVE frequencies $-\nu_c<\nu<0$ have $N/2+1\le n\le N-1$, POSITIVE frequencies $0<\nu<\nu_c$ have $1\le n\le N/2-1$, with zero frequency $n=0$. $n=N/2$ corresponds to both $\nu=\nu_c$ and $\nu=-\nu_c$. The discrete Fourier transform can be computed using a FAST FOURIER TRANSFORM.

The discrete Fourier transform is a special case of the Z-TRANSFORM. It can be computed for a list l of COMPLEX NUMBERS using the *Mathematica* command `Fourier[l]`.

The above plot shows the 2-D discrete Fourier transform of the reciprocals of the greatest common divisor GCD (i,j) for $i,j\in[1,512]$ (Trott 2000).

Discrete Set

A set S is discrete in a larger TOPOLOGICAL SPACE X if every point $x \in S$ has a NEIGHBORHOOD U such that $S \cap U = \{x\}$.. The points of S are then said to be ISOLATED (Krantz 1999, p. 63). Typically, a discrete set is either finite or COUNTABLY INFINITE. For example, the set of integers is discrete on the REAL LINE. Another example of an infinite discrete set is the set $\{1/n \quad \text{for all integers } n > 1\}$. On any reasonable space, a finite set is discrete. A set is discrete if it has the DISCRETE TOPOLOGY, that is, if every subset is open.

In the case of a subset S, as in the examples above, one uses the RELATIVE TOPOLOGY on S. Sometimes a discrete set is also closed. Then there cannot be any ACCUMULATION POINTS of a discrete set. On a COMPACT SET such as the SPHERE, a closed discrete set must be finite because of this.

Discrete Uniform Distribution

EQUALLY LIKELY OUTCOMES DISTRIBUTION

DiscreteDelta

KRONECKER DELTA

Discriminant

A discriminant is a quantity (usually invariant under certain classes of transformations) which characterizes certain properties of a quantity's ROOTS. The concept of the discriminant is used for BINARY QUADRATIC FORMS, ELLIPTIC CURVES, METRICS, MODULES, POLYNOMIALS, QUADRATIC CURVES, QUADRATIC FIELDS, QUADRATIC FORMS, and in the SECOND DERIVATIVE TEST.

See also DISCRIMINANT (BINARY QUADRATIC FORM), DISCRIMINANT (CIRCLE), DISCRIMINANT (CONIC SECTION), DISCRIMINANT (ELLIPTIC CURVE), DISCRIMINANT (METRIC), MODULAR DISCRIMINANT, DISCRIMINANT (MODULE), DISCRIMINANT (POLYNOMIAL), DISCRIMINANT (QUADRATIC CURVE), DISCRIMINANT (SECOND DERIVATIVE TEST)

Discriminant (Binary Quadratic Form)

The discriminant of a BINARY QUADRATIC FORM

$$au^2 + buv + cv^2$$

is defined by

$$d \equiv b^2 - 4ac.$$

It is equal to four times the corresponding DETERMINANT.

See also CLASS NUMBER

Discriminant (Circle)

In HOMOGENEOUS COORDINATES (x_1, x_2, x_3), the equation of a CIRCLE C is

$$a(x_1^2 + x_2^2) + 2fx_2x_3 + 2gx_1x_3 + cx_3^2 = 0.$$

The discriminant of this circle is defined as

$$\Delta = \begin{vmatrix} a & 0 & g \\ 0 & a & f \\ g & f & c \end{vmatrix} = a(ac - f^2 - g^2),$$

and the quadratic form $q(C) = ac - f^2 - g^2$ is the basic invariant.

See also DISCRIMINANT (CONIC SECTION)

References

Barth, W. and Bauer, T. "Poncelet Theorems." *Expos. Math.* **14**, 125–44, 1996.

Discriminant (Conic Section)

The discriminant of the general CONIC SECTION

$$ax_1^2 + bx_2^2 + cx_3^2 + 2fx_2x_3 + 2gx_1x_3 + 2hx_1x_2 = 0$$

is defined as

$$\Delta = \begin{vmatrix} a & h & g \\ h & b & f \\ g & f & c \end{vmatrix} = abc + 2fgh - af^2 - bg^2 - ch^2.$$

If $b = a$ and $g = h = 0$, then simplifies to the DISCRIMINANT of a CIRCLE.

See also DISCRIMINANT (CIRCLE)

References

Salmon, G. *Conic Sections, 6th ed.* New York: Chelsea, p. 266, 1960.

Discriminant (Elliptic Curve)

An ELLIPTIC CURVE is the set of solutions to an equation of the form

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6. \tag{1}$$

By changing variables, $y \to 2y + a_1x + a_3$, assuming the CHARACTERISTIC is not 2, the equation becomes

$$y^2 = 4x^3 + b_2x^2 + 2b_4x + b_6 \tag{2}$$

where

$$b_2 = a_1^2 + 4a_2 \tag{3}$$

$$b_4 = 2a_4 + a_1a_3 \tag{4}$$

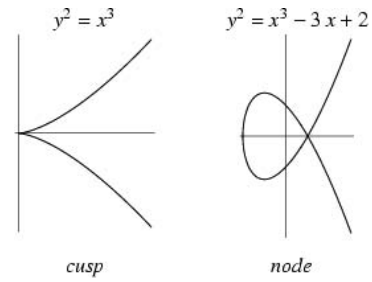
$$b_6 = a_3^2 + 4a_6. \tag{5}$$

Define also the quantity

$$b_8 = a_1^2a_6 + 4a_2a_6 - a_1a_3a_4 + a_2a_3^2 - a_4^2, \tag{6}$$

then the discriminant is given by

$$\Delta = -b_2^2b_8 - 8b_4^3 - 27b_6^2 + 9b_2b_4b_6. \tag{7}$$



The discriminant depends on the choice of equations, and can change after a change of variables, unlike the J-INVARIANT.

If the CHARACTERISTIC of the FIELD is neither 2 or 3, then its equation can be written as

$$y^2 = x^3 + \mathrm{A}x + \mathrm{B}, \tag{8}$$

in which case, the discriminant is given by

$$\Delta = -16(4\mathrm{A}^3 + 27\mathrm{B}^2). \tag{9}$$

Algebraically, the discriminant is nonzero when the right-hand side has three distinct roots. In the classical case of an ELLIPTIC CURVE over the COMPLEX NUMBERS, the discriminant has a geometric interpretation. If $\Delta \neq 0$, then the elliptic curve is nonsingular and has GENUS 1, i.e., it is a TORUS. If $\Delta = 0$ and $A = 0$, then it has a CUSP singularity, in which case there is one tangent direction at the singularity. If $\Delta = 0$ and $\mathrm{A} \neq 0$, then its singularity is called an ORDINARY DOUBLE POINT (or node), in which case the singularity has two distinct tangent directions.

Note that the discriminant of an ELLIPTIC CURVE is not the same as the DISCRIMINANT of the corresponding polynomial, but the two kinds of discriminants vanish for the same values of A and B.

See also ALGEBRAIC GEOMETRY, ELLIPTIC CURVE, FREY CURVE, ISOGENY, J-INVARIANT, LEGENDRE FORM, MINIMAL DISCRIMINANT, WEIERSTRASS FORM

References

Silverman, J. *The Arithmetic of Elliptic Curves.* New York: Springer-Verlag, 1986.

Discriminant (Elliptic Function)

If $y^2 = 4x^3 + b_2x^2 + 2b_4x + b_6$ and b_2 are the INVARIANTS of a WEIERSTRASS ELLIPTIC FUNCTION $a_1^2 + 4a_2$ with periods b_4 and $2a_4 + a_{1a_3}$, then the discriminant is defined by

$$b_6 \tag{1}$$

Letting $a_3^2 + 4a_6.$, then

$$\begin{aligned} b_8 &= a_1^2a_6 + 4a_2a_6 - a_1a_3a_4 + a_2a_3^2 - a_4^2,^{r>1}\,\Delta \\ &= -b_2^2b_8 - 8b_4^3 - 27b_6^2 + 9b_2b_4b_6. \\ &= y^2 = x^3 + \mathrm{A}x + \mathrm{B}, \end{aligned} \tag{2}$$

$$= \Delta = -16(4A^3 + 27B^2 \tag{3}$$

The FOURIER SERIES of for $\Delta \neq 0$, where H is the UPPER HALF-PLANE, is

$$A = 0 \qquad (4)$$

where $A \neq 0$, is the TAU FUNCTION, and $A \neq 0$, are integers (Apostol 1997, p. 20). The discriminant can also be expressed in terms of the DEDEKIND ETA FUNCTION $g\alpha\beta$ by

$$g \equiv \det(g_{\alpha,\beta}) = \begin{vmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{vmatrix} = g_{11}g_{22} - (g_{12})^2. \qquad (5)$$

(Apostol 1997, p. 51).

References

Apostol, T. M. "The Discriminant $\bar{g}$" and "The Fourier Expansions of and $\bar{g} = D^2 g$.." §1.11 and 1.15 in *Modular Functions and Dirichlet Series in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 14 and 20–2, 1997.

Discriminant (Metric)

Given a METRIC $g_{\alpha\beta}$, the discriminant is defined by

$$g \equiv \det(g_{\alpha,\beta}) = \begin{vmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{vmatrix} = g_{11}g_{22} - (g_{12})^2. \qquad (1)$$

Let g be the discriminant and $\bar{g}$ the transformed discriminant, then

$$\bar{g} = D^2 g \qquad (2)$$

$$g = \bar{D}^2 \bar{g}, \qquad (3)$$

where

$$D \equiv \frac{\partial(u^1, u^2)}{\partial(\bar{u}^1, \bar{u}^2)} = \begin{vmatrix} \frac{\partial u^1}{\partial \bar{u}^1} & \frac{\partial u^1}{\partial \bar{u}^2} \\ \frac{\partial u^2}{\partial \bar{u}^1} & \frac{\partial u^2}{\partial \bar{u}^2} \end{vmatrix}. \qquad (4)$$

$$\bar{D} \equiv \frac{\partial(\bar{u}^1, \bar{u}^2)}{\partial(u^1, u^2)} = \begin{vmatrix} \frac{\partial \bar{u}^1}{\partial u^1} & \frac{\partial \bar{u}^1}{\partial u^2} \\ \frac{\partial \bar{u}^2}{\partial u^1} & \frac{\partial \bar{u}^2}{\partial u^2} \end{vmatrix}. \qquad (5)$$

Discriminant (Module)

Let a MODULE M in an INTEGRAL DOMAIN D_1 for $R(\sqrt{D})$ be expressed using a two-element basis as

$$M = [\xi_1, \xi_2],$$

where ξ_1 and ξ_2 are in D_1. Then the DIFFERENT of the MODULE is defined as

$$\Delta = \Delta(M) = \begin{vmatrix} \xi_1 & \xi_2 \\ \xi_2' & \xi_2' \end{vmatrix} = \xi_1\xi_2' - \xi_1'\xi_2$$

and the discriminant is defined as the square of the DIFFERENT (Cohn 1980).

For IMAGINARY QUADRATIC FIELDS $\mathbb{Q}(\sqrt{n})$ (with $n < 0$), the discriminants are given in the following table.

-1	-2^2	-33	$-2^2\cdot3\cdot11$	-67	-67
-2	-2^3	-34	$-2^3\cdot17$	-69	$-2^2\cdot3\cdot23$
-3	-3	-35	$-5\cdot7$	-70	$-2^3\cdot5\cdot7$
-5	$-2^2\cdot5$	-37	$-2^2\cdot37$	-71	-71
-6	$-2^3\cdot3$	-39	$-3\cdot13$	-73	$-2^2\cdot73$
-7	-7	-41	$-2^2\cdot41$	-74	$-2^3\cdot37$
-10	$-2^3\cdot5$	-42	$-2^3\cdot3\cdot7$	-77	$-2^2\cdot7\cdot11$
-11	-11	-43	-43	-78	$-2^3\cdot3\cdot13$
-13	$-2^2\cdot13$	-46	$-2^3\cdot23$	-79	-79
-14	$-2^3\cdot7$	-47	-47	-82	$-2^3\cdot41$
-15	$-3\cdot5$	-51	$-3\cdot17$	-83	-83
-17	$-2^2\cdot17$	-53	$-2^2\cdot53$	-85	$-2^2\cdot5\cdot17$
-19	-19	-55	$-5\cdot11$	-86	$-2^3\cdot43$
-21	$-2^2\cdot3\cdot7$	-57	$-2^2\cdot3\cdot19$	-87	$-3\cdot29$
-22	$-2^3\cdot11$	-58	$-2^3\cdot29$	-89	$-2^2\cdot89$
-23	-23	-59	-59	-91	$-7\cdot13$
-26	$-2^3\cdot13$	-61	$-2^2\cdot61$	-93	$-2^2\cdot3\cdot31$
-29	$-2^2\cdot29$	-62	$-2^3\cdot31$	-94	$-2^3\cdot47$
-30	$-2^3\cdot3\cdot5$	-65	$-2^2\cdot5\cdot13$	-95	$-5\cdot19$
-31	-31	-66	$-2^3\cdot3\cdot11$	-97	$-2^2\cdot97$

The discriminants of REAL QUADRATIC FIELDS $\mathbb{Q}(\sqrt{n})$ $(n > 0)$ are given in the following table.

2	2^3	34	$2^3\cdot17$	67	$67\cdot2^2$
3	$3\cdot2^2$	35	$7\cdot2^2\cdot5$	69	$3\cdot23$
5	5	37	37	70	$7\cdot2^3\cdot5$
6	$3\cdot2^3$	38	$19\cdot2^3$	71	$71\cdot2^2$
7	$7\cdot2^2$	39	$3\cdot2^2\cdot13$	73	73
10	$2^3\cdot5$	41	41	74	$2^3\cdot37$
11	$11\cdot2^2$	42	$3\cdot2^3\cdot7$	77	$7\cdot11$
13	13	43	$43\cdot2^2$	78	$3\cdot2^3\cdot13$
14	$7\cdot2^3$	46	$23\cdot2^3$	79	$79\cdot2^2$
15	$3\cdot2^2\cdot5$	47	$47\cdot2^2$	82	$2^3\cdot41$
17	17	51	$3\cdot2^2\cdot17$	83	$83\cdot2^2$
19	$19\cdot2^2$	53	53	85	$5\cdot17$

21	$3 \cdot 7$	55	$11 \cdot 2^2 \cdot 5$	86	$43 \cdot 2^3$
22	$11 \cdot 2^3$	57	$3 \cdot 19$	87	$3 \cdot 2^2 \cdot 13$
23	$23 \cdot 2^2$	58	$2^3 \cdot 29$	89	89
26	$2^3 \cdot 13$	59	$59 \cdot 2^2$	91	$7 \cdot 2^2 \cdot 13$
29	29	61	61	93	$3 \cdot 31$
30	$3 \cdot 2^3 \cdot 5$	62	$31 \cdot 2^3$	94	$47 \cdot 2^3$
31	$31 \cdot 2^2$	65	$5 \cdot 13$	95	$19 \cdot 2^2 \cdot 5$
33	$3 \cdot 11$	66	$3 \cdot 2^3 \cdot 11$	97	97

Discriminant (Polynomial)

The PRODUCT of the SQUARES of the differences of the POLYNOMIAL ROOTS r_i. The discriminant of a polynomial is only defined up to sign. For a POLYNOMIAL

$$a_n z^n + a_{n-1} z^{n-1} + \cdots + a_1 z + a_0 = 0 \qquad (1)$$

of degree n,

$$D_n = \prod_{\substack{i,j \\ i<j}}^{n} (r_i - r_j)^2. \qquad (2)$$

It is also common to consider discriminants D'_n for $a_n \equiv 1$ or discriminants D''_n obtained from D_n by multiplying by $a_n^{2(n-1)}$. If desired, powers a_n can be inserted mentally so that each term is of degree $2(n-1)$ and the whole expression is divided by $a_n^{2(n-1)}$..

The discriminant is closely related to RESULTANTS and can be implemented in *Mathematica* as

```
Discriminant[p_?PolynomialQ,x_] :=
   With[{n = Exponent[p,x]},     Cancel[
     ((-1)^(n(n-1)/2)Resultant[p,D[p,x],x])/
      Coefficient[p,x,n]^(2n-1)
     ]
   ]
```

The discriminant of the QUADRATIC EQUATION

$$a_2 z^2 + a_1 z + a_0 = 0 \qquad (3)$$

is given by

$$D_2 = \frac{a_1^2 - 4a_0 a_2}{a_2^2}. \qquad (4)$$

The discriminant of the CUBIC EQUATION

$$a_3 z^3 + a_2 z^2 + a_1 z + a_0 = 0 \qquad (5)$$

is given by

$$D_3 = \frac{a_1^2 a_2^2 - 4a_0 a_2^3 - 4a_1^3 a_3 + 18 a_0 a_1 a_2 a_3 - 27 a_0^2 a_3^2}{a_3^4} \qquad (6)$$

The discriminant of a QUARTIC EQUATION

$$z^4 + a_3 z^3 + a_2 z^2 + a_1 z + a_0 = 0 \qquad (7)$$

is

$$\begin{aligned} D_4 = \frac{1}{a_4^6} [& (a_1^2 a_2^2 a_3^2 - 4a_1^3 a_3^3 - 4a_1^2 a_2^3 a_4 \\ & + 18 a_1^3 a_2 a_3 a_4 - 27 a_1^4 a_4^2 + 256 a_0^3 a_4^3) \\ & + a_0(-4a_2^3 a_3^3 + 18 a_1 a_2 a_3^3 + 16 a_2^4 a_4 \\ & - 80 a_1 a_2^2 a_3 a_4 - 6 a_1^2 a_3^2 a_4 + 144 a_1^2 a_2 a_4^2) \\ & + a_0^2(-27 a_3^4 + 144 a_2 a_3^2 a_4 - 128 a_2^2 a_4^2 - 192 a_1 a_3 a_4^2)] \end{aligned}$$

(Beeler *et al.* 1972, Item 4).

Discriminant (Quadratic Curve)

Given a general QUADRATIC CURVE

$$Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0, \qquad (1)$$

the quantity X is known as the discriminant, where

$$X \equiv B^2 - 4AC, \qquad (2)$$

and is invariant under ROTATION. Using the COEFFICIENTS from QUADRATIC EQUATIONS for a rotation by an angle θ,

$$A' = \frac{1}{2} A[1 + \cos(2\theta)] + \frac{1}{2} \mathrm{B} \sin(2\theta) + \frac{1}{2} C[1 - \cos(2\theta)]$$

$$\frac{A + C}{2} + \frac{B}{2} \sin(2\theta) + \frac{A - C}{2} \cos(2\theta) \qquad (3)$$

$$\mathrm{B}' = G \cos\left(2\theta + \delta - \frac{\pi}{2}\right) = G \sin(2\theta + \delta) \qquad (4)$$

$$C' = \frac{1}{2} A[1 - \cos(2\theta)] - \frac{1}{2} B \sin\left(2\theta + \frac{1}{2}\right) C[1 + \cos(2\theta)]$$

$$= \frac{A + C}{2} - \frac{B}{2} \sin(2\theta) + \frac{C - A}{2} \cos(2\theta). \qquad (5)$$

Now let

$$G \equiv \sqrt{B^2 + (A-C)^2} \quad (6)$$

$$\delta \equiv \tan^{-1}\left(\frac{B}{C-A}\right) \quad (7)$$

$$\delta_2 \equiv \tan^{-1}\left(\frac{A-C}{B}\right) = -\cot^{-1}\left(\frac{B}{C-A}\right), \quad (8)$$

and use

$$\cot^{-1}(x) \equiv \frac{1}{2}\pi - \tan^{-1}(x) \quad (9)$$

$$\delta_2 = \delta - \frac{1}{2}\pi \quad (10)$$

to rewrite the primed variables

$$A' = \frac{A+C}{2} + \frac{1}{2}G\cos(2\theta + \delta) \quad (11)$$

$$B' = B\cos(2\theta) + (C-A)\sin(2\theta) = G(2\theta + \delta_2) \quad (12)$$

$$C' = \frac{A+C}{2} - \frac{1}{2}G\cos(2\theta + \delta). \quad (13)$$

From (11) and (13), it follows that

$$4A'C' = (A+C)^2 - G^2\cos(2\theta + \delta). \quad (14)$$

Combining with (12) yields, for an arbitrary θ

$$\begin{aligned} X &\equiv B'^2 - 4A'C' \\ &= G^2\sin^2(2\theta+\delta) + G^2\cos^2(2\theta+\delta) - (A+C)^2 \\ &= G^2 - (A+C)^2 = B^2 + (A-C)^2 - (A+C)^2 \\ &= B^2 - 4AC, \end{aligned} \quad (15)$$

which is therefore invariant under rotation. This invariant therefore provides a useful shortcut to determining the shape represented by a QUADRATIC CURVE. Choosing θ to make $B' = 0$ (see QUADRATIC EQUATION), the curve takes on the form

$$A'x^2 + C'y^2 + D'x + E'y + F = 0. \quad (16)$$

COMPLETING THE SQUARE and defining new variables gives

$$A'x'^2 + C'y'^2 = H. \quad (17)$$

Without loss of generality, take the sign of H to be positive. The discriminant is

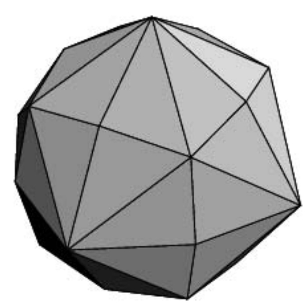
$$X = B'^2 + 4A'C' = -4A'C'. \quad (18)$$

Now, if $-4A'C' < 0$, then A' and C' both have the same sign, and the equation has the general form of an ELLIPSE (if A' and B' are positive). If $-4A'C' > 0$, then A' and C' have opposite signs, and the equation has the general form of a HYPERBOLA. If $-4A'C' = 0$, then either A' or C' is zero, and the equation has the general form of a PARABOLA (if the NONZERO A' or C' is positive). Since the discriminant is invariant, these conclusions will also hold for an arbitrary choice of θ, so they also hold when $-4A'C'$ is replaced by the original $B^2 - 4AC$. The general result is

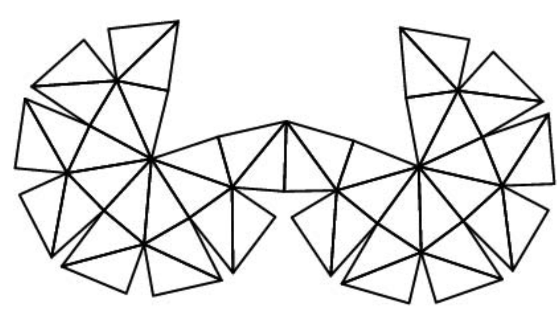
1. If $B^2 - 4AC < 0$, the equation represents an ELLIPSE, a CIRCLE (degenerate ELLIPSE), a POINT (degenerate CIRCLE), or has no graph.
2. If $B^2 - 4AC > 0$, the equation represents a HYPERBOLA or pair of intersecting lines (degenerate HYPERBOLA).
3. If $B^2 - 4AC = 0$, the equation represents a PARABOLA, a LINE (degenerate PARABOLA), a pair of PARALLEL lines (degenerate PARABOLA), or has no graph.

Discriminant (Quadratic Form)

DISCRIMINANT (BINARY QUADRATIC FORM)



Discriminant (Second Derivative Test)



$$D \equiv f_{xx}f_{yy} - f_{xy}f_{yx} = f_{xx}f_{yy} - f_{xy}^2,$$

where f_{ij} are PARTIAL DERIVATIVES.

Disdyakis Dodecahedron

The DUAL POLYHEDRON of the Archimedean GREAT RHOMBICUBOCTAHEDRON A_3 and Wenninger dual W_{15}, also called the HEXAKIS OCTAHEDRON. If the original GREAT RHOMBICUBOCTAHEDRON has unit side lengths, then the resulting dual has edge lengths

$$s_1 = \frac{2}{7}\sqrt{30 - 3\sqrt{2}} \quad (1)$$

$$s_2 = \frac{3}{7}\sqrt{6\left(2 + \sqrt{2}\right)} \quad (2)$$

$$s_3 = \frac{2}{7}\sqrt{6\left(10 + \sqrt{2}\right)}. \quad (3)$$

The INRADIUS is

$$r = 3\sqrt{\frac{2}{97}\left(15 + 8\sqrt{2}\right)}. \quad (4)$$

Scaling the disdyakis dodecahedron so that $s_1 = 1$ gives a solid with SURFACE AREA and VOLUME

$$S = \frac{6}{7}\sqrt{783 + 436\sqrt{2}} \quad (5)$$

$$V = \frac{1}{7}\sqrt{3\left(2194 + 1513\sqrt{2}\right)}. \quad (6)$$

Disjoint Sets

Two SETS A_1 and A_2 are disjoint if their INTERSECTION $A_1 \cap A_2 \equiv \emptyset$, where $\emptyset$ is the EMPTY SET. n sets A_1, A_2, ..., A_n are disjoint if $A_i \cap A_j \equiv \emptyset$ for $i \neq j$. For example, $\{A, B, C\}$ and $\{D, E\}$ are disjoint, but $\{A, B, C\}$ and $\{C, D, E\}$ are not. Disjoint sets are also said to be mutually exclusive or independent.

See also EMPTY SET, INDEPENDENT SET, INTERSECTION, SET

Disjoint Union

The disjoint union of two SETS A and B is a BINARY OPERATOR that combines all distinct elements of a pair of given sets, while retaining the original set membership as a distinguishing characteristic of the union set. The disjoint union is denoted

$$A \cup^* B = (A \times \{0\}) \cup (B \times \{1\}) \equiv A^* \cup B^*,$$

where $A \times S$ is a SET DIRECT PRODUCT. For example, the disjoint union of sets $A = \{1, 2, 3, 4, 5\}$ and $B = \{1, 2, 3, 4, 5\}$ can be computed by finding

$$A^* = \{(1,0), (2,0), (3,0), (4,0), (5,0)\}$$

$$B^* = \{(1,1), (2,1), (3,1), (4,1)\},$$

so

$$A \cup^* B = A^* \cup B^*$$

$$= \{(1,0), (2,0), (3,0), (4,0), (5,0), (1,1), (2,1), (3,1), (4,1)\}$$

Disjunctive Game

NIM-HEAP

Disjunctive Normal Form

A statement is in disjunctive normal form if it is a DISJUNCTION (sequence of ORs) consisting of one or more disjuncts, each of which is a CONJUNCTION (AND) of one or more statement letters and negations of statement letters. Examples of disjunctive normal forms include

$$A \tag{1}$$

$$(A \wedge B) \vee (!A \wedge C) \tag{2}$$

$$(A \wedge B \wedge !A) \vee (C \wedge !B) \vee (A \wedge !C) \tag{3}$$

$$(A \wedge B) \tag{4}$$

$$A \vee (B \wedge C), \tag{5}$$

where $\vee$ denotes OR, $\wedge$ denotes AND, and ! denotes NOT. Every statement in logic consisting of a combination of multiple $\wedge$, $\vee$, and !s can be written in conjunctive normal form.

See also CONJUNCTIVE NORMAL FORM

Disk

An n-D disk (or DISC) of RADIUS r is the collection of points of distance $\leq r$ (CLOSED DISK) or $< r$ (OPEN DISK) from a fixed point in EUCLIDEAN n-space. A disk is the SHADOW of a BALL on a PLANE PERPENDICULAR to the BALL-RADIANT POINT line.

The n-disk for $n \geq 3$ is called a BALL, and the boundary of the n-disk is a $(n-1)$-HYPERSPHERE. The standard n-disk, denoted $\mathbb{D}^n$ (or $\mathbb{B}^n$), has its center at the ORIGIN and has RADIUS $r = 1$.

See also BALL, CLOSED DISK, DISK COVERING PROBLEM, FIVE DISKS PROBLEM, HYPERSPHERE, LOWER HALF-DISK, MERGELYAN-WESLER THEOREM, OPEN DISK, POLYDISK, SPHERE, UNIT DISK, UPPER HALF-DISK

Disk Algebra

This entry contributed by RONALD M. AARTS

A disk algebra is an ALGEBRA of functions which are analytic on the OPEN UNIT DISK in C and continuous up to the boundary. A representative measure for a point x in the CLOSED DISK is a nonnegative MEASURE m such that Int($f\ dm$)$=f(x)$ for all f in A. These measures form a COMPACT, CONVEX SET M_x in the linear space of all measures.

See also ALGEBRA

Disk Covering Problem

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Given a UNIT DISK, find the smallest RADIUS $r(n)$ required for n equal disks to completely cover the UNIT DISK. For a symmetrical arrangement with $n = 5$ (the FIVE DISKS PROBLEM), $r(5) = \phi - 1 = 1/\phi = 0.6180340\ldots$, where ϕ is the GOLDEN RATIO. However, the radius can be reduced in the general disk covering problem where symmetry is not required. The first few such values are

$$r(1) = 1$$

$$r(2) = 1$$

$$r(3) = \frac{1}{2}\sqrt{3}$$

$$r(4) = \frac{1}{2}\sqrt{2}$$

$$r(5) = 0.609382864\ldots$$

$$r(6) = 0.555$$

$$r(7) = \frac{1}{2}$$

$$r(8) = 0.437$$

$$r(9) = 0.422$$

$$r(10) = 0.398.$$

Here, values for $n = 6$, 8, 9, 10 were obtained using computer experimentation by Zahn (1962). The value $r(5)$ is equal to $\cos(\theta + \phi/2)$, where θ and ϕ are solutions to

$$2\sin\theta - \sin\left(\theta + \frac{1}{2}\phi + \psi\right) - \sin\left(\psi - \theta - \frac{1}{2}\phi\right) = 0 \tag{1}$$

$$2\sin\phi - \sin\left(\theta + \frac{1}{2}\phi + \chi\right) - \sin\left(\chi - \theta - \frac{1}{2}\phi\right) = 0 \tag{2}$$

$$2\sin\theta + \sin(\chi + \theta) - \sin(\chi - \theta) - \sin(\psi + \phi) \\ -\sin(\psi - \phi) - 2\sin(\psi - 2\theta) = 0 \tag{3}$$

$$\cos(2\psi - \chi + \phi) - \cos(2\psi + \chi - \phi) - 2\cos\chi \\ +\cos(2\psi + \chi - 2\theta) + \cos(2\psi - \chi - 2\theta) = 0 \tag{4}$$

(Neville 1915). It is also given by $1/x$, where x is the largest real root of

$$a(y)x^6 - b(y)x^5 + c(y)x^4 - d(y)x^3 + e(y)x^2 - f(y)x + g(y) \\ = 0 \tag{5}$$

maximized over all y, subject to the constraints

$$\sqrt{2} < x < 2y + 1 \tag{6}$$

$$-1 < y < 1, \tag{7}$$

and with

$$a(y) = 80y^2 + 64y \tag{8}$$

$$b(y) = 416y^3 + 384y^2 + 64y \tag{9}$$

$$c(y) = 848y^4 + 928y^3 + 352y^2 + 32y \tag{10}$$

$$d(y) = 768y^5 + 992y^4 + 736y^3 + 288y^2 + 96y$$

$$e(y) = 256y^6 + 384y^5 + 592y^4 + 480y^3 + 336y^2 + 96y + 16 \tag{11}$$

$$f(y) = 128y^5 + 192y^4 + 256y^3 + 160y^2 + 96y + 32 \tag{12}$$

$$g(y) = 64y^2 + 64y + 16 \tag{13}$$

(Bezdek 1983, 1984).

Letting $N(\varepsilon)$ be the smallest number of DISKS of RADIUS ε needed to cover a disk D, the limit of the ratio of the AREA of D to the AREA of the disks is given by

$$\lim_{\varepsilon \to 0^+} \frac{1}{\varepsilon^2 N(\varepsilon)} = \frac{3\sqrt{3}}{2\pi} \tag{14}$$

(Kershner 1939, Verblunsky 1949).

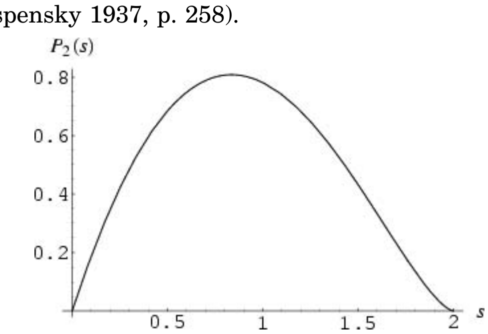
Disk Lattice Points

GAUSS'S CIRCLE PROBLEM

Disk Line Picking

Using DISK POINT PICKING,

$$x = \sqrt{r}\,\cos\theta \tag{1}$$



$$y = \sqrt{r}\,\sin\theta \tag{2}$$

for $r \in [0, 1]$, $\theta \in [0, 2\pi)$, choose two points at random in a UNIT DISK and find the distribution of distances s between the two points. Without loss of generality, take the first point as $(r, \theta) = (r_1, 0)$ and the second point as (r_2, θ). Then>

$$\bar{s} = \frac{v\int_0^1\int_0^1\int_0^{2\pi} \sqrt{r_1 + r_2 - 2\sqrt{r_1 r_2 \cos\theta}}\,dr_1\,dr_2\,d\theta}{\int_0^1\int_0^1\int_0^{2\pi} dr_1\,dr_2\,d\theta} \tag{3}$$

$$= \frac{128}{45\pi} \tag{4}$$

(Uspensky 1937, p. 258).

This is a special case of BALL LINE PICKING with $n = 2$, so the full probability function for a disk of radius R is

$$P_2(s) = \frac{4s}{\pi R^2}\cos^{-1}\left(\frac{s}{2R}\right) - \frac{2s^2}{\pi R^3}\sqrt{1 - \frac{s^2}{4R^2}} \tag{5}$$

(Solomon 1978, p. 129).

Disk Packing

CIRCLE PACKING

Disk Point Picking

To generate random points over the UNIT DISK, it is *incorrect* to use two uniformly distributed variables $r \in [0, 1]$, and $\theta \in [0, 2\pi)$, and then take

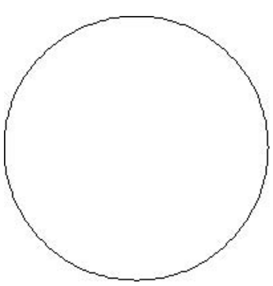
$$x = r \cos\theta \quad (1)$$

$$y = r \sin\theta. \quad (2)$$

Because the area element is given by

$$dA = 2\pi r dr, \quad (3)$$

this gives a concentration of points in the center (left figure above).
The correct transformation is instead given by



$$x = \sqrt{r} \cos\theta \quad (4)$$

$$y = \sqrt{r} \sin\theta \quad (5)$$

(right figure above).

See also CIRCLE POINT PICKING, DISK LINE PICKING, POINT PICKING, SPHERE POINT PICKING

Disk Triangle Picking

Pick three points $P = (x_1, y_1)$, $Q = (x_2, y_2)$, and $R = (x_3, y_3)$ distributed independently and uniformly in a UNIT DISK K. Then the average area of the TRIANGLE determined by these points is

$$\bar{A} = \frac{\iint_{P\in K}\iint_{Q\in K}\iint_{R\in K} \frac{1}{2}\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix} dy_3 dy_3 dy_1 dx_3 dx_2 dx_1}{\iint_{P\in K}\iint_{Q\in K}\iint_{R\in K} dy_3 dy_3 dy_1 dx_3 dx_2 dx_1} \quad (1)$$

which can be evaluated using CROFTON'S FORMULA and polar coordinates to yield $\bar{A} = 35/(48\pi^2)$ (Woolhouse 1967; Solomon 1987; Pfiefer 1989). This problem is very closely related to SYLVESTER'S FOUR-POINT PROBLEM, and can be derived as the limit as $n \to \infty$ of the general POLYGON TRIANGLE PICKING problem.

The probability P_2 that three random points in a disk form an ACUTE TRIANGLE is

$$P_2 = \frac{4}{\pi^2} - \frac{1}{8} \quad (2)$$

(Woolhouse 1886). The problem was generalized by Hall (1982) to n-D BALL TRIANGLE PICKING, and Buchta (1986) gave closed form evaluations for Hall's integrals.

Let the VERTICES of a triangle in n-D be NORMAL (GAUSSIAN) variates. The probability that a Gaussian triangle in n-D is OBTUSE is

$$P_n = \frac{3\Gamma(n)}{\Gamma^2\left(\frac{1}{2}n\right)} \int_0^{1/3} \frac{x^{(n-2)/2}}{(1+x)^n} dx$$

$$= \frac{3\Gamma(n)}{\Gamma^2\left(\frac{1}{2}n\right)^{2n-1}} \int_0^{\pi/3} \sin^{n-1}\theta d\theta$$

$$= \frac{6\Gamma(n)_2F_1\left(\frac{1}{2}n, n; 1+\frac{1}{2}n; -\frac{1}{3}\right)}{3^{n/2} n \Gamma^2\left(\frac{1}{2}n\right)}, \quad (3)$$

where $\Gamma(n)$ is the GAMMA FUNCTION and ${}_2F_1(a, b; c; x)$ is the HYPERGEOMETRIC FUNCTION. For EVEN $n \equiv 2k$,

$$P_{2k} = 3 \sum_{j=k}^{2k-1} \binom{2k-1}{j} \left(\frac{1}{4}\right)^j \left(\frac{3}{4}\right)^{2k-1-j} \quad (4)$$

(Eisenberg and Sullivan 1996). The first few cases are explicitly

$$P_2 = \frac{3}{4} = 0.75 \quad (5)$$

$$P_3 = 1 - \frac{3\sqrt{3}}{4\pi} = 0.586503\ldots \quad (6)$$

$$P_4 = \frac{15}{32} = 0.46875 \quad (7)$$

$$P_5 = 1 - \frac{9\sqrt{3}}{8\pi} = 0.37975499\ldots \quad (8)$$

Disk-Cyclide Coordinates

A coordinate system defined by the transformation equations

$$x = \frac{a}{\Lambda}\text{cn } \mu \text{ cn } \nu \cos\psi \quad (1)$$

$$y = \frac{a}{\Lambda}\text{cn } \mu \text{ cn } \nu \sin\psi \quad (2)$$

$$z = \frac{a}{\Lambda}\text{sn } \mu \text{ dn } \mu \text{ sn } \nu \text{ dn } \nu, \quad (3)$$

where

$$\Lambda \equiv 1 - \text{dn}^2\mu \text{ sn}^2 v \quad (4)$$

and for $\mu \in [0, K]$, $\nu \in [0, K']$, and $\psi \in [0, 2pi)$.. Surfaces of constant μ are given by the cyclides of rotation

$$\left(\frac{x^2 + y^2}{a^2\text{cn}^2\mu} + \frac{k^2\text{sn}^2\mu}{a^2\text{dn}^2\mu}z^2\right)^2 - \frac{2(x^2 + y^2)}{a^2\text{cn}^2\mu} - \frac{2k^2\text{sn}^2\mu}{a^2\text{dn}^2\mu}z^2 + 1 = 0' \quad (5)$$

surfaces of constant ν by the disk cyclides

$$\left[\frac{\text{cn}^2\nu}{a^2}(x^2 + y^2) + \frac{k'^2\text{sn}^2\nu}{a^2\text{dn}^2\nu}z^2\right]^2 - \frac{2\text{cn}^2\nu}{a^2}(x^2 + y^2) - \frac{2k'^2\text{sn}^2\nu}{a^2\text{dn}^2\nu}z^2 + 1 = 0, \quad (6)$$

and surfaces of constant ψ by the half-planes

$$\tan\psi = \frac{y}{x}. \quad (7)$$

Dispersion (Sequence)

An array $B = b_{ij}$, $i, j \geq 1$ of POSITIVE INTEGERS is called a dispersion if

1. The first column of B is a strictly increasing sequence, and there exists a strictly increasing sequence $\{s_k\}$ such that
2. $b_{12} = s_1 \geq 2$,
3. The complement of the SET $\{b_{i1} : i \geq 1\}$ is the SET $\{s_k\}$,
4. $b_{ij} = s_{bi,j-1}$ for all $j \geq 3$ for $i = 1$ and for all $g \geq 2$ for all $i \geq 2$..

If an array $B = b_{ij}$, is a dispersion, then it is an INTERSPERSION.

Dispersion Numbers

MAGIC GEOMETRIC CONSTANTS

Dispersion Relation

Any pair of equations giving the REAL PART of a function as an integral of its IMAGINARY PART and the IMAGINARY PART as an integral of its REAL PART. Dispersion relationships imply causality in physics. Let

$$f(x_0) \equiv u(x_0) + iv(x_0), \tag{1}$$

then

$$u(x_0) = \frac{1}{\pi} PV \int_{-\infty}^{\infty} \frac{v(x)dx}{x - x_0} \tag{2}$$

$$v(x_0) = -\frac{1}{\pi} PV \int_{-\infty}^{\infty} \frac{u(x)dx}{x - x_0}, \tag{3}$$

where PV denotes the CAUCHY PRINCIPAL VALUE and $u(x_0)$ and $v(x_0)$ are HILBERT TRANSFORMS of each other. If the COMPLEX function is symmetric such that $f(-x) = f^*(x)$, then

$$u(x_0) = \frac{2}{\pi} PV \int_0^{\infty} \frac{xv(x)dx}{x^2 - x_0^2} \tag{4}$$

$$v(x_0) = -\frac{2}{\pi} PV \int_0^{\infty} \frac{xu(x)dx}{x^2 - x_0^2}. \tag{5}$$

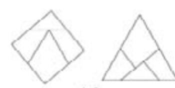
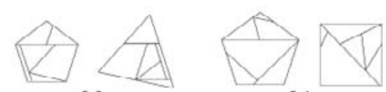
Dissection

Any two rectilinear figures with equal AREA can be dissected into a finite number of pieces to form each other. This is the WALLACE-BOLYAI-GERWEIN THEOREM. For minimal dissections of a TRIANGLE, PENTAGON, and OCTAGON into a SQUARE, see Stewart (1987, pp. 169–70) and Ball and Coxeter (1987, pp. 89–1). The TRIANGLE to SQUARE dissection (HABERDASHER'S PROBLEM) is particularly interesting because it can be built from hinged pieces which can be folded and unfolded to yield the two shapes (Gardner 1961; Stewart 1987, p. 169; Pappas 1989; Steinhaus 1983, pp. 3–; Wells 1991, pp. 61–2).



Laczkovich (1988) proved that the CIRCLE can be squared in a finite number of dissections (($\sim 10^{50}$).). Furthermore, any shape whose boundary is composed of smoothly curving pieces can be dissected into a SQUARE.

The situation becomes considerably more difficult moving from 2-D to 3-D. In general, a POLYHEDRON cannot be dissected into other POLYHEDRA of a specified type. A CUBE *can* be dissected into n^3 CUBES, where n is any INTEGER. In 1900, Dehn proved that not every PRISM can be dissected into a TETRAHEDRON (Lenhard 1962, Ball and Coxeter 1987) The third of HILBERT'S PROBLEMS asks for the determination of two TETRAHEDRA which cannot be decomposed into congruent TETRAHEDRA directly or by adjoining congruent TETRAHEDRA. Max Dehn showed this could not be done in 1902, and W. F. Kagon obtained the same result independently in 1903. A quantity growing out of Dehn's work which can be used to analyze the possibility of performing a given solid dissection is the DEHN INVARIANT.



The table below is an updated version of the one given in Gardner (1991, p. 50). Many of the improvements are due to G. Theobald (Frederickson 1997). The minimum number of pieces known to dissect a regular n-gon (where n is a number in the first column) into a k-gon (where k is a number is the bottom row) is read off by the intersection of the corresponding row and column. In the table, $\{n\}$ denotes a regular n-gon, GR a GOLDEN RECTANGLE, GC a GREEK CROSS, LC a LATIN CROSS, MC a MALTESE CROSS, SW a SWASTIKA, $\{5/2\}$ a five-point star (solid PENTAGRAM), $\{6/2\}$ a six-point star (i.e., HEXAGRAM or solid STAR OF DAVID), and $\{8/3\}$ the solid OCTAGRAM.

Dissection Puzzles

A puzzle in which one object is to be converted to another by making a finite number of cuts and reassembling it. The cuts are often, but not always, restricted to straight lines. Sometimes, a given puzzle is precut and is to be re-assembled into two or more given shapes.

See also CUNDY AND ROLLETT'S EGG, PYTHAGOREAN SQUARE PUZZLE, T-PUZZLE, TANGRAM

Dissipative System

A DYNAMICAL SYSTEM in which the PHASE SPACE volume contracts along a trajectory. This means that the generalized DIVERGENCE is less than zero,

$$\frac{\partial f_i}{\partial x_i} < 0,$$

where EINSTEIN SUMMATION has been used.

See also DYNAMICAL SYSTEM, PHASE SPACE

Dissymmetric

An object that is not superimposable on its MIRROR IMAGE is said to be disymmetric. All asymmetric objects are dissymmetric, and an object with no IMPROPER ROTATION (rotoinversion) axis must also be disymmetric. The opposite of dissymmetric is ENANTIOMORPHOUS.

See also AMPHICHIRAL KNOT, CHIRAL, DISSYMMETRIC, ENANTIOMER, ENANTIOMORPHOUS, HANDEDNESS, MIRROR IMAGE, REFLEXIBLE

Distance

The distance between two points is the length of the path connecting them. In the plane, the distance between points (x_1, y_1) and (x_2, y_2) is given by the PYTHAGOREAN THEOREM,

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}. \tag{1}$$

In Euclidean 3-space, the distance between points (x_1, y_1, z_1) and (x_2, y_2, z_2) is

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}. \tag{2}$$

In general, the distance between points $\mathbf{x}$ and $\mathbf{y}$ in a EUCLIDEAN SPACE $\mathbb{R}^n$ is given by

$$d = |\mathbf{x} - \mathbf{y}| = \sqrt{\sum_{i=1}^{n} |x_i - y_i|^2}. \tag{3}$$

For curved or more complicated surfaces, the so-called METRIC can be used to compute the distance

between two points by integration. When unqualified, "the" distance generally means the *shortest* distance between two points. For example, there are an infinite number of paths between two points on a SPHERE but, in general, only a single shortest path. The *shortest* distance between two points is the length of a so-called GEODESIC between the points. In the case of the sphere, the geodesic is a segment of a GREAT CIRCLE containing the two points.

Let $\gamma(t)$ be a smooth curve in a MANIFOLD M from x to y with $\gamma(0)=x$. and $\gamma(1)=y$.. Then $\gamma'(t)\in T_{\gamma(t)}$, where T_x is the TANGENT SPACE of M at x. The LENGTH of γ with respect to the Riemannian structure is given by

$$\int_0^1 \|\gamma'(t)\|_{\gamma(t)}dt, \tag{4}$$

and the distance $d(x,y)$ between x and y is the shortest distance between x and y given by

$$d(x,y)=\inf_{\gamma ix\ to\ y}\int\|\gamma'(t)\|_{\gamma(t)}dt. \tag{5}$$

In order to specify the relative distances of $n>1$ points in the plane, $1+2(n-2)=2n-3$ coordinates are needed, since the first can always be taken as (0, 0) and the second as $(x,0)$, which defines the x-AXIS. The remaining $n-2$ points need two coordinates each. However, the total number of distances is

$$\binom{n}{2}=\frac{n!}{2!(n-2)!}=\frac{1}{2}n(n-1), \tag{6}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The distances between $n>1$ points are therefore subject to m relationships, where

$$m\equiv\frac{1}{2}n(n-1)-(2n-3)=\frac{1}{2}(n-2)(n-3). \tag{7}$$

For $n=1, 2, ...$, this gives 0, 0, 0, 1, 3, 6, 10, 15, 21, 28, ... (Sloane's A000217) relationships, and the number of relationships between n points is the TRIANGULAR NUMBER T_{n-3}.

Although there are no relationships for $n=2$ and $n=3$ points, for $n=4$ (a QUADRILATERAL), there is one (Weinberg 1972):

$$\begin{aligned}0=&d_{12}^4d_{34}^2+d_{13}^4d_{24}^2+d_{14}^4d_{23}^2+d_{23}^4d_{14}^2+d_{24}^4d_{13}^2+d_{34}^4d_{12}^2\\&+d_{12}^2d_{23}^2d_{31}^2+d_{12}^2d_{24}^2d_{41}^2+d_{13}^2d_{34}^2d_{41}^2\\&+d_{23}^2d_{34}^2d_{42}^2-d_{12}^2d_{23}^2d_{34}^2-d_{13}^2d_{32}^2d_{24}^2\\&-d_{12}^2d_{24}^2d_{43}^2-d_{14}^2d_{42}^2d_{23}^2-d_{13}^2d_{34}^2d_{42}^2\\&-d_{14}^2d_{43}^2d_{32}^2-d_{23}^2d_{31}^2d_{14}^2-d_{21}^2d_{13}^2d_{34}^2\\&-d_{24}^2d_{41}^2d_{13}^2-d_{21}^2d_{14}^2d_{43}^2-d_{31}^2d_{12}^2d_{24}^2\\&-d_{32}^2d_{21}^2d_{14}^2.\end{aligned} \tag{8}$$

This equation can be derived by writing

$$d_{ij}\equiv\sqrt{(x_i-x_j)^2+(y_i-y_j)^2} \tag{9}$$

and eliminating x_i and y_j from the equations for d_{12}, d_{13}, d_{14}, d_{23}, d_{24}, and d_{34}.. This results in a CAYLEY-MENGER DETERMINANT

$$0=\begin{vmatrix}0&1&1&1&1\\1&0&d_{12}^2&d_{13}^2&d_{14}^2\\1&d_{21}^2&0&d_{23}^2&d_{24}^2\\1&d_{31}^2&d_{32}^2&0&d_{34}^2\\1&d_{41}^2&d_{42}^2&d_{43}^2&0\end{vmatrix}, \tag{10}$$

as observed by Uspensky (1948, p. 256).

Distance Graph

Let D be a set of positive numbers containing 1, then the D-distance graph $X(D)$ on a nonempty subset X of Euclidean space is the GRAPH with vertex set X and edge set $\{(x,y):d(x,y)\in D\}$, where $d(x,y)$ is the Euclidean distance between vertices x and y.

Distinct Prime Factors

The number of distinct prime factors of a number n is denoted (n). The first few values for $n = 1, 2, \ldots$ are 0, 1, 1, 1, 1, 2, 1, 1, 1, 2, 1, 2, 1, 2, 2, 1, 1, 2, 1, 2, ... (Sloane's A001221; Abramowitz and Stegun 1972, Kac 1959). This sequence is given by the inverse MÖBIUS TRANSFORM of $b_n = 1$ for n prime and $b_n = 0$ for n (Sloane and Plouffe 1995, p. 22).

The first few values of the SUMMATORY FUNCTION

$$\sum_{k=2}^{n} \omega(k)$$

are 1, 2, 3, 4, 6, 7, 8, 9, 11, 12, 14, 15, 17, 19, 20, 21, ... (Sloane's A013939), and the asymptotic value is

$$\sum_{k=2}^{n} \omega(k) = n \ln \ln n + B_1 n + o(n),$$

where B_1 is MERTENS CONSTANT. In addition,

$$\sum_{k=2}^{n} [\omega(k)]^2 = n(\ln \ln n)^2 + O(\ln \ln n).$$

The numbers consisting only of distinct prime factors are precisely the SQUAREFREE numbers.

Distribution (Generalized Function)

The class of all regular sequences of PARTICULARLY WELL-BEHAVED FUNCTIONS equivalent to a given regular sequence. A distribution is sometimes also called a "generalized function" or "ideal function." As its name implies, a generalized function is a generalization of the concept of a FUNCTION. For example, in physics, a baseball being hit by a bat encounters a force from the bat, as a function of time. Since the transfer of momentum from the bat is modeled as taking place at an instant, the force is not actually a function. Instead, it is a multiple of the DELTA FUNCTION. The set of distributions contains functions (LOCALLY INTEGRABLE) and RADON MEASURES. Note that the term "distribution" is closely related to STATISTICAL DISTRIBUTIONS.

Generalized functions are defined as continuous linear FUNCTIONALS over a SPACE of infinitely differentiable functions such that all continuous functions have derivatives which are themselves generalized functions. The most commonly encountered generalized function is the DELTA FUNCTION. Vladimirov (1984) contains a nice treatment of distributions from a physicist's point of view, while the multi-volume work by Gel'fand and Shilov (1977) is a classic and rigorous treatment of the field.

While it is possible to add distributions, it is not possible to multiply distributions when they have coinciding singular support. Despite this, it is possible to take the DERIVATIVE of a distribution, to get another distribution. Consequently, they may satisfy a linear PARTIAL DIFFERENTIAL EQUATION, in which case the distribution is called a weak solution. For example, given any locally integrable function f it makes sense to ask for solutions u of POISSON'S EQUATION

$$\nabla^2 u = f \qquad (1)$$

by only requiring the equation to hold in the sense of distributions, that is, both sides are the same distribution. The definitions of the derivatives of a distribution $p(x)$ are given by

$$\int_{-\infty}^{\infty} p'(x) f(x) dx = -\int_{\infty}^{\infty} p(x) f'(x) dx \qquad (2)$$

$$\int_{-\infty}^{\infty} p^{(n)}(x) f(x) dx = (-1)^n \int_{-\infty}^{\infty} p(x) f^{(n)}(x) dx. \qquad (3)$$

Distributions also differ from functions because they are COVARIANT, that is, they push forward. Given a SMOOTH FUNCTION $\alpha : \Omega_1 \to \Omega_2$, a distribution T on Ω_1

pushes forward to a distribution on Ω_2. In contrast, a REAL FUNCTION f on Ω_2. pulls back to a function on Ω_1, namely $f(\alpha(x))$.

Distributions are, by definition, the dual to the SMOOTH FUNCTIONS of COMPACT SUPPORT, with a particular TOPOLOGY. For example, the DELTA FUNCTION δ is the LINEAR FUNCTIONAL $\delta(f)=f(0)$. The distribution corresponding to a function g is

$$T_g(f)=\int_\Omega fg, \tag{4}$$

and the distribution corresponding to a MEASURE μ is

$$T_\mu(f)=\int_\Omega f d\mu. \tag{5}$$

The PUSHFORWARD MAP of a distribution T along α is defined by

$$\alpha_* T(f)=T(f\circ\alpha), \tag{6}$$

and the derivative of T is defined by $DT(f)=T(D^* f)$ where D^* is the FORMAL ADJOINT of D. For example, the first derivative of the DELTA FUNCTION is given by

$$\frac{d}{dx}[\delta(f)]=-\left.\frac{df}{dx}\right|_{x=0}. \tag{7}$$

As is the case for any function space, the topology determines which LINEAR FUNCTIONALS are continuous, that is, are in the DUAL SPACE. The topology is defined by the family of SEMINORMS,

$$N_{K,\alpha}(f)=\sup_k \|D^\alpha f\|, \tag{8}$$

where sup denotes the SUPREMUM. It agrees with the C-INFINITY TOPOLOGY on compact subsets. In this topology, a sequence converges, $f_n \to f$, IFF there is a compact set K such that all f_n are supported in K and every derivative $D^\alpha f_n$ converges uniformly to $D^\alpha f$ in K. Therefore, the constant function 1 is a distribution, because if $f_n \to f$, then

$$T_1(f_n)=\int_K f_n \to \int_K f=T_1(f). \tag{9}$$

Distribution (Statistical)

STATISTICAL DISTRIBUTION

Distribution Function

The distribution function $D(x)$, sometimes also called the PROBABILITY DISTRIBUTION FUNCTION, describes the probability that a trial X takes on a value less than or equal to a number x. The distribution function is therefore related to a continuous PROBABILITY DENSITY FUNCTION $P(x)$ by

$$D(x)=P(X\le x)\equiv\int_{-\infty}^{x} P(x')dx', \tag{1}$$

so $P(x)$ (when it exists) is simply the derivative of the distribution function

$$P(x)=D'(x)=[P(x')]_{-\infty}^{x}=P(x)-P(-\infty). \tag{2}$$

Similarly, the distribution function is related to a discrete probability $P(x)$ by

$$D(x)=P(X\le x)=\sum_{X\le x} P(x). \tag{3}$$

In general, there exist distributions which are neither continuous nor discrete.

A JOINT DISTRIBUTION FUNCTION can be defined if outcomes are dependent on two parameters:

$$D(x,y) \equiv P(X \leq x, Y \leq y) \tag{4}$$

$$D_x(x) \equiv D(x, \infty) \tag{5}$$

$$D_y(y) \equiv D(\infty, y). \tag{6}$$

Similarly, a multiple distribution function can be defined if outcomes depend on n parameters:

$$D(a_1, ..., a_n) \equiv P(x_1 \leq a_1, ..., x_n \leq a_n). \tag{7}$$

Given a continuous $P(x)$, assume you wish to generate numbers distributed as $P(x)$ using a random number generator. If the random number generator yields a uniformly distributed value y_i in $[0,1]$ for each trial i, then compute

$$D(x) \equiv \int^x P(x')dx'. \tag{8}$$

The FORMULA connecting y_i with a variable distributed as $P(x)$ is then

$$x_i = D^{-1}(y_i), \tag{9}$$

where $D^{-i}(x)$ is the inverse function of $D(x)$,. For example, if $P(x)$ were a GAUSSIAN DISTRIBUTION so that

$$D(x) = \frac{1}{2}\left[1 + \text{erf}\left(\frac{x\text{-}\mu}{\sigma\sqrt{2}}\right)\right], \tag{10}$$

then

$$x_i = \sigma\sqrt{2}\,\text{erf}^{-1}(2y_i - 1) + \mu. \tag{11}$$

A distribution with constant VARIANCE of y for all values of x is known as a HOMOSCEDASTIC distribution. The method of finding the value at which the distribution is a maximum is known as the MAXIMUM LIKELIHOOD method.

Distribution Parameter

The distribution parameter of a NONCYLINDRICAL RULED SURFACE parameterized by

$$\mathbf{x}(u,v) = \sigma(u) + v\delta(u), \tag{1}$$

where σ is the STRICTION CURVE and δ the DIRECTOR CURVE, is the function p defined by

$$p = \frac{\det(\sigma'\delta\delta')}{\delta'.\delta'}. \tag{2}$$

The GAUSSIAN CURVATURE of a RULED SURFACE is given in terms of its distribution parameter by

$$K = -\frac{[p(u)]^2}{\left\{[p(u)]^2 + v^2\right\}^2}. \tag{3}$$

Ditrigonal Dodecahedron

DITRIGONAL DODECADODECAHEDRON

Divergence

The divergence of a VECTOR FIELD **F** is given by

$$div(\mathbf{F}) \equiv \nabla\cdot\mathbf{F} \equiv \lim_{V\to 0} \frac{\oint_s \mathbf{F}\cdot d\mathbf{a}}{V}. \quad (1)$$

Define

$$\mathbf{F} \equiv F_1\hat{\mathbf{u}}_1 + F_2\hat{\mathbf{u}}_2 + F_3\hat{\mathbf{u}}_3. \quad (2)$$

Then in arbitrary orthogonal CURVILINEAR COORDINATES,

$$\mathrm{div}(F) \equiv \nabla\cdot\mathbf{F} \equiv \frac{1}{h_1h_2h_3}\left[\frac{\partial}{\partial u_1}(h_2h_3F_1) + \frac{\partial}{\partial u_2}(h_3h_1F_2) + \frac{\partial}{\partial u_3}(h_1h_2F_3)\right]. \quad (3)$$

If $\nabla\cdot\mathbf{F}=0$, then the field is said to be a DIVERGENCELESS FIELD. For divergence in individual coordinate systems, see CURVILINEAR COORDINATES.

$$\nabla\cdot\frac{\mathbf{Ax}}{|\mathbf{x}|} = \frac{\mathrm{Tr}(\mathbf{A})}{|\mathbf{x}|} - \frac{\mathbf{x}^{\mathrm{T}}(\mathbf{Ax})}{|\mathbf{x}|^3}. \quad (4)$$

The divergence of a TENSOR A is

$$\nabla\cdot A \equiv A^{\alpha}_{i\alpha} \quad (5)$$

$$= A^k_{,k} + \Gamma^k_{jk}A^j, \quad (6)$$

$$= \frac{1}{g^{1/2}}\left(g^{1/2}A^k\right), k \quad (7)$$

where $A^{\alpha}_{i\alpha}$ is the COVARIANT DERIVATIVE, $A^k_{,k}$ is the COMMA DERIVATIVE, g_{ij} is the METRIC TENSOR, and $g = \det(g_{ij})$, (Arfken 1985, p. 165). Expanding the terms gives

$$A^{\alpha}_{;\alpha} = A^{\alpha}_{,\alpha} + \left(\Gamma^{\alpha}_{\alpha\alpha}A^{\alpha} + \Gamma^{\alpha}_{\beta\alpha}A^{\beta} + \Gamma^{\alpha}_{\gamma\alpha}A^{\gamma}\right)$$
$$+ A^{\beta}_{,\beta} + \left(\Gamma^{\beta}_{\alpha\beta}A^{\alpha} + \Gamma^{\beta}_{\beta\beta}A^{\beta} + \Gamma^{\beta}_{\gamma\beta}A^{\gamma}\right)$$
$$+ A^{\gamma}_{,\gamma} + \left(\Gamma^{\gamma}_{\alpha\gamma}A^{\alpha} + \Gamma^{\gamma}_{\beta\gamma}A^{\beta} + \Gamma^{\gamma}_{\gamma\gamma}A^{\gamma}\right). \quad (8)$$

See also COMMA DERIVATIVE, COVARIANT DERIVATIVE, CURL, CURL THEOREM, DIVERGENCE THEOREM, GRADIENT, GREEN'S THEOREM, VECTOR DERIVATIVE

References

Arfken, G. "Divergence, $\nabla\cdot$." §1.7 in *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 37–2, 1985.

Divergence Tests

If

$$\lim_{k\to\infty} u_k \neq 0,$$

then the series $\{u_n\}$ diverges.

See also CONVERGENCE TESTS, CONVERGENT SERIES, DINI'S TEST, SERIES

Divergence Theorem

A.k.a. GAUSS'S THEOREM. Let V be a region in space with boundary ∂V. Then

$$\int_V (\nabla\cdot\mathbf{F})\mathrm{d}V = \int_{\partial V} \mathbf{F}\cdot d\mathbf{a}. \quad (1)$$

Let S be a region in the plane with boundary ∂S.

$$\int_S \nabla.\mathbf{F}\mathrm{d}A = \int_{\partial S} \mathbf{F}.\mathbf{n}ds. \quad (2)$$

If the VECTOR FIELD **F** satisfies certain constraints,

simplified forms can be used. If $\mathbf{F}(x,y,z) = v(x,y,z)\mathbf{c}$ where $\mathbf{c}$ is a constant vector $\neq 0$, then

$$\int_S \mathbf{F}.d\mathbf{a} = \mathbf{c}\cdot\int_S v d\mathbf{a}. \quad (3)$$

But

$$\nabla\cdot(f\mathbf{v}) = (\nabla f)\cdot\mathbf{v} + f(\nabla\cdot\mathbf{v}), \quad (4)$$

so

$$\int_V \nabla\cdot(\mathbf{c}v)\mathrm{d}V = \mathbf{c}\cdot\int_V (\nabla v + v\nabla\cdot\mathbf{c})\mathrm{d}V = \mathbf{c}.\int_V \nabla v\mathrm{d}V \quad (5)$$

$$\mathbf{c}\cdot\left(\int_S v d\mathbf{a} - \int_V \nabla v\mathrm{d}V\right) = 0. \quad (6)$$

But $\mathbf{c} \neq 0$, and $\mathbf{c}.\mathbf{f}(v)$ must vary with v so that $\mathbf{c}.\mathbf{f}(v)$ cannot always equal zero. Therefore,

$$\int_S v\mathrm{d}\mathbf{a} = \int_V \nabla v\mathrm{d}V. \quad (7)$$

If $\mathbf{F}(x,y,z) = \mathbf{c}\times P(x,y,z)$, where $\mathbf{c}$ is a constant vector $\neq 0$, then

$$\int_S d\mathbf{a}\times\mathbf{P}\int_V \nabla\times\mathbf{P}\mathrm{d}V. \quad (8)$$

See also Curl Theorem, Gradient, Green's Theorem

References

Arfken, G. "Gauss's Theorem." §1.11 in *Mathematical Methods for Physicists, 3rd ed.* Orlando, FL: Academic Press, pp. 57–1, 1985.

Divergenceless Field

A divergenceless field, also called a solenoidal field, is a field for which $\nabla\cdot\mathbf{F} \equiv 0$. Therefore, there exists a $\mathbf{G}$ such that $\mathbf{F} = \nabla\times\mathbf{G}$. Furthermore, $\mathbf{F}$ can be written as

$$\mathbf{F} = \nabla\times(T\mathbf{r}) + \nabla^2(S\mathbf{r}) \equiv \mathbf{T} + \mathbf{S}, \quad (1)$$

where

$$\mathbf{T} \equiv \nabla\times(T\mathbf{r}) = -\mathbf{r}\times(\nabla T) \quad (2)$$

$$\mathbf{S} \equiv \nabla^2(S\mathbf{r}) = \nabla\left[\frac{\partial}{\partial r}(rS)\right] - \mathbf{r}\nabla^2 S. \quad (3)$$

Following Lamb, $\mathbf{T}$ and $\mathbf{S}$ are called toroidal field and poloidal field.

See also Beltrami Field, Irrotational Field, Poloidal Field, Solenoidal Field, Toroidal Field

Divergent Sequence

A divergent sequence is a sequence for which the limit exists but is not convergent.

See also Convergent Sequence, Divergent Series

Divergent Series

A series which is not convergent. Series may diverge by marching off to infinity or by oscillating. Divergent series have some curious properties. For example, rearranging the terms of $1-1+1-1+1-\cdots$ gives both $(1-1)+(1-1)+(1-1)+\cdots = 0$ and $1-(1-1)-(1-1)+\cdots = 1$..

The Riemann series theorem states that, by a suitable rearrangement of terms, a conditionally convergent series may be made to converge to any desired value, or to diverge.

No less an authority than N. H. Abel wrote "The divergent series are the invention of the devil, and it is a shame to base on them any demonstration whatsoever" (Gardner 1984, p. 171; Hoffman 1998, p. 218). However, divergent series *can* actually be "summed" rigorously by using extensions to the usual summation rules (e.g., so-called Abel and Cesàro sums). For example, the divergent series $1-1+1-1+1-\cdots$ has both Abel and Cesàro sums of 1/2.

See also Absolute Convergence, Conditional Convergence, Convergent Series, Divergent Sequence

Diversity Condition

For any group of k men out of N, there must be at least k jobs for which they are collectively qualified.

Divide

To divide is to perform the operation of division, i.e., to see how many times a divisor d goes into another number n. n divided by d is written n/d or $n \div d$. The result need not be an integer, but if it is, some additional terminology is used. $d|n$ is read "d divides n" and means that d is a divisor of n. In this case, n is said to be divisible by d. Clearly, $1|n$ and $n|n$. By convention, $n|0$ for every n except 0 (Hardy and Wright 1979). The "divisibility" relation satisfies

$$b|a \quad for \quad c|b \Rightarrow c|a$$

$$b|a \Rightarrow bc|ac$$

$$c|a \quad and \quad c|b \quad \Rightarrow c|(ma+nb),$$

where the symbol $\Rightarrow$ means IMPLIES.

$d' \nmid n$ is read "d' does not divide n" and means that d' is not a DIVISOR of n. $a^k \| b$ means a^k divides b exactly. If n and d are RELATIVELY PRIME, the notation $(n,d)=1$ or sometimes $n \perp d$ is used.

Divided Difference

The divided difference $f[x_1, x_2, ..., x_n]$ on n points x_1, x_2, ..., x_n of a function $f(x)$ is defined by $f[x_1] \equiv f(x_1)$ and

$$f[x_1, x_2, ..., x_n] = \frac{f[x_1, ..., x_n] - f[x_2, ..., x_n]}{x_1 - x_n} \tag{1}$$

for $n \geq 2$. The first few differences are

$$[x_0, x_1] = \frac{f_0 - f_1}{x_0 - x_1} \tag{2}$$

$$[x_0, x_1, x_2] = \frac{[x_0, x_1] - [x_1, x_2]}{x_0 - x_2} \tag{3}$$

$$[x_0, x_1, ..., x_n] = \frac{[x_0, ..., x_{n-1}] - [x_1, ..., x_n]}{x_0 - x_n}. \tag{4}$$

Defining

$$\pi_n(x) \equiv (x-x_0)(x-x_1)\cdots(x-x_n) \tag{5}$$

and taking the DERIVATIVE

$$\pi_n'(x_k) = (x_k - x_0)...(x_k - x_{k-1})...(x_k - x_n) \tag{6}$$

gives the identity

$$[x_0, x_1, ..., x_n] = \sum_{k=0}^{n} \frac{f_k}{\pi_n'(x_k)}. \tag{7}$$

Consider the following question: does the property

$$f[x_1, x_2, ..., x_n] = h(x_1 + x_2 + ... + x_n) \tag{8}$$

for $n \geq 2$ and $h(x)$ a given function guarantee that $f(x)$ is a POLYNOMIAL of degree $\leq n$? Aczél (1985) showed that the answer is "yes" for $n=2$, and Bailey (1992) showed it to be true for $n=3$ with differentiable $f(x)$. Schwaiger (1994) and Andersen (1996) subsequently showed the answer to be "yes" for all $n \geq 3$ with restrictions on $f(x)$ or $h(x)$.

Divisibility Tests

Write a positive decimal integer a out digit by digit in the form $a_n \cdots a_3 a_2 a_1 a_0$. The following rules then determine if a is DIVISIBLE by another number by examining the CONGRUENCE properties of its digits. In CONGRUENCE notation, $n \equiv k (\text{mod} m)$ means that the remainder when n is divided by a modulus m is k. (Note that it is always true that $10^0 = 1 \equiv 1$ for any base.)

1. All integers are DIVISIBLE by 1.
2. $10^1 \equiv 0 (\text{mod} 2)$, so $10^n \equiv 0 (\text{mod} 2)$ for $n \geq 1$. Therefore, if the last digit a_0 is DIVISIBLE by 2 (i.e., is EVEN), then so is a.
3. $10^0 \equiv 1$, $10^1 \equiv 1$, $10^2 \equiv 1$, ..., $10^n \equiv 1$ (mod 3). Therefore, if $\Sigma_{i=0}^{n} a_j$ is DIVISIBLE by 3, so is a (Wells 1986, p. 48).
4. $10^1 \equiv 2$, $10^2 \equiv 0$, ...$10^n \equiv 0$ (mod 4). So if the last two digits are DIVISIBLE by 4, more specifically if $r \equiv a_0 + 2a_1$ is, then so is a.
5. $10^1 \equiv 0 (\text{mod} 5)$, so $10^n \equiv 0 (\text{mod} 5)$ for $n \geq 1$. Therefore, if the last digit a_0 is DIVISIBLE by 5 (i.e., is 5 or 0), then so is a.
6. $10^1 \equiv -2$, $10^2 \equiv -2$, ..., $10^n \equiv -2$ (mod 6). Therefore, if $r \equiv a_0 - 2\Sigma_{i=1}^{n} a_i$ is DIVISIBLE by 6, so is a. A

simpler rule states that if a is DIVISIBLE by 3 and is EVEN, then a is also DIVISIBLE by 6.

7a. $10^1 \equiv 3$, $10^2 \equiv 2$, $10^3 \equiv -1$, $10^4 \equiv -3$, $10^5 \equiv -2$, $10^6 \equiv 1 \pmod 7$, and the sequence then repeats. Therefore, if $r \equiv (a_0 + 3a_1 + 2a_2 - a_3 - 3a_4 - 2a_5) + (a_6 + 3a_7 + \cdots) + \cdots$ is DIVISIBLE by 7, so is a.

7b. An alternate test proceeds by multiplying a_n by 3 and adding to a_{n-1}, then repeating the procedure up through a_0. The final number can then, of course, be further reduced using the same procedure. If the result is divisible by 7, then so is the original number (Wells 1986, p. 70).

7c. A third test multiplies a_0 by 5 and adds it to a_1, proceeding up through a_n. The final number can then, of course, be further reduced using the same procedure. If the result is divisible by 7, then so is the original number (Wells 1986, p. 70).

8. $10^1 \equiv 2$, $10^2 \equiv 4$, $10^3 \equiv 0$, ..., $10^n \equiv 0 \pmod 8$. Therefore, if the last three digits are DIVISIBLE by 8, more specifically if $r \equiv a_0 + 2a_1 + 4a_2$ is, then so is a (Wells 1986, p. 72).

9. $10^0 \equiv 1$, $10^1 \equiv 1$, $10^2 \equiv 1$, ..., $10^n \equiv 1 \pmod 9$. Therefore, if $\Sigma_{i=0}^{n} a_i$ is DIVISIBLE by 9, so is a (Wells 1986, p. 74).

10. $10^1 \equiv 0 \pmod{10}$, so if the last digit is 0, then a is DIVISIBLE by 10.

11. $10^1 \equiv -1$, $10^2 \equiv 1$, $10^3 \equiv -1$, $10^4 \equiv 1$, ... (mod 11). Therefore, if $r \equiv a_0 - a_1 + a_2 - a_3 + \cdots$ is DIVISIBLE by 11, then so is a.

12. $10^1 \equiv -2$, $10^2 \equiv 4$, $10^3 \equiv 4$, ... (mod 12). Therefore, if $r \equiv a_0 - 2a_1 + 4(a_2 + a_3 + \cdots)$ is DIVISIBLE by 12, then so is a. Divisibility by 12 can also be checked by seeing if a is DIVISIBLE by 3 and 4.

13. $10^1 \equiv -3$, $10^2 \equiv -4$, $10^3 \equiv -1$, $10^4 \equiv 3$, $10^5 \equiv 4$, $10^6 \equiv 1 \pmod{13}$, and the pattern repeats. Therefore, if $r \equiv (a_0 - 3a_1 - 4a_2 - a_3 + 3a_4 + 4a_5) + (a_6 - 3a_7 + \ldots) + \ldots$ is DIVISIBLE by 13, so is a.

For additional tests for 13, see Gardner (1991).

Divisible

A number n is said to be divisible by d if d is a DIVISOR of n.

The product of any n consecutive integers is divisible by $n!$. The sum of any n consecutive integers is divisible by n if n is ODD, and by $n/2$ if n is EVEN.

Division

Taking the RATIO x/y of two numbers x and y, also written $x \div y$. Here, x is called the DIVIDEND, y is called the DIVISOR, and x/y is called a QUOTIENT. The symbol "/" is called a SOLIDUS (or DIAGONAL), and the symbol "÷" is called the OBELUS. If left unevaluated, x/y is called a FRACTION, with x known as the NUMERATOR and y known as the DENOMINATOR.

Division in which the fractional (remainder) is discarded is called INTEGER DIVISION, and is sometimes denoted using a backslash, \.

Division is the inverse operation of MULTIPLICATION, so that if

$$a \times b = c,$$

then a can be recovered as

$$a = c \div b$$

as long as $b \neq 0$. In general, DIVISION BY ZERO is not defined since the ability to "invert" $a \times b = c$ to recover a breaks down if $b = 0$ (in which case c is always 0, independent of a).

Cutting or separating an object into two or more parts is also called division.

See also ADDITION, COMPLEX DIVISION, CUTTING, DENOMINATOR, DIVIDE, DIVIDEND, DIVISION BY ZERO, DIVISOR, INTEGER DIVISION, LONG DIVISION, MULTIPLICATION, NUMERATOR, OBELUS, ODDS, PLANE DIVISION BY LINES, QUOTIENT, RATIO, SKELETON DIVISION, SOLIDUS, SPACE DIVISION BY SPHERES, SUBTRACTION, TRIAL DIVISION, VECTOR DIVISION

Division Algebra

A division algebra, also called a "division ring" or "skew field," is a RING in which every NONZERO element has a multiplicative inverse, but multiplication is not COMMUTATIVE. In French, the term "corps non commutatif" is used to mean division algebra, while "corps" alone means FIELD.

Explicitly, a division algebra is a set together with two BINARY OPERATORS $S(+,*)$ satisfying the following conditions:

1. Additive associativity: For all $a, b, c \in S$, $(a+b)+c = a+(b+c)$,
2. Additive commutativity: For all $a, b \in S$, $a+b = b+a$,
3. Additive identity: There exists an element $0 \in S$ such that for all $a \in S$, $0+a = a+0 = a$,
4. Additive inverse: For every $a \in S$ there exists an element $-a \in S$ such that $a = (-a) = (-a)+a = 0$,
5. Multiplicative associativity: For all $a, b, c \in S$, $(a*b)*c = a*(b*c)$,
6. Multiplicative identity: There exists an element $1 \in S$ not equal to 0 such that for all $a \in S$, $1*a = a*1 = a$,
7. Multiplicative inverse: For every $a \in S$ not equal to 0, there exists $a^{-1} \in S$ such that $a*a^{-1} = a^{-1}*a = 1$,
8. Left and right distributivity: For all $a, b, c \in S$, $a*(b+c) = (a*b)+(a*c)$ and $(b+c)*a = (b*a)+(c*a)$.

Thus a division algebra $(S, +, *)$ is a UNIT RING for which $(S - \{0\}, *)$ is a GROUP. A division algebra must contain at least two elements. A COMMUTATIVE division algebra is called a FIELD.

In 1878 and 1880, Frobenius and Peirce proved that the only associative REAL division algebras are REAL NUMBERS, COMPLEX NUMBERS, and QUATERNIONS (Mishchenko and Solovyov 2000). The CAYLEY ALGEBRA is the only NONASSOCIATIVE DIVISION ALGEBRA. Hurwitz (1898) proved that the ALGEBRAS of REAL NUMBERS, COMPLEX NUMBERS, QUATERNIONS, and CAYLEY NUMBERS are the only ones where multiplication by unit "vectors" is distance-preserving.

Adams (1956) proved that n-dimensional vectors form an ALGEBRA in which division (except by 0) is always possible only for $n = 1$, 2, 4, and 8. Bott and Milnor (1958) proved that the only finite dimensional real division algebras occur for dimensions $n = 1$, 2, 4, and 8. Each gives rise to an ALGEBRA with particularly useful physical applications (which, however, is not itself necessarily nonassociative), and these four cases correspond to REAL NUMBERS, COMPLEX NUMBERS, QUATERNIONS, and CAYLEY NUMBERS, respectively.

Division by Zero

Division by zero is the operation of taking the QUOTIENT of any number x and 0, i.e., $x/0$. The uniqueness of DIVISION breaks down when dividing by zero, since the product $0 \cdot y = 0$ is the same for any y, so y cannot be recovered by inverting the process of MULTIPLICATION. 0 is the only number with this property and, as a result, division by zero is UNDEFINED for REAL NUMBERS and can produce a fatal condition called a "division by zero error" in computer programs.

There are, however, contexts in which division by zero can be considered as defined. For example, division by zero $z/0$ for $z \in \mathbb{C}^* \neq 0$ in the EXTENDED COMPLEX PLANE C* is defined to be a quantity known as COMPLEX INFINITY. This definition expresses the fact that, for $z \neq 0$, $\lim_{w \to 0} z/w = \infty$ (i.e., COMPLEX INFINITY). However, even though the formal statement $1/0 = \infty$ is permitted in C*, note that this does *not* mean that $1 = 0 \cdot \infty$. Zero does not have a multiplicative inverse under any circumstances.

Although division by zero is not defined for reals, LIMITS involving division by a real quantity x which *approaches* zero may be in fact be WELL DEFINED. For example,

$$\lim_{x \to 0} \frac{\sin x}{x} = 1.$$

Of course, such limits may also approach INFINITY,

$$\lim_{x \to 0^+} \frac{1}{x} = \infty.$$

See also C*, COMPLEX INFINITY, COMPLEX NUMBER, DIVISION, EXTENDED COMPLEX PLANE, FALLACY, FIELD, LIMIT REAL NUMBER, RING, ZERO

Division Lemma

When ac is DIVISIBLE by a number b that is RELATIVELY PRIME to a, then c must be DIVISIBLE by b.

Division Ring

DIVISION ALGEBRA

Divisor

A divisor of a number N is a number d which DIVIDES N, also called a FACTOR. The total number of divisors for a given number N can be found as follows. Write a number in terms of its PRIME FACTORIZATION

$$N = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_r^{\alpha_r}. \tag{1}$$

For any divisor d of N, $N = dd'$ where

$$d = p_1^{\delta_1} p_2^{\delta_2} \cdots p_r^{\delta_r}, \tag{2}$$

so

$$d' = p_1^{\alpha_1 - \delta_1} p_2^{\alpha_2 - \delta_2} \cdots p_r^{\alpha_r - \delta_r}. \tag{3}$$

Now, $\delta_1 = 0, 1, \ldots, \alpha_1$, so there are $\alpha_1 + 1$ possible values. Similarly, for δ_n, there are $\alpha_n + 1$ possible values, so the total number of divisors $v(N)$ of N is given by

$$\nu(N) = \prod_{n=1}^{r} (\alpha_n + 1). \tag{4}$$

The function $\nu(N)$ is also sometimes denoted $d(N)$ or $\sigma_0(N)$. The product of divisors can be found by writing the number N in terms of all possible products

$$N = \begin{cases} d^{(1)} d'^{(1)} \\ \vdots \\ d^{(\nu)} d'^{(\nu)} \end{cases}, \tag{5}$$

so

$$N^{\nu(N)} = \left[d^{(1)} \cdots d^{(\nu)}\right]\left[d'^{(1)} d'^{(\nu)}\right]$$
$$= \prod_{i=1}^{\nu} d_i \prod_{i=1}^{\nu} d_i' = \left(\prod d\right)^2, \tag{6}$$

and

$$\prod d = N^{\nu(N)/2}. \tag{7}$$

The GEOMETRIC MEAN of divisors is

$$G \equiv \left(\prod d\right)^{1/\nu(N)} = \left[N^{\nu(n)/2}\right]^{1/\nu(N)} = \sqrt{N}. \tag{8}$$

The ARITHMETIC MEAN is

$$A(N) \equiv \frac{\sigma(N)}{\nu(N)}. \tag{9}$$

The HARMONIC MEAN is

$$\frac{1}{H} \equiv \frac{1}{N}\left(\sum \frac{1}{d}\right). \tag{10}$$

But $N = dd'$, so $1/d = d'/N$ and

$$\sum \frac{1}{d} = \frac{1}{N} \sum d' = \frac{1}{N} \sum d = \frac{\sigma(N)}{N}, \tag{11}$$

and we have

$$\frac{1}{H(N)} = \frac{1}{\nu(N)} \frac{\sigma(N)}{N} = \frac{A(N)}{N} \tag{12}$$

$$N = A(N)H(N). \tag{13}$$

Given three INTEGERS chosen at random, the probability that no common factor will divide them all is

$$[\zeta(3)]^{-1} \approx 1.20206^{-1} \approx 0.831907, \tag{14}$$

where $\zeta(3)$ is APÉRY'S CONSTANT.

The smallest numbers having exactly 0, 1, 2, ... divisors (other than 1) are 1, 2, 4, 6, 16, 12, 64, 24, 36, ... (Sloane's A005179).

Let $f(n)$ be the number of elements in the greatest subset of $[1, n]$ such that none of its elements are divisible by two others. For n sufficiently large,

$$0.6725 \ldots \le \frac{f(n)}{n} \le 0.673 \ldots \tag{15}$$

(Le Lionnais 1983, Lebensold 1976/1977).

Divisor Function

$\sigma_k(n)$ for n an integer is defined as the sum of the kth POWERS of the DIVISORS of n. As an illustrative example, consider the number 140, which has DIVISORS $d_i = 1, 2, 4, 5, 7, 10, 14, 20, 28, 35, 70$, and 140 (for a total of $N = 12$ of them). Therefore,

$$d(140) = \sigma_0(140) = N = 12 \tag{1}$$

$$\sigma(140) = \sigma_1(140) = \sum_{i=1}^{N} d_i = 336 \tag{2}$$

$$\sigma_2(140) = \sum_{i=1}^{N} d_i^2 = 27,300 \tag{3}$$

$$\sigma_3(140) = \sum_{i=1}^{N} d_i^3 = 3,164,112. \tag{4}$$

The divisor function can also be generalized to GAUSSIAN INTEGERS.

The function $\sigma_0(n)$ gives the total number of DIVISORS of n and is often denoted $d(n)$, $\nu(n)$, $\tau(n)$, or $\Omega(n)$. (Hardy and Wright 1979, pp. 354–55). The first few values of $\sigma_0(n)$ are 1, 2, 2, 3, 2, 4, 2, 4, 3, 4, 2, 6, ... (Sloane's A000005). These values can be found as the inverse MÖBIUS TRANSFORM of 1, 1, 1, ... (Sloane and Plouffe 1995, p. 22). Heath-Brown (1984) proved that $\sigma_0(n) = \sigma_0(n+1)$ infinitely often.

The function $\sigma_1(n)$ is equal to the sum of DIVISORS of n and is often denoted $\sigma(n)$. The first few values of $\sigma(n)$ are 1, 3, 4, 7, 6, 12, 8, 15, 13, 18, ... (Sloane's A000203). The first few values of $\sigma_2(n)$ are 1, 5, 10, 21, 26, 50, 50, 85, 91, 130, ... (Sloane's A001157). The first few values of $\sigma_3(n)$ are 1, 9, 28, 73, 126, 252, 344, 585, 757, 1134, ... (Sloane's A001158).

The sum of the DIVISORS of n excluding n itself (i.e., the PROPER DIVISORS of n) is called the RESTRICTED DIVISOR FUNCTION and is denoted $s(n)$. The first few values are 0, 1, 1, 3, 1, 6, 1, 7, 4, 8, 1, 16, ... (Sloane's A001065).

The sum of divisors $\sigma(N)$ can be found as follows. Let $N \equiv ab$ with $a \neq b$ and $(a, b) = 1$. For any divisor d of N, $d = a_i b_i$, where a_i is a divisor of a and b_i is a divisor of b. The divisors of a are 1, a_1, a_2, ..., and a. The divisors of b are 1, b_1, b_2, ..., b. The sums of the divisors are then

$$\sigma(a) = 1 + a_1 + a_2 + \ldots + a \tag{5}$$

$$\sigma(b) = 1 + b_1 + b_2 + \ldots + b. \tag{6}$$

For a given a_i,

$$a_i(1 + b_1 + b_2 + \ldots + b) = a_i\sigma(b). \tag{7}$$

Summing over all a_i,

$$(1 + a_1 + a_2 + \ldots + a)\sigma(b) = \sigma(a)\sigma(b), \tag{8}$$

so $\sigma(N) = \sigma(ab) = \sigma(a)\sigma(b)$. Splitting a and b into prime factors,

$$\sigma(N) = \sigma(p_1^{\alpha_1})\sigma(p_2^{\alpha_2})\ldots\sigma(p_r^{\alpha_r}). \tag{9}$$

For a prime POWER $p_i^{\alpha_i}$, the divisors are $1, p_i, p_i^2, \ldots, p_i^{\alpha_i}$, so

$$\sigma(p_i^{\alpha_i}) = 1 + p_i + p_i^2 + \ldots + p_i^{\alpha_i} = \frac{p_i^{\alpha_i+1} - 1}{p_i - 1}. \tag{10}$$

For N, therefore,

$$\sigma(N) = \prod_{i=1}^{r} \frac{p_i^{\alpha+1} - 1}{p_i - 1}. \tag{11}$$

For the special case of N a PRIME, (11) simplifies to

$$\sigma(p) = \frac{p^2 - 1}{p - 1} = p + 1. \tag{12}$$

For N a POWER of two, (11) simplifies to

$$\sigma(2^\alpha) = \frac{2^{\alpha+1} - 1}{2 - 1} = 2^{\alpha+1} - 1. \tag{13}$$

The identity (9) can be generalized to

$$\sigma_k(N) = \sigma_k(p_1^{\alpha_1})\sigma_k(p_2^{\alpha_2})\ldots\sigma_k(p_r^{\alpha_r}). \tag{14}$$

In general,

$$\sigma_k(n) \equiv \sum_{d|n} \mathrm{d}^k. \tag{15}$$

The $\sigma(n)$ function has the series expansion

$$\sigma(n) = \frac{1}{6}\pi^2 n \left[1 + \frac{(-1)^n}{2^2} + \frac{2\cos\left(\frac{2}{3}n\pi\right)}{3^2} + \frac{2\cos\left(\frac{1}{2}n\pi\right)}{4^2} + 2\left[\frac{\cos\left(\frac{2}{5}n\pi\right) + \cos\left(\frac{4}{5}n\pi\right)}{5^2 + \ldots}\right]\right] \tag{16}$$

(Hardy 1999). Ramanujan gave the beautiful formula

$$\sum_{n=1}^{\infty} \frac{\sigma_a(n)\sigma_b(n)}{n^s} = \frac{\zeta(s)\zeta(s-a)\zeta(s-b)\zeta(s-a-b)}{\zeta(2s-a-b)}, \quad (17)$$

where $\zeta(n)$ is the ZETA FUNCTION and $\Re[s], \Re[s-a], \Re[s-b], \Re[s-a-b] > 1$ (Wilson 1923), which was used by Ingham in a proof of the PRIME NUMBER THEOREM (Hardy 1999, pp. 59–0). This gives the special case

$$\sum_{n=1}^{\infty} \frac{[d(n)]^2}{n^s} = \frac{[\zeta(s)]^4}{\zeta(2s)} \quad (18)$$

(Hardy 1999, p. 59).

The divisor function also satisfies the INEQUALITY

$$\frac{\sigma(n)}{n \ln \ln n} \le e^{\gamma} + \frac{2(1-\sqrt{2}) + \gamma - \ln(4\pi)}{\sqrt{\ln n} \ln \ln n} + o\left(\frac{1}{\sqrt{\ln n}(\ln \ln n)^2}\right), \quad (19)$$

where γ is the EULER-MASCHERONI CONSTANT (Robin 1984, Erdos 1989).

Let a number n have prime factorization

$$n = \prod_{j=1}^{r} p_j^{\alpha_j}, \quad (20)$$

then

$$\sigma(n) = \prod_{j=1}^{r} \frac{p_j^{\alpha_j+1} - 1}{p_j - 1} \quad (21)$$

(Berndt 1985). GRONWALL'S THEOREM states that

$$\overline{\lim_{n\to\infty}} \frac{\sigma(n)}{n \ln \ln n} = e^{\gamma}, \quad (22)$$

where γ is the EULER-MASCHERONI CONSTANT. $\sigma(n)$ is a power of 2 IFF $n = 1$ or n is a product of distinct MERSENNE PRIMES (Sierpinski1958/59, Sivaramakrishnan 1989, Kaplansky 1999). The first few such n are 1, 3, 7, 21, 31, 93, 127, 217, 381, 651, 889, 2667, ... (Sloane's A046528), and the powers of 2 these correspond to are 0, 2, 3, 5, 5, 7, 7, 8, 9, 10, 10, 12, 12, 13, 14, ... (Sloane's A048947).

Curious identities derived using MODULAR FORM theory are given by

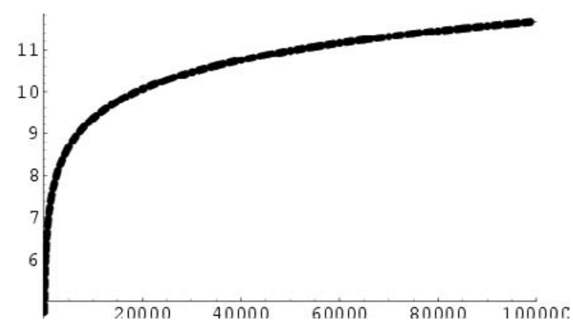
$$\sigma_3(n) - \sigma_7(n) + 120 \sum_{k=1}^{n-1} \sigma_3(k)\sigma_3(n-k) = 0 \quad (23)$$

$$-10\sigma_3(n) + 21\sigma_5(n) - 11\sigma_9(n) + 5040 \sum_{k=1}^{n-1} \sigma_3(k)\sigma_5(n-k) = 0 \quad (24)$$

(Apostol 1997, p. 140), together with

$$21\sigma_5(n) - 20\sigma_7(n) - \sigma_{13}(n) + 10080 \sum_{k=1}^{n-1} \sigma_5(n-k)\sigma_7(k) = 0 \quad (25)$$

$$-10\sigma_3(n) + 11\sigma_9(n) - \sigma_{13}(n) + 2640 \sum_{k=1}^{n-1} \sigma_3(n-k)\sigma_9(k) = 0 \quad (26)$$



$$-21\sigma_5(n) + 22\sigma_9(n) - \sigma_{13}(n) - 2904 \sum_{k=1}^{n-1} \sigma_9(n-k)\sigma_9(k) + 504 \sum_{k=1}^{n-1} \sigma_5(n-k)\sigma_{13}(k) = 0 \quad (27)$$

(M. Trott).

The divisor function is ODD IFF n is a SQUARE NUMBER or twice a SQUARE NUMBER. The divisor function satisfies the CONGRUENCE

$$n\sigma(n) \equiv 2 \pmod{\phi(n)}, \quad (28)$$

for all PRIMES and no COMPOSITE NUMBERS with the exception of 4, 6, and 22 (Subbarao 1974). $r(n)$ is PRIME whenever $\sigma(n)$ is (Honsberger 1991). Factorizations of $\sigma(p^a)$ for PRIME p are given by Sorli.

In 1838, Dirichlet showed that the average number of DIVISORS of all numbers from 1 to n is asymptotic to

$$\frac{\sum_{i=1}^{n} \sigma_0(i)}{n} \sim \ln n + 2\gamma - 1 \quad (29)$$

(Conway and Guy 1996; Hardy 1999, p. 55), as illustrated above, where the thin solid curve plots the actual values and the thick dashed curve plots the asymptotic function. This is related to the DIRICHLET DIVISOR PROBLEM, which seeks to find the "best" coefficient θ in

$$\sum_{k=1}^{n} \nu(k) = n \ln n + (2\gamma - 1)n + \mathcal{O}(n^{\theta}). \quad (30)$$

A more precise formula is given by

$$\sum_{k=2}^{n} \sigma_0(k) = n \ln \ln n + B_2 n + o(n), \quad (31)$$

where

$$B_2 = \gamma + \sum_{p \text{ prime}} \left[\ln(1 - p^{-1}) + \frac{1}{p-1} \right] \approx 1.034653 \quad (32)$$

(Hardy and Wright 1979, p. 355). The SUMMATORY FUNCTIONS for σ_a with $a > 1$ are

$$\sum_{k=1}^{n} \sigma_a(k) = \frac{\zeta(a+b)}{a+1} n^{a+1} + \mathcal{O}(n^a). \quad (33)$$

For $a = 1$,

$$\sum_{k=1}^{n} \sigma_1(k) = \frac{\pi^2}{12} n^2 + \mathcal{O}(n \ln n). \quad (34)$$

Divisor Product

Let $\pi(n)$ denote the product of the divisors of n including n itself. For $n = 1, 2, \ldots$, the first few values are 1, 2, 3, 8, 5, 36, 7, 64, 27, 100, 11, 1728, 13, 196, ... (Sloane's A007955). The following table gives values of n for which $\pi(n)$ is a Pth power. Lionnet (1879) considered the case $P = 1$.

P	Sloane	n
1	Sloane's A048943	1, 6, 8, 10, 14, 15, 16, 21, 22, 24, 26, ...
2	Sloane's A048944	1, 4, 8, 9, 12, 18, 20, 25, 27, 28, 32, ...
3	Sloane's A048945	1, 24, 30, 40, 42, 54, 56, 66, 70, 78, ...
4	Sloane's A048946	1, 16, 32, 48, 80, 81, 112, 144, 162, ...

Write the prime factorization of a number n,

$$n = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_r^{\alpha_r}.$$

Then the power of p_i occurring in $\pi(n)$ is

$$\frac{1}{2} a_i (a_1 + 1)(a_2 + 1) \cdots (a_r + 1)$$

(Kaplansky 1999). This allows rules for determining when $\pi(n)$ is a power of n to be determined, as

considered by Halcke (1719) and Lionnet (1879). Let p, q, and r be distinct primes, then the following table gives the conditions and first few n for which $\pi(n)$ is a given power P of n (Dickson 1952, Ireland and Rosen 1990, Kaplansky 1999). The case of third powers corresponds to numbers having exactly six divisors, the case of forth powers to numbers having eight divisors, and so on.

P	Forms	Sloane	n
2	p^3, pq	A007422	6, 8, 10, 14, 15, 21, 22, ...
3	p^5, p^2q	A030515	12, 18, 20, 28, 32, 44, ...
4	p^7, p^3q, pqr	A030626	24, 30, 40, 42, 54, 56, ...
5	p^9, p^4q	A030628	48, 80, 112, 162, 176, ...

Dixon's Factorization Method

In order to find INTEGERS x and y such that

$$x^2 \equiv y^2 \pmod{n} \quad (1)$$

(a modified form of FERMAT'S FACTORIZATION METHOD), in which case there is a 50% chance that $\mathrm{GCD}(n, x-y)$ is a FACTOR of n, choose a RANDOM INTEGER r_i, compute

$$g(r_i) \equiv r_i^2 \pmod{n}, \quad (2)$$

and try to factor $g(r_i)$. If $g(r_i)$ is not easily factorable (up to some small trial divisor d), try another r_i. In practice, the trial rs are usually taken to be $\lfloor\sqrt{n}\rfloor + k$, with $k = 1, 2, \ldots$, which allows the QUADRATIC SIEVE factorization method to be used. Continue finding and factoring $g(r_i)$s until $N \equiv \pi d$ are found, where π is the PRIME COUNTING FUNCTION. Now for each $g(r_i)$, write

$$g(r_i) = p_{1i}^{a_{1i}} p_{2i}^{a_{2i}} \cdots p_{Ni}^{a_{Ni}}, \quad (3)$$

and form the EXPONENT VECTOR

$$\mathbf{v}(r_i) = \begin{bmatrix} a_{1i} \\ a_{2i} \\ \vdots \\ a_{Ni} \end{bmatrix}. \quad (4)$$

Now, if a_{ki} are even for any k, then $g(r_i)$ is a SQUARE NUMBER and we have found a solution to (1). If not, look for a LINEAR COMBINATION $\Sigma_i c_i \mathbf{v}(r_i)$ such that the elements are all even, i.e.,

$$c_1 \begin{bmatrix} a_{11} \\ a_{21} \\ \vdots \\ a_{N1} \end{bmatrix} + c_2 \begin{bmatrix} a_{12} \\ a_{22} \\ \vdots \\ a_{N2} \end{bmatrix} + \cdots + c_N \begin{bmatrix} a_{1N} \\ a_{2N} \\ \vdots \\ a_{NN} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \pmod{2} \quad (5)$$

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1N} \\ a_{21} & a_{22} & \cdots & a_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ a_{N1} & a_{N2} & \cdots & a_{NN} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_N \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \pmod{2}. \quad (6)$$

Since this must be solved only mod 2, the problem can be simplified by replacing the a_{ij}s with

$$b_{ij}=\begin{cases}0 & \text{for } a_{ij} \text{ even}\\ 1 & \text{for } a_{ij} \text{ odd.}\end{cases} \quad (7)$$

GAUSSIAN ELIMINATION can then be used to solve

$$\mathbf{bc}=\mathbf{z} \quad (8)$$

for **c**, where **z** is a VECTOR equal to 0 (mod2) . Once **c** is known, then we have

$$\prod_k g(r_k)\equiv\prod_k r_k^2 \ (\mathrm{mod} n), \quad (9)$$

where the products are taken over all k for which $c_k=1$. Both sides are PERFECT SQUARES, so we have a 50% chance that this yields a nontrivial factor of n. If it does not, then we proceed to a different **z** and repeat the procedure. There is no guarantee that this method will yield a factor, but in practice it produces factors faster than any method using trial divisors. It is especially amenable to parallel processing, since each processor can work on a different value of r.

Dixon's Random Squares Factorization Method

DIXON'S FACTORIZATION METHOD

Dixon's Theorem

$$\begin{aligned}{}_3F_2\left[\begin{matrix}n,-x,-y\\ x+n+1,y+n+1\end{matrix}\right]&=\Gamma(x+n+1)\Gamma(y+n+1)\Gamma\\ &\times\left(\frac{1}{2}n+1\right)\Gamma\left(x+y+\frac{1}{2}n+1\right)\\ &\times\Gamma(n+1)\Gamma(x+y+n+1)\Gamma\\ &\times\left(x+\frac{1}{2}n+1\right)\Gamma\left(y+\frac{1}{2}n+1\right),\end{aligned} \quad (1)$$

where ${}_3F_2(a,b,c;d,e;z)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION and $\Gamma(z)$ is the GAMMA FUNCTION. It can be derived from the DOUGALL-RAMANUJAN IDENTITY. It can be written more symmetrically as

$${}_3F_2(a,b,c;d,e;1)=\frac{\left(\frac{1}{2}a\right)!(a-b)!(a-c)!\left(\frac{1}{2}a-b-c\right)!}{a!\left(\frac{1}{2}a-b\right)!\left(\frac{1}{2}a-c\right)!(a-b-c)!}, \quad (2)$$

where $1+a/2-b-c$ has a positive REAL PART, $d=a-b+1$, and $e=a-c+1$ (Bailey 1935, p. 13; Petkovsek 1996; Koepf 1998, p. 32). The identity can also be written as the beautiful symmetric sum

$$\sum_k(-1)^k\binom{a+b}{a+k}\binom{a+c}{c+k}\binom{b+c}{b+k}=\frac{(a+b+c)!}{a!b!c!} \quad (3)$$

(Petkovsek 1996). In this form, it closely resembles DIXON'S IDENTITY.

Jacobi Elliptic Functions

D-Number

A natural number $n > 3$ such that

$$n|(a^{n-2}-a)$$

whenever $(a,n)=1$ (a and n are relatively prime) and $a \leq n$. (Here, $n|m$ means that n divides m.) There are an infinite number of such numbers, the first few being 9, 15, 21, 33, 39, 51, ... (Sloane's A033553).

See also Divide, Knödel Numbers

References

Makowski, A. "Generalization of Morrow's D-Numbers." *Simon Stevin* **36**, 71, 1962/1963.

Dobinski's Formula

The general formula states that

$$\phi_n(x)=e^{-x}\sum_{k=0}^\infty \frac{k^n}{k!}x^k, \qquad (1)$$

where $\phi_n(x)$ is an exponential polynomial (Roman 1984, p. 66). Setting $x=1$ gives the special case of the nth Bell number,

$$B_n=\frac{1}{e}\sum_{k=0}^\infty \frac{k^n}{k!}. \qquad (2)$$

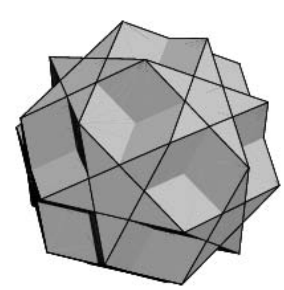
It can be derived by dividing the formula for a Stirling number of the second kind by $m!$, yielding

$$\frac{m^n}{m!}=\sum_{k=1}^m \left\{ {n \atop k} \right\} \frac{1}{(m-k)!}. \qquad (3)$$

Then

$$\sum_{k=1}^\infty \frac{m^n}{m!}\lambda^m=\left(\sum_{k=1}^n \left\{ {n \atop k} \right\}\lambda^k\right)\left(\sum_{k=0}^\infty \frac{\lambda^j}{j!}\right), \qquad (4)$$

and



$$\sum_{k=1}^n \left\{ {n \atop k} \right\}\lambda^k=e^{-\lambda}\sum_{m=1}^\infty \frac{m^n}{m!}\lambda^m. \qquad (5)$$

Now setting $\lambda=1$ gives the identity (Dobinski 1877; Rota 1964; Berge 1971, p. 44; Comtet 1974, p. 211; Roman 1984, p. 66; Lupas 1988; Wilf 1990, p. 106; Chen and Yeh 1994; Pitman 1997).

Dodecadodecahedron

The UNIFORM POLYHEDRON U_{36} whose DUAL POLYHEDRON is the MEDIAL RHOMBIC TRIACONTAHEDRON. The solid is also called the GREAT DODECADODECAHEDRON, and its DUAL POLYHEDRON is also called the SMALL STELLATED TRIACONTAHEDRON. The dodecadodecahedron has SCHLÄFLI SYMBOL $\left\{\frac{5}{2}, 5\right\}$ and WYTHOFF SYMBOL $2\left|\frac{5}{2}5\right.$. Its faces are $12\left\{\frac{5}{2}\right\}+12\{5\}$, and its CIRCUMRADIUS for unit edge length is

$$R=1.$$

It can be obtained by TRUNCATING a GREAT DODECAHEDRON or FACETING a ICOSIDODECAHEDRON with PENTAGONS and covering remaining open spaces with PENTAGRAMS (Holden 1991, p. 103).

A FACETED version is the GREAT DODECAHEMICOSAHEDRON. The CONVEX HULL of the dodecadodecahedron is an ICOSIDODECAHEDRON and the dual of the ICOSIDODECAHEDRON is the RHOMBIC TRIACONTAHEDRON, so the dual of the dodecadodecahedron is one of the RHOMBIC TRIACONTAHEDRON STELLATIONS (Wenninger 1983, p. 41).

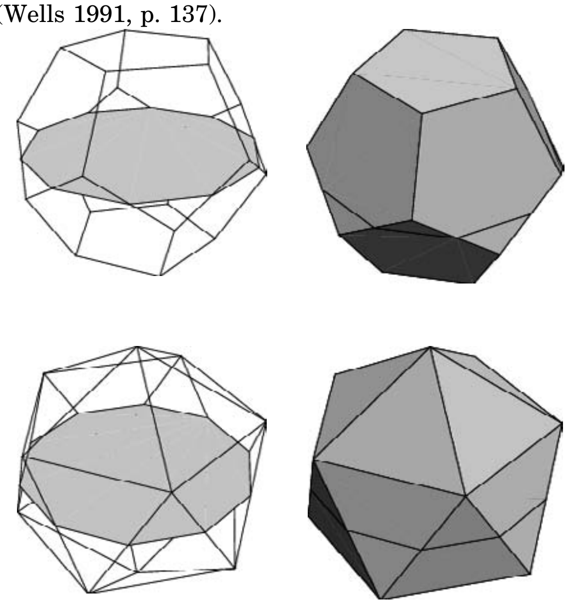
Dodecagon

A 12-sided polygon. The regular dodecagon is CONSTRUCTIBLE denoted using the SCHLÄFLI SYMBOL $\{12\}$. The INRADIUS r, CIRCUMRADIUS R, and AREA A can be computed directly from the formulas for a general REGULAR POLYGON with side length s and $n=12$ sides,

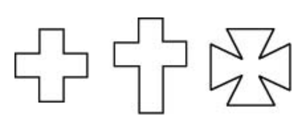
$$r=\frac{1}{2}s\cot\left(\frac{\pi}{12}\right)=\frac{1}{2}\left(2+\sqrt{3}\right)s \tag{1}$$



$$R=\frac{1}{2}s\csc\left(\frac{\pi}{12}\right)=\frac{1}{2}\left(\sqrt{2}+\sqrt{6}\right)s \tag{2}$$

$$A=\frac{1}{4}ns^2\cot\left(\frac{\pi}{12}\right)=3\left(2+\sqrt{3}\right)s^2. \tag{3}$$

KURSCHÁK'S THEOREM gives the AREA of the dodecagon inscribed in a UNIT CIRCLE with $R=1$,



$$\mathrm{A}=\frac{1}{2}nR^2\sin\left(\frac{2\pi}{n}\right)=3 \tag{4}$$

(Wells 1991, p. 137).

A PLANE PERPENDICULAR to a C_5 axis of a DODECAHEDRON or ICOSAHEDRON cuts the solid in a regular DECAGONAL CROSS SECTION (Holden 1991, pp. 24–5).

The GREEK, LATIN, and MALTESE CROSSES are all irregular dodecagons.

Dodecahedral Conjecture

In any unit SPHERE PACKING, the volume of any VORONOI CELL around any sphere is at least as large as a regular DODECAHEDRON of INRADIUS 1. If true, this would provide a bound on the densest possible sphere packing greater than any currently known. It is not, however, sufficient to establish the KEPLER CONJECTURE.

See also KEPLER CONJECTURE, SPHERE PACKING

Dodecahedral Graph

The PLATONIC GRAPH corresponding to the connectivity of the vertices of a DODECAHEDRON. Finding a HAMILTONIAN CIRCUIT on this graph is known as the ICOSIAN GAME. The dodecahedral graph has 20 nodes, 30 edges, VERTEX CONNECTIVITY 3, EDGE CONNECTIVITY 3, GRAPH DIAMETER 5, GRAPH RADIUS 5, and GIRTH 5.

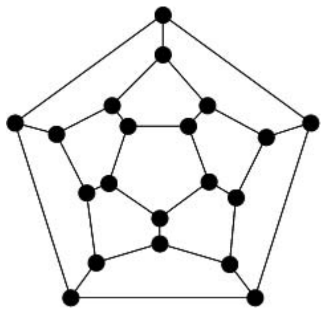
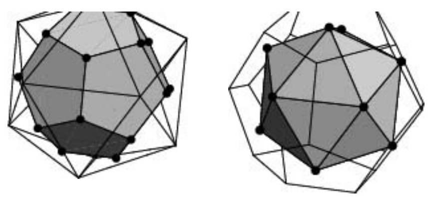
Dodecahedral Space

POINCARÉ MANIFOLD

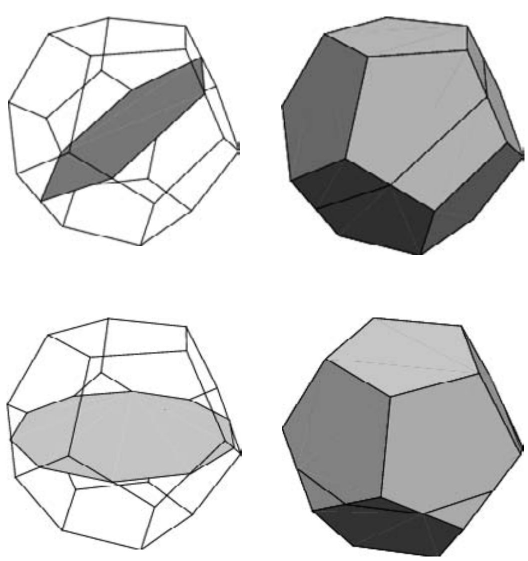
Dodecahedron



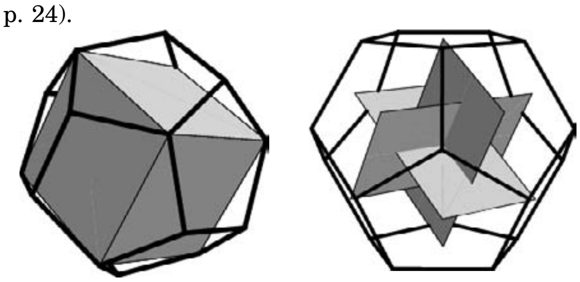


The regular dodecahedron is the PLATONIC SOLID P_4 composed of 20 VERTICES, 30 EDGES, and 12 PENTAGONAL FACES, $12\{5\}$. It is also UNIFORM POLYHEDRON U_{23} and Wenninger model W_5. It is given by the SCHLÄFLI SYMBOL $\{5,3\}$ and the WYTHOFF SYMBOL $3|25$.

Crystals of pyrite (FeS_2) resemble slightly distorted dodecahedra (Steinhaus 1983, pp. 207–08), and sphalerite (ZnS) crystals are irregular dodecahedra bounded by congruent deltoids (Steinhaus 1983, pp. 207 and 209). The HEXAGONAL SCALENOHEDRON is another irregular dodecahedron. The DELTOIDAL HEXECONTAHEDRON and TRIAKIS TETRAHEDRON are irregular dodecahedra composed of a single type of face, and the CUBOCTAHEDRON and TRUNCATED TETRAHEDRON are dodecahedral ARCHIMEDEAN SOLIDS consisting of multiple types of faces.



Dodecahedra were known to the Greeks, and 90 models of dodecahedra with knobbed vertices have been found in a number of archaeological excavations in Europe dating from the Gallo-Roman period in locations ranging from military camps to public bath houses to treasure chests (Schuur).



The dodecahedron has the ICOSAHEDRAL GROUP I_h of symmetries. The connectivity of the vertices is given by the DODECAHEDRAL GRAPH. There are three DODECAHEDRON STELLATIONS.

The DUAL POLYHEDRON of the dodecahedron is the ICOSAHEDRON, so the centers of the faces of an ICOSAHEDRON form a dodecahedron, and vice versa (Steinhaus 1983, pp. 199–01).

A PLANE PERPENDICULAR to a C_3 axis of a dodecahedron cuts the solid in a regular HEXAGONAL CROSS SECTION (Holden 1991, p. 27). A PLANE PERPENDICULAR to a C_5 axis of a dodecahedron cuts the solid in a regular DECAGONAL CROSS SECTION (Holden 1991, p. 24).

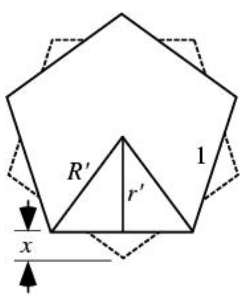
A CUBE can be constructed from the dodecahedron's vertices taken eight at a time (above left figure; Steinhaus 1983, pp. 198–99; Wells 1991). Five such cubes can be constructed, forming the CUBE 5-COMPOUND. In addition, joining the centers of the faces gives three mutually PERPENDICULAR GOLDEN RECTANGLES (right figure; Wells 1991).

The short diagonals of the faces of the RHOMBIC TRIACONTAHEDRON give the edges of a dodecahedron (Steinhaus 1983, pp. 209–10).

The following table gives polyhedra which can be constructed by CUMULATION of a dodecahedron by pyramids of given heights h.

h	$(r+h)/h$	Result
$-\sqrt{\frac{1}{10}(5-\sqrt{5})}$	$2\sqrt{5}-3$	60-faced dimpled DELTAHEDRON
$\frac{1}{19}\sqrt{\frac{1}{5}(65+22\sqrt{5})}$	$\frac{3}{19}(10-\sqrt{5})$	PENTAKIS DODECAHEDRON
$\sqrt{\frac{1}{10}(5-\sqrt{5})}$	$2\sqrt{5}-3$	60-faced star DELTAHEDRON
$\sqrt{\frac{1}{5}(5+2\sqrt{5})}$	$\sqrt{5}$	SMALL STELLATED DODECAHEDRON

When the dodecahedron with edge length $\sqrt{10-2\sqrt{5}}$ is oriented with two opposite faces parallel to the xy-PLANE, the vertices of the top and bottom faces lie at $z=\pm(\phi+1)$ and the other VERTICES lie at $z=\pm(\phi-1)$,



where ϕ is the GOLDEN RATIO. The explicit coordinates are

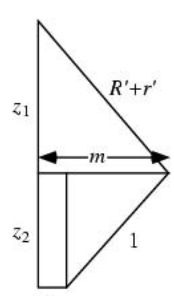
$$\pm\left(2\cos\left(\frac{2}{5}\pi i\right), 2\sin\left(\frac{2}{5}\pi i\right), \phi+1\right) \tag{1}$$

$$\pm\left(2\phi\cos\left(\frac{2}{5}\pi i\right), 2\phi\sin\left(\frac{2}{5}\pi i\right), \phi-1\right) \tag{2}$$

with $i = 0, 1, ..., 4$, where ϕ is the GOLDEN RATIO.

The VERTICES of a dodecahedron can be given in a simple form for a dodecahedron of side length $a = \sqrt{5}-1$ by $(0, \pm\phi^{-1}, \pm\phi)$, $(\pm\phi, 0, \pm\phi^{-1})$, $(\pm\phi^{-1}, \pm\phi, 0)$, and $(\pm 1, \pm 1, \pm 1)$.

For a dodecahedron of unit edge length $a = 1$, the CIRCUMRADIUS R' and INRADIUS r' of a PENTAGONAL FACE are



$$R' = \frac{1}{10}\sqrt{50+10\sqrt{5}} \tag{3}$$

$$r' = \frac{1}{10}\sqrt{25+10\sqrt{5}}. \tag{4}$$

The SAGITTA x is then given by

$$x \equiv R' - r' = \frac{1}{10}\sqrt{125-10\sqrt{5}}. \tag{5}$$

Now consider the following figure.

Using the PYTHAGOREAN THEOREM on the figure then gives

$$z_1^2 + m^2 = (R'+r)^2 \tag{6}$$

$$z_2^2 + (m-x)^2 = 1 \tag{7}$$

$$\left(\frac{z_1+z_2}{2}\right)^2 + R'^2 = \left(\frac{z_1-z_2}{2}\right)^2 + (m+r')^2. \tag{8}$$

Equation (3) can be written

$$z_1 z_2 + r^2 = (m+r')^2. \tag{9}$$

Solving (1), (2), and (9) simultaneously gives

$$m = r' = \frac{1}{10}\sqrt{25+10\sqrt{5}} \tag{10}$$

$$z_1 = 2r' = \frac{1}{5}\sqrt{25+10\sqrt{5}} \tag{11}$$

$$z_2 = R' = \frac{1}{10}\sqrt{50+10\sqrt{5}}. \tag{12}$$

The INRADIUS of the dodecahedron is then given by

$$r = \frac{1}{2}(z_1+z_2), \tag{13}$$

so

$$r^2 = \frac{1}{40}\left(25+11\sqrt{5}\right), \tag{14}$$

and solving for r gives

$$r = \frac{1}{20}\sqrt{250+110\sqrt{5}} = 1.11351\ldots \tag{15}$$

Now,

$$R^2 = R'^2 + r^2 = \frac{3}{8}\left(3+\sqrt{5}\right), \tag{16}$$

so the CIRCUMRADIUS is

$$R = \frac{1}{4}\left(\sqrt{15}+\sqrt{3}\right) = 1.40125\ldots \tag{17}$$

The INTERRADIUS is given by

$$\rho^2 = r'^2 + r^2 = \frac{1}{8}\left(7+3\sqrt{5}\right), \tag{18}$$

so

$$\rho = \frac{1}{4}\left(3+\sqrt{5}\right) = 1.30901\ldots \tag{19}$$

The DIHEDRAL ANGLE is

$$\alpha = \cos^{-1}\left(-\frac{1}{5}\sqrt{5}\right) \approx 116.57°. \tag{20}$$

The AREA of a single FACE is the AREA of a PENTAGON,

$$A = \frac{1}{4}\sqrt{25+10\sqrt{5}}. \tag{21}$$

The VOLUME of the dodecahedron can be computed by summing the volume of the 12 constituent PENTAGONAL PYRAMIDS,

$$V = 12\left(\frac{1}{3}Ar\right) = \frac{1}{4}\left(15 + 7\sqrt{5}\right). \qquad (22)$$

Apollonius showed that the VOLUME V and SURFACE AREA A of the dodecahedron and its DUAL the ICOSAHEDRON are related by

$$\frac{V_{\text{icosahedron}}}{V_{\text{dodecahedron}}} = \frac{A_{\text{icosahedron}}}{A_{\text{dodecahedron}}} \qquad (23)$$

Dodecahedron 3-Compound

See also DODECAHEDRON, DODECAHEDRON 2-COMPOUND, DODECAHEDRON 5-COMPOUND

Dodecahedron 5-Compound

There are at least two attractive 5-dodecahedra compounds. The one illustrated in the left figure above has the symmetry of the ICOSAHEDRON and can be constructed by taking a DODECAHEDRON with top and bottom vertices aligned along the z-AXIS and one vertex oriented in the direction of the x-axis, rotating about the y-AXIS by an angle

$$\alpha = \cos^{-1}\left(\sqrt{\frac{2}{15}\left(5+\sqrt{5}\right)}\right),$$

and then rotating this solid by angles $2\pi i/5$ for $i = 0$, 1, ..., 4.

The compound shown at right can be obtained by combining five dodecahedra, each rotated by 1/10 of a turn about the line joining the centroids of opposite faces.

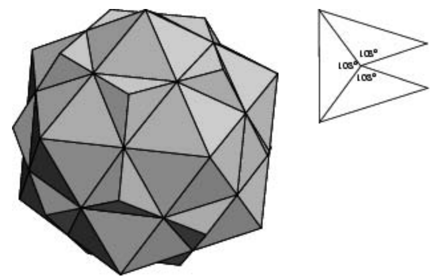
References

Wenninger, M. J. *Dual Models.* Cambridge, England: Cambridge University Press, pp. 145–47, 1983.

Dodecahedron Stellations



The dodecahedron has three STELLATIONS: the SMALL STELLATED DODECAHEDRON, GREAT DODECAHEDRON, and GREAT STELLATED DODECAHEDRON (Wenninger 1989, pp. 35 and 38–0). Bulatov has produced 270 stellations of a deformed dodecahedron.

See also DODECAHEDRON, ICOSAHEDRON STELLATIONS, STELLATED POLYHEDRON, STELLATION

References

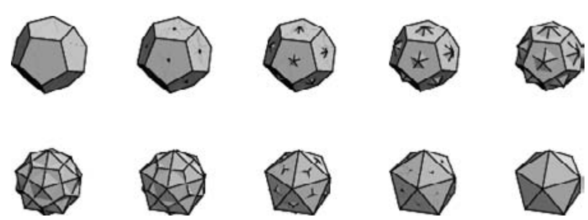
Wenninger, M. J. *Polyhedron Models.* New York: Cambridge University Press, pp. 35 and 38–0, 1989.

Dodecahedron-Icosahedron Compound

A POLYHEDRON COMPOUND consisting of a DODECAHEDRON and its dual the ICOSAHEDRON. It is most easily constructed by adding 20 triangular PYRAMIDS, constructed as above, to an ICOSAHEDRON. In the compound, the DODECAHEDRON and ICOSAHEDRON are rotated $\pi/5$ radians with respect to each other, and the ratio of the ICOSAHEDRON to DODECAHEDRON edges lengths are the GOLDEN RATIO ϕ.

If the DODECAHEDRON is chosen to have unit edge length, the resulting compound has side lengths



$$s_1 = \frac{1}{2} \tag{1}$$

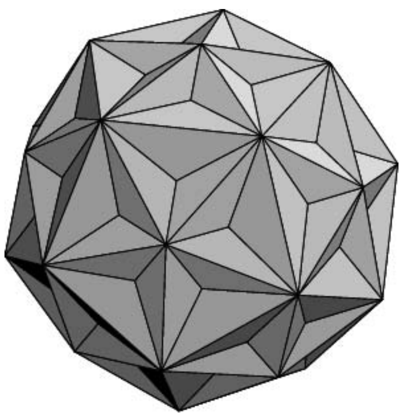
$$s_2 = \frac{1}{4}\left(1+\sqrt{5}\right). \tag{2}$$

Normalizing so that $s_1 = 1$ gives SURFACE AREA and VOLUME

$$S = 15\sqrt{13+5\sqrt{5}+\sqrt{6(25+11\sqrt{5}}} \tag{3}$$

$$V = \frac{5}{2}\left(15+7\sqrt{5}\right). \tag{4}$$

The above figure shows compounds composed of a DODECAHEDRON of unit edge length and ICOSAHEDRA having edge lengths varying from $\sqrt{5}/2$ (inscribed in the dodecahedron) to 2 (circumscribed about the dodecahedron).



The intersecting edges of the compound form the DIAGONALS of the 30 RHOMBUSES constituting the TRIACONTAHEDRON, which is the DUAL POLYHEDRON

of the ICOSIDODECAHEDRON (Ball and Coxeter 1987). The dodecahedron-icosahedron compound is also the first STELLATION of the ICOSIDODECAHEDRON.

Dodecahedron-Small Triambic Icosahedron Compound

A stellated form of a truncated icosahedron, but a *different* truncation than in the TRUNCATED ICOSAHEDRON ARCHIMEDEAN SOLID. It contains curious but attractive patterns of raised regular pentagrams and irregular hexagrams. For the solid constructed from a DODECAHEDRON with unit edge lengths, the SURFACE AREA is given by the root of a 10 order polynomial with large integer coefficients, and the VOLUME is given by

$$V=\frac{1}{20}\left(35+15\sqrt{15}-4\sqrt{650-290\sqrt{5}}\right).$$

Dominance

The dominance RELATION on a SET of points in EUCLIDEAN n-space is the INTERSECTION of the n coordinate-wise orderings. A point p dominates a point q provided that every coordinate of p is at least as large as the corresponding coordinate of q.

A PARTITION p_a dominates a PARTITION p_b if, for all k, the sum of the k largest parts of p_a is $\geq$ the sum of the k largest parts of p_b. For example, for $n=7$, $\{7\}$ dominates all other PARTITIONS, while $\{1,1,1,1,1,1,1\}$ is dominated by all others. In contrast, $\{3,1,1,1,1\}$ and $\{2,2,2,1\}$ do not dominate each other (Skiena 1990, p. 52).

The dominance orders in $\mathbb{R}^n$ are precisely the POSETS of DIMENSION at most n.

Dominant Set

DOMINANCE, DOMINATING SET

Dominating Set

This entry contributed by NICOLAS BRAY

For a GRAPH G and a subset S of the VERTEX SET $V(G)$, denote by $N_G[S]$ the set of vertices in G which are in S or adjacent to a vertex in S. If $N_G[S] = V(G)$, then S is said to be a dominating set (of vertices in G).

See also DOMINANCE, DOMINATION NUMBER

Domination Number

This entry contributed by NICOLAS BRAY

The domination number of a graph G, denoted $\gamma(G)$, is the minimum size of a DOMINATING SET of vertices in G.

See also DOMINANCE, DOMINATING SET, VIZING CONJECTURE

Domineering

A two-player game, also called crosscram, in which player H has horizontal DOMINOES and player V has vertical DOMINOES. The two players alternately place a domino on a BOARD until the other cannot move, in which case the player having made the last move wins (Gardner 1974, Lachmann *et al.* 2000). Depending on the dimension of the board, the winner will be H, V, 1 (the player making the first move), or 2 (the player making the second move). For example, the (2×2) board is a win for the first player.

Berlekamp (1988) solved the general problem for $2 \times n$ board for odd n. Solutions for the $2 \times n$ board are summarized in the following table, with $2 \times n$ a win for H for $n \geq 28$..

n	win	n	win	n	win
0	2	10	1	20	H
1	V	11	1	21	H
2	1	12	H	22	H
3	1	13	2	23	1
4	H	14	1	24	H
5	V	15	1	25	H
6	1	16	H	26	H
7	1	17	H	27	1
8	H	18	1	28	H
9	V	19	1	29	H

Lachmann *et al.* (2000) have solved the game $k \times n$ for widths of $n = 2$, 3, 4, 5, 7, 9, and 11, obtaining the results summarized in the following table for $k = 0$, 1, ...

n	winner
3	2, V, 1, 1, H, H, ...
4	H for even $k \geq 8$ and all $k \geq 22$
5	2, V, H, V, H, 2, H, H, ...
7	H for $n \geq 8$
9	H for $n \geq 22$
11	H for $n \geq 56$

Domino

The unique 2-POLYOMINO consisting of two equal squares connected along a complete EDGE.

The FIBONACCI NUMBER F_{n+1} gives the number of ways for 2×1 dominoes to cover a $2 \times n$ CHECKERBOARD, as illustrated in the following diagrams (Dickau).

TORUS

Doob's Theorem

A theorem proved by Doob (1942) which states that any random process which is both GAUSSIAN and MARKOV has the following forms for its correlation function $C_y(\tau)$, spectral density $G_y(f)$, and probability densities $p_1(y)$ and $p_2(y_1|y_2, \tau)$ ::

$$C_y \tau = \sigma_y^2 e^{-\tau/\tau_r}$$

$$G_y(f) = \frac{4\tau_\tau^{-1}\sigma_y^2}{(2\pi f)^2 + \tau_\tau^{-2}}$$

$$p_1(y) = \frac{1}{\sqrt{2\pi\sigma_y^2}} e^{-(y-\bar{y})^2/2\sigma_y^2}$$

$$p_2(y_1/y_2, \tau) = \frac{1}{\sqrt{2\pi(1 - e^{-\tau/\tau_\tau})\sigma_y^2}} \exp \times \left\{ -\frac{\left[(y_2 - \bar{y}) - e^{-\tau/\tau_\tau}(y_1 - \bar{y})\right]^2}{2(1 - e^{-2\tau/\tau_\tau})\sigma_y^2} \right\},$$

where $\bar{y}$ is the MEAN, σ_y the STANDARD DEVIATION, and τ_r the relaxation time.

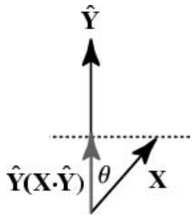
Dorman-Luke Construction



DUAL POLYHEDRON

Dot

The "dot" $\cdot$ has several meanings in mathematics, including MULTIPLICATION ($a.b$ is pronounced "a times b"), computation of a DOT PRODUCT (**ab** is pronounced "**a** dot **b**").

See also DERIVATIVE, DOT PRODUCT, OVERDOT, TIMES

Dot Product

The dot product can be defined for two VECTORS **X** and **Y** by

$$\mathbf{X}\cdot\mathbf{Y} = |\mathbf{X}||\mathbf{Y}| \cos\theta, \tag{1}$$

where θ is the ANGLE between the VECTORS. It follows immediately that $\mathbf{X}\cdot\mathbf{Y} = 0$ if **X** is PERPENDICULAR to **Y**. The dot product therefore has the geometric interpretation as the length of the PROJECTION of **X** onto the UNIT VECTOR $\bar{\mathbf{Y}}$ when the two vectors are placed so that their tails coincide.

By writing

$$A_x = A\cos\theta_A \quad B_x = B\cos\theta_B \tag{2}$$

$$A_y = A\sin\theta_A \quad B_y = B\sin\theta_B, \tag{3}$$

it follows that (1) yields

$$\begin{aligned}\mathbf{A}\cdot\mathbf{B} &= AB\cos(\theta_A - \theta_B)\\ &= AB(\cos\theta_A\cos\theta_B + \sin\theta_A\sin\theta_B)\\ &= A\cos\ \theta_A B\cos\theta_B + A\sin\theta_A B\sin\theta_B\\ &= A_xB_x + A_yB_y.\end{aligned} \tag{4}$$

So, in general,

$$\mathbf{X}\cdot\mathbf{Y} = \sum_{i=1}^{n} x_iy_i = x_1y_1 + \cdots + x_ny_n. \tag{5}$$

This can be written very succinctly using EINSTEIN SUMMATION notation as

$$\mathbf{X}\cdot\mathbf{Y} = x_iy_i. \tag{6}$$

The dot product is implemented in *Mathematica* as `Dot[a, b]`, or simply by using a period, `a . b`.

The dot product is COMMUTATIVE

$$\mathbf{X}\cdot\mathbf{Y} = \mathbf{Y}\cdot\mathbf{X}, \tag{7}$$

ASSOCIATIVE

$$(r\mathbf{X})\cdot\mathbf{Y} = r(\mathbf{X}\cdot\mathbf{Y}), \tag{8}$$

and DISTRIBUTIVE

$$\mathbf{X}\cdot(\mathbf{Y}+\mathbf{Z}) = \mathbf{X}\cdot\mathbf{Y} + \mathbf{X}\cdot\mathbf{Z}. \tag{9}$$

The DERIVATIVE of a dot product of VECTORS is

$$\frac{d}{dt}[\mathbf{r}_1(t)\cdot\mathbf{r}_2(t)] = \mathbf{r}_1(t)\cdot\frac{d\mathbf{r}_2}{dt} + \frac{d\mathbf{r}_1}{dt}\cdot\mathbf{r}_2(t). \tag{10}$$

The dot product is invariant under rotations

$$\begin{aligned}\mathbf{A}'.\mathbf{B}' &= A_i'.B_i' = a_{ij}A_ja_{ik}B_k = (a_{ij}a_{ik})A_jB_k\\ &= \delta_{jk}A_jB_k = A_jB_j = \mathbf{A}\cdot\mathbf{B},\end{aligned} \tag{11}$$

where EINSTEIN SUMMATION has been used.

The dot product is also called the scalar product and INNER PRODUCT. In the latter context, it is usually written $\langle a, b\rangle$. The dot product is also defined for TENSORS A and B by

$$A\cdot B \equiv A^\alpha B_\alpha. \tag{12}$$

Double Bubble

A double bubble is pair of BUBBLES which intersect and are separated by a membrane bounded by the intersection. The usual double bubble is illustrated in the left figure above. A more exotic configuration in which one bubble is torus-shaped and the other is shaped like a dumbbell is illustrated at right (illustrations courtesy of J. M. Sullivan).

In the plane, the analog of the double bubble consists of three circular arcs meeting in two points. It has been proved that the configuration of arcs meeting at equal 120° ANGLES) has the minimum PERIMETER for enclosing two equal areas (Alfaro *et al.* 1993, Morgan 1995).

It had been conjectured that two *equal* partial SPHERES sharing a boundary of a flat disk separate two volumes of air using a total SURFACE AREA that is less than any other boundary. This equal-volume case was proved by Hass *et al.* (1995), who reduced the problem to a set of 200,260 integrals which they carried out on an ordinary PC. Frank Morgan, Michael Hutchings, Manuel Ritoré, and Antonio Ros finally proved the conjecture for arbitrary double bubbles in early 2000. In this case of two unequal partial spheres, Morgan *et al.* showed that the separating boundary which minimizes total surface area is a portion of a SPHERE which meets the outer spherical surfaces at DIHEDRAL ANGLES of 120°. Furthermore, the CURVATURE of the partition is simply the difference of the CURVATURES of the two bubbles.

Amazingly, a group of undergraduates has extended the theorem to 4-dimensional double bubbles, as well as certain cases in 5-space and higher dimensions. The corresponding triple bubble conjecture remains open (Cipra 2000).

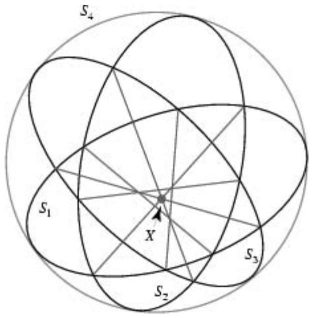
Double Bubble Conjecture

DOUBLE BUBBLE

Double Cone



Two CONES placed apex to apex. The double cone is given by algebraic equation

$$\frac{x^2}{c^2} = \frac{x^2 + y^2}{a^2}.$$

See also BICONE, CONE, NAPPE

Double Contact Theorem

If S_1, S_2, and S_3 are three conics having the property that there is a point X, not on any of the conics, lying on a common chord of each pair of the three conics (with the chords in question being distinct), then there exists a conic S_4 that has a double contact with each of S_1, S_2, and S_3 (Evelyn *et al.* 1974, p. 18). The converse of the theorem states that if three conics S_1, S_2, and S_3 all have double contact with another S_4 then each two of S_1, S_2, and S_3 have a "distinguished" pair of opposite common chords, the three such pairs of common chords being the pairs of opposite sides of a COMPLETE QUADRANGLE (Evelyn *et al.* 1974, p. 19).

The dual theorems are stated as follows. If three conics are such that, taken by pairs, they have couples of common tangents intersecting at three distinct points on a line (that is not itself a tangent to any of the conics), then (a) the conics have this property in four different ways, and (b) the conics all have double contact with a fourth. And, conversely, if three conics each have double contact with a fourth, then certain of their common tangents intersect by pairs at the vertices of a COMPLETE QUADRILATERAL (Evelyn *et al.* 1974, p. 22).

A degenerate case of the theorem gives the result that the six SIMILITUDE CENTERS of three circles taken by pairs are the vertices of a COMPLETE QUADRILATERAL (Evelyn *et al.* 1974, pp. 21–2).

Double Contraction Relation

A TENSOR t is said to satisfy the double contraction relation when

$$\bar{t}^m_{ij} t^n_{ij} = \delta_{mn}.$$

This equation is satisfied by

$$\hat{t}^0 = \frac{2\hat{\mathbf{z}}\hat{\mathbf{z}} - \hat{\mathbf{x}}\hat{\mathbf{x}} - \hat{\mathbf{y}}\hat{\mathbf{y}}}{\sqrt{6}}$$

$$\hat{t}^{\pm 1} = \mp\frac{1}{2}(\hat{\mathbf{x}}\hat{\mathbf{z}} + \hat{\mathbf{z}}\hat{\mathbf{x}}) - \frac{1}{2}i(\hat{\mathbf{y}}\hat{\mathbf{z}}\text{-}\hat{\mathbf{z}}\hat{\mathbf{y}})$$

$$\hat{t}^{\pm 2} = \mp\frac{1}{2}(\hat{\mathbf{x}}\hat{\mathbf{x}} + \hat{\mathbf{y}}\hat{\mathbf{y}}) - \frac{1}{2}i(\hat{\mathbf{x}}\hat{\mathbf{y}}\text{-}\hat{\mathbf{y}}\hat{\mathbf{x}}),$$

where the hat denotes zero trace, symmetric unit TENSORS. These TENSORS are used to define the SPHERICAL HARMONIC TENSOR.

Double Factorial

The double factorial is a generalization of the usual FACTORIAL $n!$ defined by

$$n!! \equiv \begin{cases} n\cdot(n-2)\ldots 5.3.1 & n \text{ odd} \\ n\cdot(n-2)\ldots 6.4.2 & n \text{ even} \\ 1 & n=-1,0 \end{cases}. \tag{1}$$

Note that $-1!!=0!!=1$, by definition (Arfken 1985, p. 547). For $n=0$, 1, 2, ..., the first few values are 1, 1, 2, 3, 8, 15, 48, 105, 384, ... (Sloane's A006882). The double factorial is implemented in *Mathematica* as $n!!$ or `Factorial2[n]`. The double factorial is a special case of the MULTIFACTORIAL.

The double factorial can be expressed in terms of the GAMMA FUNCTION by

$$\Gamma\left(n+\frac{1}{2}\right)=\frac{(2n-1)!!}{2^n}\sqrt{\pi} \tag{2}$$

(Arfken 1985, p. 548).

There are many identities relating double factorials to FACTORIALS. Since

$$\begin{aligned}&(2n+1)!!2^n n!\\ &=[(2n+1)(2n-1)\ldots 1][2n][2(n-1)][2(n-2)]\ldots 2(1)\\ &=[(2n+1)(2n-1)\cdots 1][2n(2n-2)(2n-4)\cdots 2]\\ &=(2n+1)(2n)(2n-1)(2n-2)(2n-3)(2n-4)\cdots 2(1)\\ &=(2n+1)!,\end{aligned} \tag{3}$$

it follows that $(2n+1)!!=\frac{(2n+1)!}{2^n n!}$. For $n=0$, 1, ..., the first few values are 1, 3, 15, 105, 945, 10395, ... (Sloane's A001147).

Also, since

$$\begin{aligned}(2n+1)!!&=(2n)(2n-2)(2n-4)\cdots 2\\ &=[(2n)][2(n-1)][2(n-2)]\cdots 2=2^n n!,\end{aligned} \tag{4}$$

it follows that $(2n)!!=2^n n!$. For $n=0$, 1, ..., the first few values are 1, 2, 8, 48, 384, 3840, 46080, ... (Sloane's A000165).

Finally, since

$$\begin{aligned}&(2n-1)!!2^n n!\\ &=[(2n-1)(2n-3)\cdots 1][(2n)][2(n-1)]\\ &\quad\times[2(n-2)]\cdots 2(1)\\ &=(2n-1)(2n-3)\cdots 1[2n(2n-2)(2n-4)\cdots 2]\\ &=2n(2n-1)(2n-2)(2n-3)(2n-4)\cdots 2(1)\\ &=(2n)!,\end{aligned} \tag{5}$$

it follows that

$$(2n-1)!!=\frac{(2n)!}{2^n n!}. \tag{6}$$

The double factorial can also be extended to negative odd integers using the definition

$$(-2n-1)!!=\frac{(-1)^n}{(2n-1)!!}=\frac{(-1)^n 2^n n!}{(2n)!} \tag{7}$$

for $n=0$, 1, ... (Arfken 1985, p. 547). Similarly, the double factorial can be extended to complex arguments as

$$z!!=2^{[1+2x-\cos(\pi x)]/4}\pi^{[\cos(\pi x)-1]/4}\Gamma\left(1+\frac{1}{2}x\right). \tag{8}$$

For n ODD,

$$\begin{aligned}\frac{n!}{n!!}&=\frac{n(n-1)(n-2)\cdots(1)}{n(n-2)(n-4)\cdots(1)}\\ &=(n-1)(n-3)\cdots(1)=(n-1)!!.\end{aligned} \tag{9}$$

For n EVEN,

$$\begin{aligned}\frac{n!}{n!!}&=\frac{n(n-1)(n-2)\cdots(2)}{n(n-2)(n-4)\cdots(2)}\\ &(n-1)(n-3)\cdots(2)=(n-1)!!.\end{aligned} \tag{10}$$

Therefore, for any n,

$$\frac{n!}{n!!}=(n-1)!! \tag{11}$$

$$n!=n!!(n-1)!!. \tag{12}$$

A closed-form sum due to Ramanujan is given by

$$\sum_{n=0}^{\infty}(-1)^n\left[\frac{(2n-1)!!}{(2n)!!}\right]^3=\left[\frac{\Gamma\left(\frac{9}{8}\right)}{\Gamma\left(\frac{5}{4}\right)\Gamma\left(\frac{7}{8}\right)}\right]^2 \tag{13}$$

(Hardy 1999, p. 106). Whipple (1926) gives a generalization of this sum (Hardy 1999, pp. 111–12).

Double Series

A SERIES having terms depending on two indices,

$$\sum_{i,j} a_{ij}.$$

Identities involving double sums include the following:

$$\sum_{p=0}^{\infty}\sum_{q=0}^{p} a_{q,p-q} = \sum_{m=0}^{\infty}\sum_{n=0}^{\infty} a_{n,m} = \sum_{r=0}^{\infty}\sum_{s=0}^{\lfloor r/2 \rfloor} a_{s,r-2s}, \qquad (1)$$

where

$$\lfloor r/2 \rfloor = \begin{cases} \frac{1}{2}r & r \text{ even} \\ \frac{1}{2}(r-1) & r \text{ odd} \end{cases} \qquad (2)$$

is the FLOOR FUNCTION, and

$$\sum_{i=1}^{\infty}\sum_{j=1}^{p} x_i x_j = n^2 \langle x^2 \rangle. \qquad (3)$$

Consider the series

$$S(a,b,c;s) = \sum_{(m,n)\neq(0,0)} \left(am^2 + bmn + cn^2\right)^{-s} \qquad (4)$$

over binary QUADRATIC FORMS. If S can be decomposed into a linear sum of products of DIRICHLET L-SERIES, it is said to be solvable. The related sums

$$S_1(a,b,c;s) = \sum_{(m,n)\neq(0,0)} (-1)^m \left(am^2 + bmn + cn^2\right)^{-s} \qquad (5)$$

$$S_2(a,b,c;s) = \sum_{(m,n)\neq(0,0)} (-1)^n \left(am^2 + bmn + cn^2\right)^{-s} \qquad (6)$$

$$S_{1,2}(a,b,c;s) = \sum_{(m,n)\neq(0,0)} (-1)^{m+n} \left(am^2 + bmn + cn^2\right)^{-s} \qquad (7)$$

can also be defined, which gives rise to such impressive FORMULAS as

$$S_1(1,0,58;1) = -\frac{\pi \ln\left(27 + 5\sqrt{29}\right)}{\sqrt{58}} \qquad (8)$$

(Glasser and Zucker 1976b). A complete table of the principal solutions of all solvable $S(a,b,c;s)$ is given in Glasser and Zucker (1980, pp. 126–31).

The LATTICE SUM $b_2(2s)$ can be separated into two pieces,

$$b_2(2s) = \sum_{i,\,j=-\infty}^{\infty} \frac{(-1)^{i+j}}{(i^2+j^2)^s}$$

$$= \sum_{i=1}^{\infty}\sum_{j=1}^{\infty} \frac{(-1)^{i+j}}{(i^2+j^2)^2} + \sum_{i=1}^{\infty}\sum_{j=-1}^{-\infty} \frac{(-1)^{i+j}}{(i^2+j^2)^2}$$

$$+ \sum_{i=-1}^{-\infty}\sum_{j=1}^{\infty} \frac{(-1)^{i+j}}{(i^2+j^2)^2} + \sum_{i=-1}^{-\infty}\sum_{j=-1}^{-\infty} \frac{(-1)^{i+j}}{(i^2+j^2)^2}$$

$$+ \sum_{j=-\infty}^{-1} \frac{(-1)^j}{j^{2s}} + \sum_{j=1}^{\infty} \frac{(-1)^j}{j^{2s}} + \sum_{j=-\infty}^{-1} \frac{(-1)^i}{i^{2s}} + \sum_{i=1}^{\infty} \frac{(-1)^i}{i^{2s}}$$

$$= 4\left[\sum_{i,\,j=1}^{\infty} \frac{(-1)^{i+j}}{(i^2+j^2)^s} + \sum_{i=1}^{\infty} \frac{(-1)^i}{i^{2s}}\right]$$

$$= 4\left[\sum_{i,\,j=1}^{\infty} \frac{(-1)^{i+j}}{(i^2+j^2)^s} + \eta(2s)\right] \qquad (9)$$

where $\eta(n)$ is the DIRICHLET ETA FUNCTION. Using the analytic form of the LATTICE SUM

$$b_2(s) = -4\beta(s)\eta(s) = 4\left[S_{1,2}(1,0,1;s) - \eta(2s)\right], \qquad (10)$$

where $\beta(s)$ is the DIRICHLET BETA FUNCTION gives the sum

$$S_{1,2}(1,0,1;s) = \sum_{i,\,j=1}^{\infty} \frac{(-1)^{i+j}}{(i^2+j^2)^2} = \eta(2s) - \eta(s)\beta(s). \qquad (11)$$

Borwein and Borwein (1986, p. 291) show that for $\Re[s] > 1$,

$$\sum_{i,\,j=-\infty}^{\infty} \frac{1}{(i^2+j^2)^s} = 4\beta(s)\zeta(s) \qquad (12)$$

$$\sum_{i,\,j=-\infty}^{\infty} \frac{(-1)^j}{(i^2+j^2)^s} = 2^{-s} b_2(2s), \qquad (13)$$

where $\zeta(s)$ is the RIEMANN ZETA FUNCTION, and for appropriate s,

$$\sum_{i,\,j=-1}^{\infty} \frac{(-1)^{i+j}}{(i+j)^s} = \eta(s) - \eta(s-1) \qquad (14)$$

$$\sum_{i,\,j=1}^{\infty} \frac{(-1)^{i+j}}{(i+j)^s} = 2^{-s}\zeta(s) \qquad (15)$$

$$\sum_{i,\,j=1}^{\infty} \frac{1}{(i+j)^s} = \zeta(s-1) - \zeta(s) \qquad (16)$$

$$\sum_{i,\,j=-\infty}^{\infty} \frac{(-1)^{i+j+1}}{(|i|+|j|)^s} = 4\eta(s-1) \qquad (17)$$

$$\sum_{i,\,j=-\infty}^{\infty} \frac{1}{(i+j)^s} = 4\zeta(s-1) \qquad (18)$$

$$\sum_{i,\,j=-\infty}^{\infty}\frac{(-1)^{i+j}}{(2i+j+1)^s}=\frac{1}{2}(1-2^{-s})\eta(s)+\frac{1}{2}\beta(s) \qquad (19)$$

(Borwein and Borwein 1986, p. 305).

Another double series reduction is given by

$$\sum_{m,n=-\infty}^{\infty}\frac{F(|2m+2n+1|)}{\cosh[(2n+1)u]\cosh(2nu)}$$
$$=2\sum_{n=0}^{\infty}\frac{(2n+1)F(2n+1)}{\sinh[(2n+1)u]}, \qquad (20)$$

where F denotes any function (Glasser 1974).

Double Sixes

Two sextuples of SKEW LINES on the general CUBIC SURFACE such that each line of one is SKEW to one LINE in the other set. In all, there are 30 points, with two lines through each point, and 12 lines with five points on each line. Two lines can be placed in the plane of each of the faces of a cube. The double sixes were discovered by Schläfli.

Double-Angle Formulas

Formulas expressing trigonometric functions of an angle $2x$ in terms of functions of an angle x,

$$\sin(2x)=2\sin x\cos x \qquad (1)$$

$$\cos(2x)=\cos^2 x-\sin^2 x \qquad (2)$$

$$=2\cos^2 x-1 \qquad (3)$$

$$=1-2\sin^2 x \qquad (4)$$

$$\tan(2x)=\frac{2\tan x}{1-\tan^2 x}. \qquad (5)$$

The corresponding hyperbolic function double-angle formulas are

$$\sinh(2x)=2\sinh x\cosh x \qquad (6)$$

$$\cosh(2x)-2\cosh^2 x-1 \qquad (7)$$

$$\tanh(2x)=\frac{2\tanh x}{1+\tanh^2 x}. \qquad (8)$$

See also HALF-ANGLE FORMULAS, HYPERBOLIC FUNCTIONS, MULTIPLE-ANGLE FORMULAS, PROSTHAPHAERESIS FORMULAS, TRIGONOMETRIC ADDITION FORMULAS, TRIGONOMETRIC FUNCTIONS, TRIGONOMETRY

Double-Free Set

A SET of POSITIVE INTEGERS is double-free if, for any integer x, the SET $\{x, 2x\} \notin S$ (or equivalently, $x \in S$ IMPLIES $2x \notin S$). For example, of the subsets of $\{1, 2, 3\}$, the sets Ø, $\{1\}$, $\{2\}$, $\{2, 3\}$, $\{1, 3\}$, and $\{3\}$ are double-free, while $\{1, 2\}$ and $\{1, 2, 3\}$ are not.

The number $a(n)$ of double-free subsets of $\{1, 2, \ldots, n\}$ can be computed using $a(1) = 2$ and the RECURRENCE RELATION

$$a(n) = a(n-1)\frac{F_{b(n)+3}}{F_{b(n)+2}}, \qquad (1)$$

where F_n is a FIBONACCI NUMBER, 1, 1, 2, 3, 5, 8, ... (Sloane's A000045), and $b(n)$ is the BINARY CARRY SEQUENCE giving the number of trailing 0s is the BINARY representation of n, 0, 1, 0, 2, 0, 1, 3, 0, 1, ... (Sloane's A007814) (C. Bower). For $n = 1$, 2, ..., $a(n)$ are given by are 2, 3, 6, 10, 20, 30, 60, 96, 192, ... (Sloane's A050291).

Define

$$r(n) = \max\{|s| : S \subset \{1, 2, \ldots, n\} \text{ is double-free}\}, \qquad (2)$$

where $|S|$ is the CARDINAL NUMBER of (number of members in) S. Then for $n = 1$, 2, ..., $r(n)$ is given by 1, 1, 2, 3, 4, 4, 5, 5, 6, 6, 7, 8, 9, 9, 10, ... (Sloane's A050292). An explicit formula for $r(n)$ is given by

$$r(n) = \sum_{i=1}^{n} p(i), \qquad (3)$$

where

$$p(i) = \begin{cases} 1 & \text{if } b(i) \text{ is even} \\ 0 & \text{if } b(i) \text{ is odd} \end{cases} \qquad (4)$$

where $b(n)$ is defined above and the first few values of $p(i)$ are 1, 0, 1, 1, 1, 0, 1, 0, 1, 0, 1, 1, 1, ... (Sloane's A035263; C. Bower). A simple RECURRENCE RELATION for $r(n)$ is given by

$$f(n) = \left\lceil \frac{1}{2}n \right\rceil + f\left(\left\lfloor \frac{1}{4}n \right\rfloor\right) \qquad (5)$$

with $f(0) = 0$ (Wang 1989), where $\lfloor x \rfloor$ is the FLOOR FUNCTION and $\lceil x \rceil$ is the CEILING FUNCTION. An asymptotic formula for $r(n)$ is given by

$$r(n) \sim \frac{2}{3}n + \mathcal{O}(\log_4 n) \qquad (6)$$

(Wang 1989).

Doublestruck

A letter of the alphabet drawn with doubled vertical strokes is called doublestruck, or sometimes blackboard bold (because doublestruck characters provide a means of indicating bold font weight when writing on a blackboard). For example, $\mathbb{A}$, $\mathbb{B}$, $\mathbb{C}$, $\mathbb{D}$, $\mathbb{E}$, ... Important SETS in mathematics are commonly denoted using doublestruck characters, e.g., $\mathbb{C}$ for the set of complex numbers and $\mathbb{R}$ for the real numbers.

Doublestruck characters can be encoded using the `AMSFonts` extended fonts for LATEX using the syntax `\mathbb{`*C*`}`, and typed in *Mathematica* using the syntax `\[DoubleStruckC]` or `\[DoundStruckCapitalC]`, where C denotes any letter.

Doublet Function

$$y = \delta'(x - a),$$

where $\delta(x)$ is the DELTA FUNCTION.

Doubly Stochastic Matrix

A doubly stochastic matrix is a matrix $\mathbf{A}=(a_{ij})$ such that $a_{ij} \geq 0$ and

$$\sum_i a_{ij} = \sum_j a_{ij} = 1$$

is some field for all i and j. In other words, both the matrix itself and its transpose are STOCHASTIC.

The following tables give the number of distinct doubly stochastic matrices (and distinct nonsingular doubly stochastic matrices) over $\mathbb{Z}_m$ for small m.

m	doubly stochastic $n \times n$ matrices over $\mathbb{Z}_m$
2	1, 2, 16, 512, ...
3	1, 3, 81, ...
4	1, 4, 256, ...

m	doubly stochastic nonsingular $n \times n$ matrices over $\mathbb{Z}_m$
2	1, 2, 6, 192, ...
3	1, 2, 54, ...
4	1, 4, 192, ...

Horn (1954) proved that if $\mathbf{y} = \mathbf{Ax}$, where $\mathbf{x}$ and $\mathbf{y}$ are complex n-vectors, $\mathbf{A}$ is doubly stochastic, and c_1, c_2, ..., C_n are any complex numbers, then $\Sigma_{i=1}^n c_i y_i$ lies in the CONVEX HULL of all the points $\Sigma_{i=1}^n c_i x_{ai}$, $a \in R^n$, where R^n is the set of all permutations of $\{1, ..., n\}$. Sherman (1955) also proved the converse.

Birkhoff (1946) proved that any doubly stochastic $n \times n$ matrix is in the CONVEX HULL of m PERMUTATION MATRICES for $m \leq (n-1)^2+1$. There are several proofs and extensions of this result (Dulmage and Halperin 1955, Mendelsohn and Dulmage 1958, Mirsky 1958, Marcus 1960).

Dougall-Ramanujan Identity

A hypergeometric identity discovered by Ramanujan around 1910. From Hardy (1999, pp. 13 and 102–03),

$$\sum_{n=0}^{\infty}(-1)^n(s+2n)\frac{s^{(n)}(x+y+z+u+2s+1)^{(n)}}{(x+y+z+u-s)_{(n)}}\prod_{x,y,x,u}\times\frac{x_{(n)}}{(x+s+1)^{(n)}}$$

$$=\frac{s}{\Gamma(s+1)\Gamma(x+y+z+u+s+1)}\prod_{x,y,z,u}\times\frac{\Gamma(x+s+1)\Gamma(y+z+u+s+1)}{\Gamma(z+u+s+1)}. \quad (1)$$

where

$$a^{(n)}\equiv a(a+1)\cdots(a+n-1) \quad (2)$$

is the RISING FACTORIAL (a.k.a. POCHHAMMER SYMBOL,

$$a_{(n)}\equiv a(a-1)\cdots(a-n+1) \quad (3)$$

is the FALLING FACTORIAL (Hardy 1999, p. 101), $\Gamma(z)$ is a GAMMA FUNCTION, and one of

$$x,y,z,u,-x-y-z-u-2s-1 \quad (4)$$

is a POSITIVE INTEGER.

Equation (1) can also be rewritten as

$$ {}_7F_6\left[\begin{matrix}s,1+\frac{1}{2}s,-x,-y,-z,-u,x-y+z+u+2s+1\\ \frac{1}{2}s,x+s+1,y+s+1,z+s+1,u+s+1,\\ -x-y-z-u-s\end{matrix};1\right]$$

$$=\frac{1}{\Gamma(s+1)\Gamma(x+y+z+u+s+1)}\prod_{x,y,z,u}\times\frac{\Gamma(x+s+1)\Gamma(y+z+u+s+1)}{\Gamma(z+u+s+1)}. \quad (5)$$

(Hardy 1999, p. 102). In a more symmetric form, if $n=2a_1+1=a_2+a_3+a_4+a_5$, $a_6=1+a_1/2$, $a_7=-n$, and $b_i=1+a_1-a_{i+1}$ for $i=1, 2, ..., 6$, then

$$ {}_7F_6\left[\begin{matrix}a_1,a_2,a_3,a_4,a_5,a_6,a_7\\ b_1,b_2,b_3,b_4,b_5,b_6\end{matrix};1\right]$$

$$=\frac{(a_1+1)_n(a_1-a_2-a_3+1)_n}{(a_1-a_2+1)_n(a_1-a_3+1)_n}\times\frac{(a_1-a_2-a_4+1)_n(a_1-a_3-a_4+1)_n}{(a_1-a_4+1)_n(a_1-a_2-a_3-a_4+1)_n}, \quad (6)$$

where $(a)_n$ is the POCHHAMMER SYMBOL (Petkovsek *et al.* 1996).

The identity is a special case of JACKSON'S IDENTITY, and gives DIXON'S THEOREM, SAALSCHÜTZ'S THEOREM, and MORLEY'S FORMULA as special cases.

Dovetailing Problem

CUBE DOVETAILING PROBLEM

Dowker Notation

A simple way to describe a knot projection. The advantage of this notation is that it enables a KNOT DIAGRAM to be drawn quickly.

For an oriented ALTERNATING KNOT with n crossings, begin at an arbitrary crossing and label it 1. Now follow the undergoing strand to the next crossing, and denote it 2. Continue around the knot following the same strand until each crossing has been numbered twice. Each crossing will have one even number and one odd number, with the numbers running from 1 to $2n$.

Now write out the ODD NUMBERS 1, 3, ..., $2n-1$ in a row, and underneath write the even crossing number corresponding to each number. The Dowker NOTATION is this bottom row of numbers. When the sequence of even numbers can be broken into two permutations of consecutive sequences (such as $\{4, 6, 2\}\{10, 12, 8\}$), the knot is composite and is not uniquely determined by the Dowker notation. Otherwise, the knot is prime and the NOTATION uniquely defines a single knot (for amphichiral knots) or corresponds to a single knot or its MIRROR IMAGE (for chiral knots).

For general nonalternating knots, the procedure is modified slightly by making the sign of the even numbers POSITIVE if the crossing is on the top strand, and NEGATIVE if it is on the bottom strand.

These data are available for knots, but not for links, from Berkeley's gopher site.

Dragon Curve

Nonintersecting curves which can be iterated to yield more and more sinuosity. They can be constructed by taking a path around a set of dots, representing a left turn by 1 and a right turn by 0. The first-order curve is then denoted 1. For higher order curves, add a 1 to the end, then copy the string of digits preceding it to the end but switching its center digit. For example, the second-order curve is generated as follows: (1)1 → (1)1(0) → 110, and the third as: (110)1 → (110)1(100) → 1101100. Continuing gives 110110011100100... (Sloane's A014577). The OCTAL representation sequence is 1, 6, 154, 66344, ...(Sloane's A003460). The dragon curves of orders 1 to 9 are illustrated below.

This procedure is equivalent to drawing a RIGHT ANGLE and subsequently replacing each RIGHT ANGLE with another smaller RIGHT ANGLE (Gardner 1978). In

fact, the dragon curve can be written as a LINDENMAYER SYSTEM with initial string "FX", STRING REWRITING rules "X" → "X+YF+", "Y" → "−FX-Y", and angle 90°.

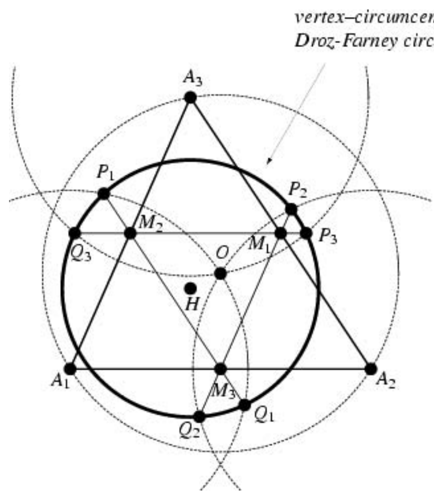
Droz-Farny Circles

The following amazing property of a triangle, first given by Steiner and then proved by Droz-Farny (1901), is related to the so-called Droz-Farny circles. Draw a CIRCLE with center at the ORTHOCENTER H which cuts the lines M_2M_3, M_3M_1, and M_1M_2 (where M_i are the MIDPOINTS of their respective sides) at P_1, Q_1; P_2, Q_2; and P_3, Q_3 respectively, then the line segments $A_iP_i = A_iQ_i$ are all equal:

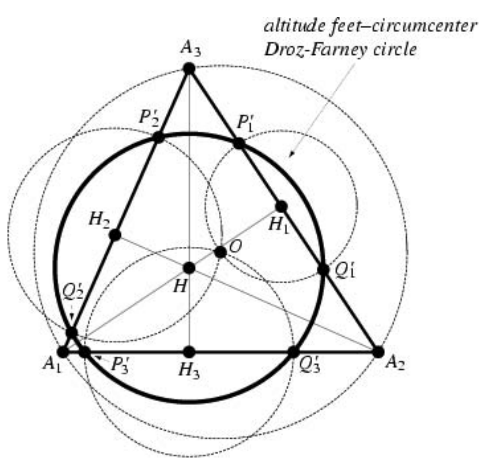


$$A_1P_1 = A_2P_2 = A_3P_3 = A_1Q_1 = A_2Q_2 = A_3Q_3.$$

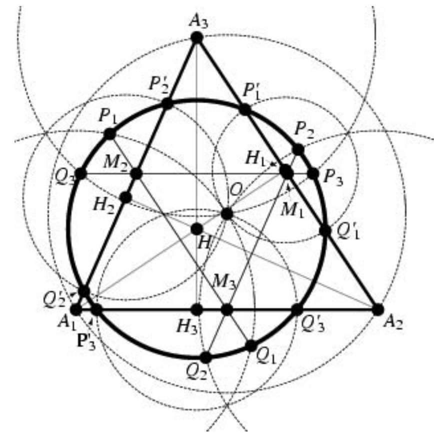
Conversely, if equal CIRCLES are drawn about the VERTICES of a TRIANGLE (dashed circles in the above figure), they cut the lines joining the MIDPOINTS of the corresponding sides in six points P_1, Q_1, P_2, Q_2, P_3, and Q_3, which lie on a CIRCLE whose center is the ORTHOCENTER. If r is the RADIUS of the equal CIRCLES centered on the vertices A_1, A_2, and A_3, and R_0 is the

RADIUS of the CIRCLE about H, then

$$R_0^2 = 4R^2 + r^2 - \frac{1}{2}(a_1^2 + a_2^2 + a_3^2)$$

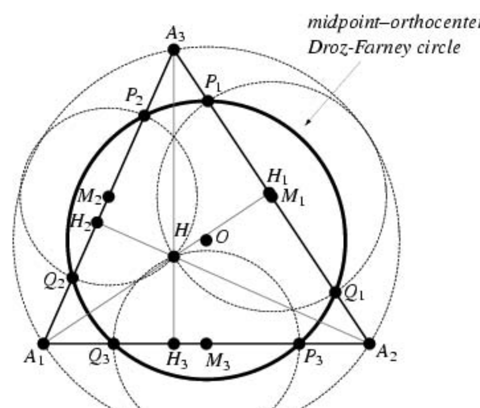


(Johnson 1929, p. 257).



In the special case that r is taken as the CIRCUMRADIUS of the original triangle, then a circle D_1, known as the Droz-Farny circle (in particular, the "vertex-circumcenter Droz-Farny circle"), is obtained, having center H and RADIUS

$$R_0^2 = 5R^2 - \frac{1}{2}(a_1^2 + a_2^2 + a_3^2)$$



(Johnson 1929, pp. 257–78).

The "altitude feet-circumcenter" Droz-Farny circle D_1' is obtained by drawing circles with centers at the feet of the altitudes and passing through the CIRCUMCENTER. These circles cut the corresponding sides in six concyclic points, having *the same center* H and *the same radius* R_0 as the vertex-circumcenter Droz-Farny circle. This is the first Droz-Farny circle.

The first Droz-Farny circle D_1 therefore passes through 12 notable points, two on each of the sides and two on each of the lines joining midpoints of the sides, as illustrated in the rather busy figure above.

The circles about the midpoints of the sides and passing though H cut the sides in six points lying on another circle D_2. This is the second Droz-Farny circle, which has RADIUS equal to that of D_1, but whose center is the CIRCUMCENTER O instead of the ORTHOCENTER H.

There is a beautiful generalization of the Droz-Farny circles motivated by the observation that the ORTHOCENTER and CIRCUMCENTER are ISOGONAL CONJU-

GATES. Let P and Q be any pair of ISOGONAL CONJUGATES of a triangle ΔABC, and let D, E, and F be the feet of the perpendiculars to the sides from one of the points (say, P), and let circles with centers D, E, and F be drawn to pass through Q. Then the three pairs of points on the sides of ΔABC which are determined by these circles always lie on a circle with center P, and the two circles constructed in this way are congruent (Honsberger 1995).

Droz-Farny Theorem

If two perpendicular lines are drawn through the ORTHOCENTER H of any triangle, these lines intercept each side (or its extension) in two points (labeled P_{12}, P'_{12}, P_{13}, P'_{13}, P_{23}, P'_{23}). Then the MIDPOINTS M_{12}, M_{12}, and M_{23} of these three segments are COLLINEAR.

Du Bois Reymond Constants

The constants C_n defined by

$$C_n \equiv \int_0^\infty \left| \frac{d}{dt}\left(\frac{\sin t}{t}\right)^n \right| dt - 1. \quad (1)$$

These constants can also be written as

$$C_n = 2\sum_{k=1}^{\infty} \left(1 + x_k^2\right)^{-n/2}, \quad (2)$$

where x_k is the kth root of

$$t = \tan t. \quad (3)$$

C_1 diverges, and the first few constant are numerically given by

$$C_2 \approx 0.1945280494 \quad (4)$$

$$C_3 \approx 0.028254 \quad (5)$$

$$C_4 \approx 0.005240704678. \quad (6)$$

Rather surprisingly, the even-ordered du Bois Rey-

mond constants (and, in particular, C_2; Le Lionnais 1983) can be computed analytically as polynomials in e^2,

$$C_2 = \frac{1}{2}(e^2 - 7) \tag{7}$$

$$C_4 = \frac{1}{8}(e^4 - 4e^2 - 25) \tag{8}$$

$$C_6 = \frac{1}{32}(e^6 - 6e^4 + 3e^2 - 98). \tag{9}$$

These have the explicit formula

$$C_n = -3 - 2\operatorname*{Res}_{x=i}\left(\frac{x^2}{(1+x^2)^n(\tan x - x)}\right), \tag{10}$$

where n is even and Res denotes a RESIDUE (V. Adamchik).

Dual Basis

Given a CONTRAVARIANT BASIS $\{\vec{e}_1, \ldots, \vec{e}_n\}$, its dual COVARIANT basis is given by

$$\vec{e}^\alpha \cdot \vec{e}\beta = g(\vec{e}^\alpha, \vec{e}\beta) = \delta^\alpha_\beta,$$

where g is the METRIC and δ^α_β is the mixed KRONECKER DELTA. In EUCLIDEAN SPACE with an ORTHONORMAL BASIS,

$$\vec{e}^j = \vec{e}_j,$$

so the BASIS and its dual are the same.

See also DUAL SPACE

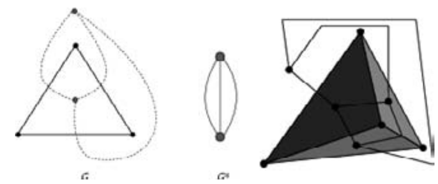
Dual Bivector

A dual BIVECTOR is defined by

$$\tilde{X}_{ab} \equiv \frac{1}{2}\epsilon_{abcd}X^{cd},$$

and a self-dual BIVECTOR by

$$X^*_{ab} \equiv X_{ab} + i\tilde{X}_{ab}.$$



See also BIVECTOR

Dual Bundle

Given a VECTOR BUNDLE $\pi: E \to M$, its dual bundle is a VECTOR BUNDLE $\pi^*: E^* \to M$. The FIBER BUNDLE of E^* over a point $p \in M$ is the DUAL VECTOR SPACE to the fiber of E.

See also DUAL SPACE, VECTOR BUNDLE

Dual Graph

Given a PLANAR GRAPH G, a GEOMETRIC DUAL GRAPH and COMBINATORIAL DUAL GRAPH can be defined. Whitney showed that these are equivalent (Harary 1994), so that one make speak of "the" dual graph G^*. The illustration above shows the process of constructing a GEOMETRIC DUAL GRAPH.

The dual graph G^* of a POLYHEDRAL GRAPH G has VERTICES each of which corresponds to a face of G and each of whose faces corresponds to a VERTEX of G. Two nodes in G^* are connected by an EDGE if the corresponding faces in G have a boundary EDGE in common.

The dual graph of a WHEEL GRAPH is itself a wheel (Skiena 1990, p. 147).

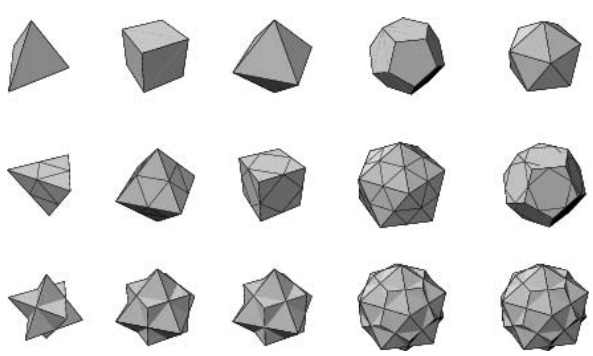
Dual Polyhedron

By the DUALITY PRINCIPLE, for every POLYHEDRON, there exists another POLYHEDRON in which faces and VERTICES occupy complementary locations. This POLY-

HEDRON is known as the dual, or RECIPROCAL. The process of taking the dual is also called RECIPROCATION, or polar reciprocation. Brückner (1900) was among the first to give a precise definition of duality (Wenninger 1983, p. 1).



The dual of a PLATONIC SOLID or ARCHIMEDEAN SOLID can be computed by connecting the midpoints of the sides surrounding each VERTEX (the VERTEX FIGURE; left figure), and constructing the corresponding TANGENTIAL POLYGON (tangent to the CIRCUMCIRCLE of the VERTEX FIGURE; right figure.) This is sometimes called the Dorman-Luke construction (Wenninger 1983, p. 30).

The dual polyhedron of a PLATONIC SOLID or ARCHIMEDEAN SOLID can be also drawn by constructing EDGES tangent to the MIDSPHERE (sometimes also known as the reciprocating sphere or intersphere) which are PERPENDICULAR to the original EDGES. Furthermore, let r be the INRADIUS of the dual polyhedron (corresponding to the INSPHERE, which touches the faces of the dual solid), ρ be the MIDRADIUS of both the polyhedron and its dual (corresponding to the MIDSPHERE, which touches the edges of both the polyhedron and its duals), and R the CIRCUMRADIUS (corresponding to the CIRCUMSPHERE of the solid which touches the vertices of the solid). Since the CIRCUMSPHERE and INSPHERE are dual to each other, r, R, and ρ obey the polar relationship

$$Rr = \rho^2$$

(Cundy and Rollett 1989, Table II following p. 144).

The process of forming duals is illustrated above for the PLATONIC SOLIDS. The top row shows the original solid, the middle row shows the vertex figures of the original solid as lines superposed on the tangential polygons forming the dual faces. The POLYHEDRON COMPOUNDS consisting of a POLYHEDRON and its dual are generally very attractive, and are illustrated in the bottom row.

For an ARCHIMEDEAN SOLID with v vertices, f faces, and e edges, the dual polyhedron has f vertices, v faces, and e edges. The dual of an isogonal solid (i.e., all vertices are alike) is isohedral (i.e., all faces are alike) (Wenninger 1983, p. 5).

The dual of any non-convex UNIFORM POLYHEDRON is a stellated form of the CONVEX HULL of the given polyhedron (Wenninger 1983, pp. 3– and 40).

The following table gives a list of the duals of the PLATONIC SOLIDS and KEPLER-POINSOT SOLIDS, together with the names of the POLYHEDRON-dual COMPOUNDS. (Note that the duals of the PLATONIC SOLIDS are themselves PLATONIC SOLIDS, so no new solids are formed by taking the duals of the Platonic solids.)

Duals can also be taken of other polyhedrons, including the Archimedean solids and Uniform solids. The names of some solids and their duals are given in the table below.

POLYHEDRON	Dual	POLYHEDRON COMPOUND

Dual Scalar

Given a third RANK TENSOR,

$$V_{ijk} \equiv \det[\mathbf{A} \quad \mathbf{B} \quad \mathbf{C}],$$

where det is the DETERMINANT, the dual scalar is defined as

$$V \equiv \frac{1}{3!} \epsilon_{ijk} V_{ijk},$$

where ϵ_{ijk} is the LEVI-CIVITA TENSOR.

See also DUAL TENSOR, LEVI-CIVITA TENSOR

Dual Solid

DUAL POLYHEDRON

Dual Space

The dual space to a real VECTOR SPACE V is the VECTOR SPACE of LINEAR FUNCTIONS $f: V \to \mathbb{R}$, and is denoted V^*. In the dual to a COMPLEX VECTOR SPACE, the linear functions take complex values.

In either case, the dual space has the same DIMENSION as V. Given a BASIS $v_1, \ldots, v_n$ for V there exists a DUAL BASIS for V^*, written $v_1^*, \ldots, v_n^*$, where $v_i^*(v_j) = \delta_{ij}$ and δ_{ij} is the KRONECKER DELTA.

Another way to realize an isomorphism with V is through an INNER PRODUCT. A REAL VECTOR SPACE can have a symmetric INNER PRODUCT $\langle , \rangle$ in which case a vector v corresponds to a dual element by $f_v(w) = \langle w, v \rangle$. Then a basis corresponds to its dual basis only if it is an ORTHONORMAL BASIS, in which case $v_i^* = \langle _, v_i \rangle$. A COMPLEX VECTOR SPACE can have a HERMITIAN INNER PRODUCT, in which case $f_v(w) = \langle w, v \rangle$ is a conjugate-linear isomorphism of V with V^*, i.e., $f_{\alpha v} = \bar{\alpha} f_v$.

Dual spaces can describe many objects in linear algebra. When V and W are finite dimensional vector spaces, an element of the tensor product $V^* \otimes W$, say $\Sigma a_{ij} v_j^* \otimes w_i$, corresponds to the linear transformation $T(v) = \Sigma a_{ij} v_j^*(w) w_i$. That is, $V^* \otimes W \simeq \mathrm{Hom}(V, W)$. For example, the identity transformation is $v_1 \otimes v_1^* + \ldots + v_n \otimes v_n^*$. A BILINEAR FORM on V, such as an inner product, is an element of $V^* \otimes V^*$.

When V is infinite dimensional, care has to be taken of the topology. The dual space of V is the VECTOR SPACE of CONTINUOUS LINEAR FUNCTIONALS on V.

See also BASIS (VECTOR SPACE), BILINEAR FORM, DISTRIBUTION (GENERALIZED FUNCTION), DUAL VECTOR SPACE, LINEAR FUNCTIONAL, MATRIX, SELF-DUAL, VECTOR SPACE

Dual Tensor

Given an antisymmetric second RANK TENSOR C_{ij}, a dual pseudotensor C_i is defined by

$$C_i \equiv \frac{1}{2} \epsilon_{ijk} C_{jk}, \tag{1}$$

where

$$C_i \equiv \begin{bmatrix} C_{23} \\ C_{31} \\ C_{12} \end{bmatrix} \tag{2}$$

$$C_{jk} \equiv \begin{bmatrix} 0 & C_{12} & -C_{31} \\ -C_{12} & 0 & C_{23} \\ C_{31} & -C_{23} & 0 \end{bmatrix}. \tag{3}$$

Dual Tessellation

The dual of a regular TESSELLATION is formed by taking the center of each polygon as a vertex and joining the centers of adjacent polygons.

The triangular and hexagonal tessellations are duals of each other, while the square tessellation it its own dual.

Williams (1979, pp. 37–1) illustrates the dual tessellations of the semiregular tessellations.

Dual Voting

A term in SOCIAL CHOICE THEORY meaning each alternative receives equal weight for a single vote.

See also ANONYMOUS, MONOTONIC VOTING

Duality Principle

All the propositions in PROJECTIVE GEOMETRY occur in dual pairs which have the property that, starting from either proposition of a pair, the other can be immediately inferred by interchanging the parts played by the words "point" and "line." The principle was enunciated by Gergonne (1826; Cremona 1960, p. x). A similar duality exists for RECIPROCATION as first enunciated by Poncelet (1818; Casey 1893; Lachlan 1893; Cremona 1960, p. x).

Example of dual geometric objects include BRIANCHON'S THEOREM and PASCAL'S THEOREM, the 15 PLÜCKER LINES and 15 SALMON POINTS, the 20 CAYLEY LINES and 20 STEINER POINTS, the 60 PASCAL LINES and 60 KIRKMAN POINTS, DUAL POLYHEDRA, and DUAL TESSELLATIONS.

Propositions which are equivalent to their duals are said to be SELF-DUAL.

See also BRIANCHON'S THEOREM, CONSERVATION OF NUMBER PRINCIPLE, DESARGUES' THEOREM, DUAL POLYHEDRON, PAPPUS'S HEXAGON THEOREM, PASCAL'S THEOREM, PERMANENCE OF MATHEMATICAL RELATIONS PRINCIPLE, PROJECTIVE GEOMETRY, RECIPROCAL, RECIPROCATION, SELF-DUAL

Duality Theorem

Dual pairs of LINEAR PROGRAMS are in "strong duality" if both are possible. The theorem was first conceived by John von Neumann. The first written proof was an Air Force report by George Dantzig, but credit is usually given to Tucker, Kuhn, and Gale.

See also LINEAR PROGRAMMING

Duffing Differential Equation

The most general forced form of the Duffing equation is

$$\ddot{x}+\delta\dot{x}+\left(\beta x^3\pm\omega_0^2x\right)=A\sin(\omega t+\phi). \tag{1}$$

If there is no forcing, the right side vanishes, leaving

$$\ddot{x}+\delta\dot{x}+\left(\beta x^3\pm\omega_0^2x\right)=0. \tag{2}$$

If $\delta=0$ and we take the plus sign,

$$\ddot{x}+\omega_0^2x+\beta x^3=0 \tag{3}$$

(Bender and Orszag 1978, p. 547; Zwillinger 1997, p. 122).

This equation can display chaotic behavior. For $\beta>0$, the equation represents a "hard spring," and for $\beta<0$, it represents a "soft spring." If $\beta<0$, the phase portrait curves are closed. Returning to (1), take $\beta=1$, $\omega_0=1$, $A=0$, and use the minus sign. Then the equation is

$$\dot{x}+\delta\dot{x}+\left(x^3-x\right)=0 \tag{4}$$

(Ott 1993, p. 3). This can be written as a system of first-order ordinary differential equations by writing

$$\dot{x}=y, \tag{5}$$

$$\dot{y}=x-x^3-\delta y. \tag{6}$$

The fixed points of these differential equations

$$\dot{x}=y=0, \tag{7}$$

so $y=0$, and

$$\dot{y}=x-x^3-\delta y=x\left(1-x^2\right)-0 \tag{8}$$

giving $x=0,\pm1$. Differentiating,

$$\ddot{x}=\dot{y}=x-x^3-\delta y \tag{9}$$

$$\ddot{y}=\left(1-3x^2\right)\dot{x}-\delta\dot{y} \tag{10}$$

$$\begin{bmatrix}\ddot{x}\\ \ddot{y}\end{bmatrix}=\begin{bmatrix}0 & 1\\ 1-3x^2 & -\delta\end{bmatrix}\begin{bmatrix}\dot{x}\\ \dot{y}\end{bmatrix}. \tag{11}$$

Examine the stability of the point (0,0):

$$\begin{vmatrix}0-\lambda & 1\\ 1 & -\delta-\lambda\end{vmatrix}=\lambda(\lambda+\delta)-1=\lambda^2+\lambda\delta-1=0 \tag{12}$$

$$\lambda_\pm^{(0,0)}=\frac{1}{2}\left(-\delta\pm\sqrt{\delta^2+4}\right). \tag{13}$$

But $\delta^2\geq0$, so $\lambda_\pm^{(0,0)}$ is real. Since $\sqrt{\delta^2+4}>|\delta|$, there will always be one POSITIVE ROOT, so this fixed point is unstable. Now look at $(\pm1,0)$.

$$\begin{vmatrix}0-\lambda & 1\\ -2 & -\delta-\lambda\end{vmatrix}=\lambda(\lambda+\delta)+2=\lambda^2+\lambda\delta+2=0 \tag{14}$$

$$\lambda_\pm^{(\pm1,0)}=\frac{1}{2}\left(-\delta\pm\sqrt{\delta^2-8}\right). \tag{15}$$

For $\delta>0$, $\Re\left[\lambda_\pm^{(\pm1,0)}\right]<0$, so the point is asymptotically stable. If $\delta=0$, $\lambda_+^{(\pm1,0)}=\pm i\sqrt{2}$, so the point is linearly stable. If $\delta\in(-2\sqrt{2},0)$, the radical gives an IMAGINARY PART and the REAL PART is >0, so the point is unstable. If $\delta=-2\sqrt{2}$, $\lambda_\pm^{(\pm1,0)}=\sqrt{2}$, which has a POSITIVE REAL ROOT, so the point is unstable. If $\delta<-2\sqrt{2}$, then $|\delta|<\sqrt{\delta^2-8}$, so both ROOTS are POSITIVE and the point is unstable. The following table summarizes these results.

$\delta>0$	asymptotically stable
$\delta=0$	linearly stable (superstable)
$\delta<0$	unstable

Now specialize to the case $\delta=0$, which can be integrated by quadratures. In this case, the equations become

$$\dot{x}=y \tag{16}$$

$$\dot{y}=x-x^3. \tag{17}$$

Differentiating (16) and plugging in (17) gives

$$\ddot{x}=\dot{y}=x-x^3. \tag{18}$$

Multiplying both sides by $\dot{x}$ gives

$$\ddot{x}\dot{x}-\dot{x}x+\dot{x}x^3=0 \tag{19}$$

$$\frac{d}{dt}\left(\frac{1}{2}\dot{x}^2-\frac{1}{2}x^2-\frac{1}{4}x^4\right)=0, \tag{20}$$

so we have an invariant of motion h,

$$h\equiv\frac{1}{2}\dot{x}^2-\frac{1}{2}x+\frac{1}{4}x^4. \tag{21}$$

Solving for $\dot{x}^2$ gives

$$\dot{x}^2 = \left(\frac{dx}{dt}\right)^2 = 2h + x^2 - \frac{1}{2}x^4, \tag{22}$$

$$\frac{dx}{dt} = \sqrt{2h + x^2 + \frac{1}{2}x^2}, \tag{23}$$

so

$$t = \int dt = \int \frac{dx}{\sqrt{2h + x^2 + \frac{1}{2}x^2}}. \tag{24}$$

Note that the invariant of motion h satisfies

$$\dot{x} = \frac{\partial h}{\partial \dot{x}} = \frac{\partial h}{\partial y} \tag{25}$$

$$\frac{\partial h}{\partial x} = -x + x^3 = -\dot{y}, \tag{26}$$

so the equations of the Duffing oscillator are given by the Hamiltonian system

$$\begin{cases} \dot{x} = \dfrac{\partial h}{\partial y} \\ \dot{y} = -\dfrac{\partial h}{\partial x}. \end{cases} \tag{27}$$

Dummy Variable

A variable that appears in a calculation only as a placeholder and which disappears completely in the final result. For example, in the integral

$$\int_0^x f(x')dx',$$

x' is a dummy variable since it is "integrated out" in the final answer. Any variable name other than x could therefore be used in the above expression, e.g. $\int_0^x f(\lambda)d\lambda$, $\int_0^x f(q)dq$, etc.

Dummy variables are also called bound variables or dead variables. Comtet (1974) adopts a notation in which dummy variable appearing as indices in sums are denoted by placing a dot underneath them (i.e., indicating them with an underdot), e.g.,

$$\sum_{\underset{.}{c}_1 + \underset{.}{c}_2 = n} c_1 c_2 = \frac{1}{6} n(n^2 - 1)$$

(Comtet 1974, p. 33).

Dupin's Cyclide

CYCLIDE

Dupin's Indicatrix

A pair of conics obtained by expanding an equation in MONGE'S FORM $z=F(x,y)$ in a MACLAURIN SERIES

$$z=z(0,0)+z_1x+z_2y+\frac{1}{2}(z_{11}x^2+2z_{12}xy+z_{22}y^2)+\ldots$$

$$=\frac{1}{2}(b_{11}x^2+2b_{12}xy+b_{22}y^2).$$

This gives the equation

$$b_{11}x^2+2b_{12}xy+b_{22}y^2=\pm 1.$$

Amazingly, the radius of the indicatrix in any direction is equal to the SQUARE ROOT of the RADIUS OF CURVATURE in that direction (Coxeter 1969).

Dürer's Conchoid

These curves appear in Dürer's work *Instruction in Measurement with Compasses and Straight Edge* (1525) and arose in investigations of perspective. Dürer constructed the curve by drawing lines QRP and $P'QR$ of length 16 units through $Q(q,0)$ and $R(r,0)$, where $q+r=13$. The locus of P and P' is the

curve, although Dürer found only one of the two branches of the curve.

The ENVELOPE of the lines QRP and $P'QR$ is a PARABOLA, and the curve is therefore a GLISSETTE of a point on a line segment sliding between a PARABOLA and one of its TANGENTS.

Dürer called the curve "muschellini," which means CONCHOID. However, it is not a true CONCHOID and so is sometimes called DÜRER'S SHELL CURVE. The Cartesian equation is

$$2y^2(x^2+y^2)-2by^2(x+y)+(b^2-3a^2)y^2-a^2x^2$$
$$+2a^2b(x+y)+a^2(a^2-b^2)=0.$$

The above curves are for $(a,b)=(3,1)$, $(3,3)$, $(3,5)$. There are a number of interesting special cases. If $b=0$, the curve becomes two coincident straight lines $x=0$. For $a=0$, the curve becomes the line pair $x=b/2$, $x=-b/2$, together with the CIRCLE $x+y=b$. If $a=b/2$, the curve has a CUSP at $(-2a,a)$.

Dürer's Magic Square

16	3	2	13
5	10	11	8
9	6	7	12
4	15	14	1

Dürer's magic square is a MAGIC SQUARE with MAGIC CONSTANT 34 used in an engraving entitled *Melencolia I* by Albrecht Dürer (The British Museum, Burton 1989, Gellert *et al.* 1989). The engraving shows a disorganized jumble of scientific equipment lying unused while an intellectual sits absorbed in thought. Dürer's magic square is located in the upper right-hand corner of the engraving. The numbers 15 and 14 appear in the middle of the bottom row, indicating the date of the engraving, 1514.

Dürer's Shell Curve

DÜRER'S CONCHOID

Dürer's Solid

The 8-faced solid depicted in an engraving entitled *Melencolia I* by Albrecht Dürer (The British Museum, Burton 1989, Gellert *et al.* 1989), the same engraving in which DÜRER'S MAGIC SQUARE appears, which depicts a disorganized jumble of scientific equipment lying unused while an intellectual sits absorbed in thought. Although Dürer does not specify how his solid is constructed, Schreiber (1999) has noted that it appears to consist of a distorted CUBE which is first stretched to give rhombic faces with angles of 72°, and then truncated on top and bottom to yield bounding triangular faces whose vertices lie on the CIRCUMSPHERE of the azimuthal cube vertices.

Starting with a unit cube oriented parallel to the axes of the coordinate system, rotate it by EULER ANGLES $\psi=\pi/4$ and $\theta=\sec^{-1}\sqrt{3}$ to align a threefold symmetry axis along the z-axis. The stretch factor needed to produce rhombic angles of 72° is then

$$s = \sqrt{1 + \frac{3}{\sqrt{5}}}. \quad (1)$$

The azimuthal points are a distance $d = s/2$ away from the origin, and in order for the vertices of the triangles obtained by truncation to lie at this same distance, the TRUNCATION must be done a distance $(3 - \sqrt{5})/2$ along the edge from one of the azimuthal points, which corresponds to a height

$$h = \sqrt{\frac{23}{\sqrt{5}} - \frac{1}{4}}. \quad (2)$$

The resulting solid has six 126–08–2–08–26° pentagonal faces and two equilateral triangular faces, and the lengths of the sides are in the ratio

$$1 : \tfrac{1}{2}(3 + \sqrt{5}) : \sqrt{\tfrac{1}{2}(5 + \sqrt{5})}. \quad (3)$$

Examination of this solid shows it to be identical to the dimensions of the solid reconstructed from its perspective picture (Schröder 1980, p. 70; Schreiber 1999).

Dust

CANTOR DUST, FATOU DUST

Dvoretzky's Theorem

Each centered convex body of sufficiently high dimension has an "almost spherical" k-dimensional central section.

Dyad

Dyads extend VECTORS to provide an alternative description to second RANK TENSORS. A dyad $D(\mathbf{A}, \mathbf{B})$ of a pair of VECTORS $\mathbf{A}$ and $\mathbf{B}$ is defined by $D(\mathbf{A}, \mathbf{B}) \equiv \mathbf{AB}$. The DOT PRODUCT is defined by

$$\mathbf{A}.\mathbf{BC} \equiv (\mathbf{A}.\mathbf{B})\mathbf{C}$$

$$\mathbf{AB}.\mathbf{C} \equiv \mathbf{A}(\mathbf{B}.\mathbf{C}),$$

and the COLON PRODUCT by

$$\mathbf{AB} : \mathbf{CD} \equiv \mathbf{C}.\mathbf{AB}.\mathbf{D} = (\mathbf{A}.\mathbf{C})(\mathbf{B}.\mathbf{D})$$

See also DYADIC, TENSOR

References

Morse, P. M. and Feshbach, H. "Dyadics and Other Vector Operators." §1.6 in *Methods of Theoretical Physics, Part I.* New York: McGraw-Hill, pp. 54–2, 1953.

Dyadic

A linear POLYNOMIAL of DYADS $\mathbf{AB}+\mathbf{CD}+\ldots$ consisting of nine components A_{ij} which transform as

$$(A_{ij})' = \sum_{m,n} \frac{h_m h_n}{h_i' h_j'} \frac{\partial x_m}{\partial x_i'} \frac{\partial x_n}{\partial x_j'} A_{mn} \qquad (1)$$

$$= \sum_{m,n} \frac{h_i' h_j'}{h_m h_n} \frac{\partial x_i'}{\partial x_m} \frac{\partial x_j}{\partial x_n} A_{mn} \qquad (2)$$

$$= \sum_{m,n} \frac{h_i' h_n}{h_m h_j'} \frac{\partial x_i'}{\partial x_m} \frac{\partial x_m}{\partial x_j'} Amn. \qquad (3)$$

Dyadics are often represented by Gothic capital letters. The use of dyadics is nearly archaic since TENSORS perform the same function but are notationally simpler.

A unit dyadic is also called the IDEMFACTOR and is defined such that

$$\mathbf{I}.\mathbf{A} \equiv \mathbf{A}. \qquad (4)$$

In CARTESIAN COORDINATES,

$$\mathbf{I} = \hat{\mathbf{x}}\hat{\mathbf{x}} + \hat{\mathbf{y}}\hat{\mathbf{y}} + \hat{\mathbf{z}}\hat{\mathbf{z}}, \qquad (5)$$

and in SPHERICAL COORDINATES

$$\mathbf{I} = \nabla \mathbf{r}. \qquad (6)$$

Dynamical System

A means of describing how one state develops into another state over the course of time. Technically, a dynamical system is a smooth action of the reals or the INTEGERS on another object (usually a MANIFOLD). When the reals are acting, the system is called a continuous dynamical system, and when the INTEGERS are acting, the system is called a discrete dynamical system. If f is any CONTINUOUS FUNCTION, then the evolution of a variable x can be given by the formula

$$x_{n+1} = f(x_n). \tag{1}$$

This equation can also be viewed as a difference equation

$$x_{n+1} - x_n = f(x_n) - x_n, \tag{2}$$

so defining

$$g(x) \equiv f(x) - x \tag{3}$$

gives

$$x_{n+1} - x_n = g(x_n) * 1, \tag{4}$$

which can be read "as n changes by 1 unit, x changes by $g(x)$." This is the discrete analog of the DIFFERENTIAL EQUATION

$$x'(n) = g(x(n)). \tag{5}$$

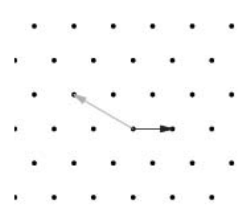
Dynkin Diagram



Every SEMISIMPLE LIE ALGEBRA $\mathfrak{g}$ is classified by its Dynkin diagram. A Dynkin diagram is a GRAPH with a few different kinds of possible edges. The CONNECTED COMPONENTS of the graph correspond to the irreducible subalgebras of $\mathfrak{g}$. So a SIMPLE LIE ALGEBRA's Dynkin diagram has only one component. The rules are restrictive. In fact, there are only certain possibilities for each component, corresponding to the classification of SEMI-SIMPLE LIE ALGEBRAS.

The roots of a complex LIE ALGEBRA form a LATTICE of rank k in a CARTAN SUBALGEBRA $\mathrm{h} \subset \mathfrak{g}$, where k is the RANK of $\mathfrak{g}$. Hence, the ROOT LATTICE can be considered a lattice in $\mathbb{R}^k$. A vertex, or node, in the Dynkin diagram is drawn for each SIMPLE ROOT, which corresponds to a generator of the ROOT LATTICE. Between two nodes α and β, an edge is drawn if the simple roots are not perpendicular. One line is drawn if the angle between them is $2\pi/3$, two lines if the angle is $3\pi/3$, and three lines are drawn if the angle is $5\pi/6$. There are no other possible angles between SIMPLE ROOTS. Alternatively, the number of lines N between the simple roots α and β is given by

$$N = A_{\alpha\beta} A_{\beta\alpha} = \frac{2\langle\alpha, \beta\rangle}{|\alpha|^2} \frac{2\langle\beta, \alpha\rangle}{|\beta|^2} = 4\cos^2\theta,$$

where $A_{\alpha\beta}$ is an entry in the CARTAN MATRIX. In a Dynkin diagram, an arrow is drawn from the longer root to the shorter root (when the angle is $3\pi/3$ or $5\pi/6$).

The picture above shows the two simple roots for G_2, at an angle of $5\pi/6$, in the ROOT LATTICE. Therefore, the Dynkin diagram for G_2 has two nodes, with three lines between them.

Here are some properties of admissible Dynkin diagrams.

1. A diagram obtained by removing a node from an admissible node is admissible.
2. An admissible diagram has no loops.
3. No node has more than three lines attached to it.
4. A sequence of nodes with only two single lines can be collapsed to give an admissible diagram.
5. The only connected diagram with a triple line has two nodes.

A COXETER-DYNKIN DIAGRAM, also called a Coxeter graph, is the same as a Dynkin diagram, without the arrows, although sometimes these are also called Dynkin diagrams. The Coxeter diagram is sufficient to characterize the algebra, as can be seen by enumerating connected diagrams.

The simplest way to recover a SIMPLE LIE ALGEBRA from its Dynkin diagram is to first reconstruct its CARTAN MATRIX (A_{ij}). The ith node and jth node are connected by $A_{ij}A_{ji}$ lines. Since $A_{ij}=0$ IFF $A_{ji}=0$, and otherwise $A_{ji}\in\{-3,-2,-1\}$, it is easy to find A_{ij} and A_{ji}, up to order, from their product. The arrow in the diagram indicates which is larger. For example, if node 1 and node 2 have two lines between them, from node 1 to node 2, then $A_{12}=-1$ and $A_{21}=-2$.

However, it is worth pointing out that each SIMPLE LIE ALGEBRA can be constructed concretely. For instance, the infinite families A_n, B_n, C_n, and D_n correspond to $\mathfrak{sl}_{n+1}\mathbb{C}$ the SPECIAL LINEAR LIE ALGEBRA, $\mathfrak{so}_{2n+1}\mathbb{C}$ the odd ORTHOGONAL LIE ALGEBRA, $\mathfrak{sp}_{2n}\mathbb{C}$ the SYMPLECTIC LIE ALGEBRA, and $\mathfrak{so}_{2n}\mathbb{C}$ the even ORTHOGONAL LIE ALGEBRA. The other simple Lie algebras are called EXCEPTIONAL LIE ALGEBRAS, and have constructions related to the OCTONIONS.

Dyson's Conjecture

Based on a problem in particle physics, Dyson (1962abc) conjectured that the constant term in the LAURENT SERIES

$$\prod_{1\le i\ne j\le n}\left(1-\frac{x_i}{x_j}\right)^{a_i}$$

is the MULTINOMIAL COEFFICIENT

$$\frac{(a_1+a_2+\ldots+a_n)}{a_1!a_2!\ldots a_n!}$$

The theorem was proved by Wilson (1962) and independently by Gunson (1962). A definitive proof was subsequently published by Good (1970).

E

Ear

A PRINCIPAL VERTEX x_i of a SIMPLE POLYGON P is called an ear if the diagonal $[x_{i-1}, x_{i+1}]$ that bridges x_i lies entirely in P. Two ears x_i and x_j are said to overlap if

$$\text{int}[x_{i-1}, x_i, x_{i+1}] \cap \text{int}[x_{j-1}, x_j, x_{j+1}] \neq \emptyset.$$

The TWO-EARS THEOREM states that, except for TRIANGLES, every SIMPLE POLYGON has at least two nonoverlapping ears.

Early Election Results

Let Jones and Smith be the only two contestants in an election that will end in a deadlock when all votes for Jones (J) and Smith (S) are counted. What is the EXPECTATION VALUE of $X_k \equiv |S - J|$ after k votes are counted? The solution is

$$\langle X_k \rangle = \frac{2N\binom{N-1}{\lfloor k/2 \rfloor}\binom{N-1}{\lfloor k/2 \rfloor - 1}}{\binom{2N}{k}}$$

$$= \begin{cases} \dfrac{k(2N-k)}{2N}\dbinom{N}{k/2}^2\dbinom{2N}{k}^{-1} \\ \text{for } k \text{ even} \\ \dfrac{k(2N-k+1)}{2N}\dbinom{N}{(k-1)/2}^2\dbinom{2N}{k-1}^{-1} \\ \text{for } k \text{ odd.} \end{cases}$$

Eban Number

The sequence of numbers whose names (in English) do not contain the letter "e" (i.e., "e" is "banned"). The first few eban numbers are 2, 4, 6, 30, 32, 34, 36, 40, 42, 44, 46, 50, 52, 54, 56, 60, 62, 64, 66, 2000, 2002, 2004, ... (Sloane's A006933); i.e., two, four, six, thirty, etc.

Eberhart's Conjecture

If q_n is the nth prime such that M_{q_n} is a MERSENNE PRIME, then

$$q_n \sim (3/2)^n.$$

It was modified by Wagstaff (1983) to yield WAGSTAFF'S CONJECTURE,

$$q_n \sim (2^{e^{-\gamma}})^n,$$

where γ is the EULER-MASCHERONI CONSTANT.

See also WAGSTAFF'S CONJECTURE

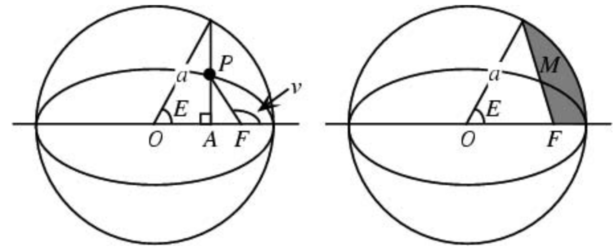
Eccentric

Not CONCENTRIC.



See also CONCENTRIC, CONCYCLIC

Eccentric Angle

The angle θ measured from the CENTER of an ELLIPSE to a point on the ELLIPSE.

See also ECCENTRICITY, ELLIPSE

Eccentric Anomaly

The ANGLE obtained by drawing the AUXILIARY CIRCLE of an ELLIPSE with center O and FOCUS F, and drawing a LINE PERPENDICULAR to the SEMIMAJOR AXIS and intersecting it at A. The ANGLE E is then defined as illustrated above. Then for an ELLIPSE with ECCENTRICITY e,

$$AF = OF - AO = ae - a\cos E \tag{1}$$

But the distance AF is also given in terms of the distance from the FOCUS $r = FP$ and the SUPPLEMENT of the ANGLE from the SEMIMAJOR AXIS v by

$$AF = r\cos(\pi - v) = -r\cos v. \tag{2}$$

Equating these two expressions gives

$$r = \frac{a(\cos E - e)}{\cos v}, \tag{3}$$

which can be solved for $\cos v$ to obtain

$$\cos v = \frac{a(\cos E - e)}{r}. \tag{4}$$

To get E in terms of r, plug (4) into the equation of the ELLIPSE

$$r = \frac{a(1 - e^2)}{1 + \cos v}. \tag{5}$$

Rearranging,

$$r(1 + e \cos v) = a(1 - e^2) \tag{6}$$

and plugging in (4) then gives

$$\begin{aligned} r\left(1 + \frac{ae \cos E}{r} - \frac{e^2}{r}\right) &= r + ae \cos E - e^2 a \\ &= a(1 - e^2). \end{aligned} \tag{7}$$

Solving for r gives

$$r = a(1 - e^2) - ea \cos E + e^2 a = a(1 - e \cos E), \tag{8}$$

so differentiating yields the result

$$\dot{r} = ae\dot{E} \sin E. \tag{9}$$

The eccentric anomaly is a very useful concept in orbital mechanics, where it is related to the so-called mean anomaly M by KEPLER'S EQUATION

$$M = E - e \sin E. \tag{10}$$

M can also be interpreted as the AREA of the shaded region in the above figure (Finch).

See also ECCENTRICITY, ELLIPSE, KEPLER'S EQUATION

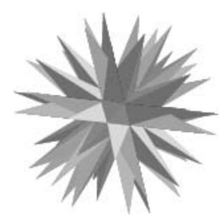
Eccentricity

A quantity defined for a CONIC SECTION which can be given in terms of SEMIMAJOR a and SEMIMINOR AXES b.

interval	curve	e
$e = 0$	CIRCLE	0
$0 < e < 1$	ELLIPSE	$\sqrt{1 - \frac{b^2}{a^2}}$
$e = 1$	PARABOLA	1
$e > 1$	HYPERBOLA	$\sqrt{1 + \frac{b^2}{a^2}}$



The eccentricity can also be interpreted as the fraction of the distance to the semimajor axis at which the FOCUS lies,

$$e = \frac{c}{a},$$

where c is the distance from the center of the CONIC SECTION to the FOCUS.

See also CIRCLE, CONIC SECTION, ECCENTRIC ANOMALY, ELLIPSE, FLATTENING, FOCAL PARAMETER, HYPERBOLA, PARABOLA, SEMIMAJOR AXIS, SEMIMINOR AXIS

Eckert IV Projection

The equations are

$$x = \frac{2}{\sqrt{\pi(4+\pi)}}(\lambda - \lambda_0)(1+\cos\theta) \quad (1)$$

$$y = 2\sqrt{\frac{\pi}{4+\pi}}\sin\theta, \quad (2)$$

where θ is the solution to

$$\theta + \sin\theta\cos\theta + 2\sin\theta = (2 + \tfrac{1}{2}\pi)\sin\phi. \quad (3)$$

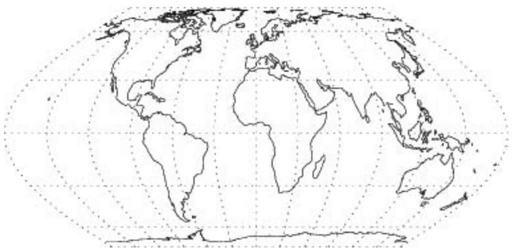
This can be solved iteratively using NEWTON'S METHOD with $\theta_0 = \phi/2$ to obtain

$$\Delta\theta = -\frac{\theta + \sin\theta\cos\theta + 2\sin\theta - (2 - \frac{1}{2}\pi)\sin\phi}{2\cos\theta(1+\cos\theta)}. \quad (4)$$

The inverse FORMULAS are

$$\phi = \sin^{-1}\left(\frac{\theta + \sin\theta\cos\theta + 2\sin\theta}{2+\frac{1}{2}\pi}\right) \quad (5)$$

$$\lambda = \lambda_0 + \frac{\pi\sqrt{4+\pi}\,x}{1+\cos\theta}, \quad (6)$$



where

$$\theta = \sin^{-1}\left(\frac{y}{2}\sqrt{\frac{4+\pi}{\pi}}\right). \quad (7)$$

Economical Number

A number n is called an economical number if the number of digits in the prime factorization of n (including powers) uses fewer digits than the number of digits in n. The first few economical numbers are 125, 128, 243, 256, 343, 512, 625, 729, ... (Sloane's A046759). Pinch shows that, under a plausible hypothesis related to the TWIN PRIME CONJECTURE, there are arbitrarily long sequences of consecutive economical numbers, and exhibits such a sequence of length nine starting at 1034429177995381247.

Edge (Graph)

For an undirected graph, an unordered pair of nodes which specify the line connecting them are said to form an edge. For a directed graph, the edge is an ordered pair of nodes. The terms "line," "arc," "branch," and "1-simplex" are sometimes used instead of edge (Skiena 1990, p. 80; Harary 1994). Harary (1994) calls an edge of a graph a "line."

Edge (Polygon)

A line segment on the boundary of a face, also called a side.

See also Edge (Polyhedron), Vertex (Polygon)

Edge (Polyhedron)

A line segment where two faces of a polyhedron meet, also called a side.

See also Edge (Polygon), Vertex (Polyhedron)

Edge (Polytope)

A 1-D line segment where two 2-D faces of an n-D polytope meet, also called a side.

See also Edge (Polygon), Edge (Polyhedron)

Edge Chromatic Number

The fewest number of colors necessary to color each edge of a graph so that no two edges incident on the same vertex have the same color. The edge chromatic number of a graph must be at least Δ, the largest vertex degree of the graph (Skiena 1990, p. 216). However, Vizing (1964) and Gupta (1966) showed that any graph can be edge-colored with at most $\Delta+1$ colors.

The edge chromatic number of a complete bipartite graph is Δ.

Determining the edge chromatic number of a graph is an NP-complete problem (Holyer 1981; Skiena 1990, p. 216). The edge chromatic number of a graph can be computed using `EdgeChromaticNumber[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Edge Coloring

An edge coloring of a GRAPH G is a coloring of the edges of G such that adjacent edges (or the edges bounding different regions) receive different colors. BRELAZ'S HEURISTIC ALGORITHM can be used to find a good, but not necessarily minimal, edge coloring. Finding the minimum vertex coloring is equivalent to finding the minimum VERTEX COLORING of its LINE GRAPH (Skiena 1990, p. 216). The EDGE CHROMATIC NUMBER gives the minimum number of colors with which a graph can be colored.

An edge coloring of a graph can be computed using `EdgeColoring[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Edge Connectivity

The minimum number of edges $\lambda(G)$ whose deletion from a GRAPH G disconnects G, also called the line connectivity. The edge connectivity of a DISCONNECTED GRAPH is 0, while that of a CONNECTED GRAPH with a BRIDGE is 1.

Let $\kappa(G)$ be the VERTEX CONNECTIVITY of a graph G and $\delta(G)$ its minimum degree, then for any graph,

$$\kappa(G) \le \lambda(G) \le \delta(G)$$

(Whitney 1932, Harary 1994, p. 43).

The edge-connectivity of a graph can be determined with the command `EdgeConnectivity[g]` in the *Mathematica* add-on package `DiscreteMath`Combinatorica`` (which can be loaded with the command `<<DiscreteMath``).

Edgeworth Series

Let a distribution to be approximated be the distribution F_n of standardized sums

$$Y_n = \frac{\sum_{i=1}^n (X_i - \bar{X})}{\sqrt{\sum_{i=1}^n \sigma_X^2}}. \quad (1)$$

In the CHARLIER SERIES, take the component random variables identically distributed with mean μ, variance σ^2, and higher cumulants $\sigma^r \lambda_r$ for $r \geq 3$. Also, take the developing function $\Psi(t)$ as the standard NORMAL DISTRIBUTION FUNCTION $\Phi(t)$, so we have

$$\kappa_1 - \gamma_1 = 0 \quad (2)$$

$$\kappa_2 - \gamma_2 = 0 \quad (3)$$

$$\kappa_3 - \gamma_3 = \frac{\lambda^r}{n^{r/2-1}}. \quad (4)$$

Then the Edgeworth series is obtained by collecting terms to obtain the asymptotic expansion of the CHARACTERISTIC FUNCTION (PROBABILITY) OF THE FORM

$$f_n(t) = \left[1 + \sum_{r=1}^{\infty} \frac{P_r(it)}{n^{r/2}}\right] e^{-t^2/2}, \quad (5)$$

where P_r is a polynomial of degree $3r$ with coefficients depending on the cumulants of orders 3 to $r+2$. If the powers of Ψ are interpreted as derivatives, then the distribution function expansion is given by

$$F_n(x) = \Psi(x) + \sum_{r=1}^{\infty} \frac{P_r(-\Phi(x))}{n^{r/2}} \quad (6)$$

(Wallace 1958). The first few terms of this expansion are then given by

$$f(t) = \Psi(t) - \frac{\lambda_3 \Psi^{(3)}(t)}{6\sqrt{n}} + \frac{1}{n}\left[\frac{\lambda_4 \Psi^{(4)}(t)}{24} + \frac{\lambda_3^2 \Psi^{(6)}(t)}{72}\right] + \ldots \quad (7)$$

Cramér (1928) proved that this series is uniformly valid in t.

e-Divisor

d is called an e-divisor (or exponential divisor) of a number n with PRIME FACTORIZATION

$$n = p_1^{a_1} p_2^{a_2} \cdots p_r^{a_r}$$

if $d|n$ and

$$d = p_1^{b_1} p_2^{b_2} \cdots p_r^{b_r},$$

where $b_j | a_j$ for $1 \leq j \leq r$. For example, the e-divisors of 36 are $2 \cdot 3$, $4 \cdot 3$, $2 \cdot 9$, and $4 \cdot 9$.

Edmonds' Map

A nonreflexible regular map of GENUS 7 with eight VERTICES, 28 EDGES, and eight HEPTAGONAL faces.

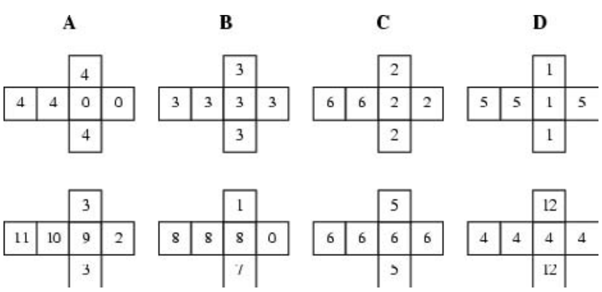
Effective Action

A GROUP ACTION $G \times X \to X$ is effective if there are no nontrivial actions. In particular, this means that there is no element of the GROUP (besides the

IDENTITY ELEMENT) which does nothing, leaving every point where it is. This can be expressed as $\cap_{x \in X} G_x = \{e\}$, where G_x is the ISOTROPY GROUP at x and e is the identity of G.

It is possible for a LIE GROUP G to have an effective action on a smaller dimensional space M. However,

$$N(M) = \max\{\dim G | G \text{ is a compact Lie group, acting effectively on } M\}$$



is finite, and is called the degree of symmetry of M.

E-Function

For any $\alpha \in \mathbb{A}$ (where $\mathbb{A}$ denotes the set of ALGEBRAIC NUMBERS), let $\overline{|\alpha|}$ denote the maximum of moduli of all conjugates of α. Then a function

$$f(z) = \sum_{n=0}^{\infty} c_n \frac{z^n}{n!}$$

is said to be an E-function if the following conditions hold (Nesterenko 1999).

1. All coefficients c_n belong to the same ALGEBRAIC NUMBER FIELD K of finite degree over $\mathbb{Q}$.
2. If $\epsilon > 0$ is any positive number, then $\overline{|c_n|} = \mathcal{O}(n^{\epsilon n})$ as $n \to \infty$.
3. For any $\epsilon > 0$, there exists a sequence of natural numbers $\{q_n\}_{n \geq 1}$ such that $q_n c_k \in \mathbb{Z}_K$ for $k = 0, \ldots, n$ and that $q_n = \mathcal{O}(n^{\epsilon n})$.

Every E-function is an ENTIRE FUNCTION, and the set of E-functions is a RING under the operations of ADDITION and MULTIPLICATION. Furthermore, if $f(z)$ is an E-function, then $f'(z)$ and $\int_0^z f(t)\,dt$ are E-functions, and for any ALGEBRAIC NUMBER α, the function $f(\alpha z)$ is also an E-function (Nesterenko 1999).

Egyptian Fraction

EGYPTIAN NUMBER, UNIT FRACTION

Egyptian Number

A number n is called an Egyptian number if it is the sum of the DENOMINATORS in some UNIT FRACTION representation of a positive whole number not consisting entirely of 1s. For example,

$$1 = \frac{1}{2} + \frac{1}{3} + \frac{1}{6},$$

so $2 + 3 + 6 = 11$ is an Egyptian number. The numbers which are *not* Egyptian are 2, 3, 5, 6, 7, 8, 12, 13, 14, 15, 19, 21, and 23 (Sloane's A028229; Konhauser *et al.* 1996, p. 147).

If n is the sum of denominators of a unit fraction representation composed of *distinct* denominators which are not all 1s, then it is called a strictly Egyptian number. For example, by virtue of

$$1 = \frac{1}{2} + \frac{1}{2},$$

$2 + 2 = 4$ is Egyptian, but it is *not* strictly Egyptian. Graham (1963) proved that every number ≥ 78 is strictly Egyptian. Numbers which are strictly Egyptian are 11, 24, 30, 31, 32, 37, 38, 43, ... (Sloane's A052428), and those which are not are 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, ... (Sloane's A051882).

Ehrhart Polynomial

Let Δ denote an integral convex POLYTOPE of DIMENSION n in a lattice M, and let $l_\Delta(k)$ denote the number of LATTICE POINTS in Δ dilated by a factor of the integer k,

$$l_\Delta(k) = \#(k\Delta \cap M) \qquad (1)$$

for $k \in \mathbb{Z}^+$. Then l_Δ is a polynomial function in k of degree n with rational coefficients

$$l_\Delta(k) = a_n k^n + a_{n-1} k^{n-1} + \ldots + a_0 \qquad (2)$$

called the Ehrhart polynomial (Ehrhart 1967, Pommersheim 1993). Specific coefficients have important geometric interpretations.

1. a_n is the CONTENT of Δ.
2. a_{n-1} is half the sum of the CONTENTS of the $(n-1)$-D faces of Δ.
3. $a_0 = 1$.

Let $S_2(\Delta)$ denote the sum of the lattice lengths of the edges of Δ, then the case $n = 2$ corresponds to PICK'S THEOREM,

$$l_\Delta(k) = \mathrm{Vol}(\Delta)k^2 + \tfrac{1}{2} S_2(\Delta) + 1. \qquad (3)$$

Let $S_3(\Delta)$ denote the sum of the lattice volumes of the 2-D faces of Δ, then the case $n = 3$ gives

$$l_\Delta(k) = \mathrm{Vol}(\Delta)k^3 + \tfrac{1}{2} S_3(\Delta)k^2 + a_1 k + 1, \qquad (4)$$

where a rather complicated expression is given by Pommersheim (1993), since a_1 can unfortunately *not* be interpreted in terms of the edges of Δ. The Ehrhart polynomial of the tetrahedron with vertices at (0, 0, 0), $(a, 0, 0)$, $(0, b, 0)$, $(0, 0, c)$ is

$$\begin{aligned} l_\Delta(k) &= \tfrac{1}{6} abck^3 + \tfrac{1}{4}(ab + ac + bc + d)k^2 \\ &+ \left[\frac{1}{12}\left(\frac{ac}{b} + \frac{bc}{a} + \frac{ab}{c} + \frac{d^2}{abc}\right) + \tfrac{1}{4}(a + b + c + A + B + C)\right. \\ &- As\left(\frac{bc}{d}, \frac{aA}{d}\right) - Bs\left(\frac{ac}{d}, \frac{bB}{d}\right) \\ &\left. - Cs\left(\frac{ab}{d}, \frac{cC}{d}\right)\right] k + 1, \end{aligned} \qquad (5)$$

where $s(x, y)$ is a DEDEKIND SUM, $A = \mathrm{GCD}(b, c)$, $B = \mathrm{GCD}(a, c)$, $C = \mathrm{GCD}(a, b)$ (here, GCD is the GREATEST COMMON DIVISOR), and $d = ABC$ (Pommersheim 1993).

Ei

EXPONENTIAL INTEGRAL, *En*-FUNCTION

Eigenform

Given a DIFFERENTIAL OPERATOR D on the space of DIFFERENTIAL FORMS, an eigenform is a form α such that

$$D\alpha = \lambda\alpha$$

for some constant λ. For example, on the TORUS, the DIRAC OPERATOR $D = -i(d + d^*)$ acts on the form

$$\beta = 3e^{i(3x+4y)} + 5e^{i(3x+4y)}\, dx - 4e^{i(3x+4y)}\, dx \wedge dy,$$

giving

$$D\beta = 15e^{i(3x+4y)} + 25e^{i(3x+4y)}\, dx - 20e^{i(3x+4y)}\, dx \wedge dy,$$

i.e., $D\beta = 5\beta$.

See also DIRAC OPERATOR, LAPLACIAN, SPECTRUM (OPERATOR)

Eigenfunction

If $\tilde{L}$ is a linear OPERATOR on a FUNCTION SPACE, then f is an eigenfunction for $\tilde{L}$ and λ is the associated EIGENVALUE whenever $\tilde{L}f = \lambda f$.

See also EIGENVALUE, EIGENVECTOR, FUNCTIONAL

Eigenspace

If A is an $n \times n$ matrix, and λ is an EIGENVALUE of A, then the union of the ZERO VECTOR and the set of all EIGENVECTORS corresponding to λ is a SUBSPACE of $\mathbb{R}^n$ known as the EIGENSPACE of λ.

Eigenvalue

Let A be a linear transformation represented by a MATRIX A. If there is a VECTOR $\mathbf{X} \in \mathbb{R}^n \neq 0$ such that

$$\mathsf{A}\mathbf{X} = \lambda \mathbf{X} \tag{1}$$

for some SCALAR λ, then λ is called the eigenvalue of A with corresponding (right) EIGENVECTOR $\mathbf{X}$. Eigenvalues are also known as characteristic roots, proper values, or latent roots (Marcus and Minc 1988, p. 144).

Letting A be a $k \times k$ MATRIX,

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} \end{bmatrix} \tag{2}$$

with eigenvalue λ, then the corresponding EIGENVECTORS satisfy

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix} = \lambda \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix}, \tag{3}$$

which is equivalent to the homogeneous system

$$\begin{bmatrix} a_{11}-\lambda & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22}-\lambda & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk}-\lambda \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}. \tag{4}$$

Equation (4) can be written compactly as

$$(\mathsf{A} - \lambda \mathsf{I})\mathbf{X} = 0, \tag{5}$$

where I is the IDENTITY MATRIX. This MATRIX EQUATION can then be solved for λ.

Eigenvalues are given by the solutions of the CHARACTERISTIC EQUATION of a given matrix. For example, for a 2×2 matrix, the eigenvalues are

$$\lambda_{\pm} = \tfrac{1}{2}\left[(a_{11}+a_{22}) \pm \sqrt{4a_{12}a_{21} + (a_{11}-a_{22})^2}\right], \tag{6}$$

which arises as the solutions of the CHARACTERISTIC EQUATION

$$x^2 - x(a_{11}+a_{22}) + (a_{11}a_{22} - a_{12}a_{21}) = 0, \tag{7}$$

which can be written

$$x^2 - x\mathrm{Tr}(\mathsf{A}) + \det(\mathsf{A}) = 0, \tag{8}$$

where $\mathrm{Tr}(\mathsf{A})$ is the TRACE of A and $\det(\mathsf{A})$ is its DETERMINANT. The CHARACTERISTIC EQUATION for the 3×3 case is

$$x^3 - \mathrm{Tr}(\mathsf{A})x^2 - \tfrac{1}{2}(a_{ij}a_{ji} - a_{ii}a_{jj})(1-\delta_{ij})x - \det(\mathsf{A}) = 0, \tag{9}$$

where δ_{ij} is the KRONECKER DELTA and EINSTEIN SUMMATION has been used. The corresponding analytic eigenvalue expressions for 4×4 and larger matrices are very complicated.

As shown in CRAMER'S RULE, a system of linear equations has nontrivial solutions only if the DETERMINANT vanishes, so we obtain the CHARACTERISTIC EQUATION

$$|\mathsf{A} - \lambda \mathsf{I}| = 0. \tag{10}$$

If all k λs are different, then plugging these back in gives $k-1$ independent equations for the k components of each corresponding EIGENVECTOR. The EIGENVECTORS will then be orthogonal and the system is said to be nondegenerate. If the eigenvalues are n-fold DEGENERATE, then the system is said to be degenerate and the EIGENVECTORS are not linearly independent. In such cases, the additional constraint that the EIGENVECTORS be ORTHOGONAL,

$$\mathbf{X}_i \cdot \mathbf{X}_j = |\mathbf{X}_i||\mathbf{X}_j|\delta_{ij}, \tag{11}$$

where δ_{ij} is the KRONECKER DELTA, can be applied to yield n additional constraints, thus allowing solution for the EIGENVECTORS.

Assume A has nondegenerate eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_k$ and corresponding linearly independent EIGENVECTORS $\mathbf{X}_1, \mathbf{X}_2, \ldots, \mathbf{X}_k$ which can be denoted

$$\begin{bmatrix} x_{11} \\ x_{12} \\ \vdots \\ x_{1k} \end{bmatrix}, \begin{bmatrix} x_{21} \\ x_{22} \\ \vdots \\ x_{2k} \end{bmatrix}, \cdots \begin{bmatrix} x_{k1} \\ x_{k2} \\ \vdots \\ x_{kk} \end{bmatrix}. \tag{12}$$

Define the matrices composed of eigenvectors

$$\mathsf{P} \equiv [\mathbf{X}_1 \quad \mathbf{X}_2 \quad \cdots \quad \mathbf{X}_k] = \begin{bmatrix} x_{11} & x_{21} & \cdots & x_{k1} \\ x_{12} & x_{22} & \cdots & x_{k2} \\ \vdots & \vdots & \ddots & \vdots \\ x_{1k} & x_{2k} & \cdots & x_{kk} \end{bmatrix} \tag{13}$$

and eigenvalues

$$\mathsf{D} \equiv \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k \end{bmatrix}, \tag{14}$$

where D is a DIAGONAL MATRIX. Then

$$\mathsf{AP} = \mathsf{A}[\mathbf{X}_1 \quad \mathbf{X}_2 \ \cdots \ \mathbf{X}_k]$$

$$= [\mathsf{A}\mathbf{X}_1 \quad \mathsf{A}\mathbf{X}_2 \ \cdots \ \mathsf{A}\mathbf{X}_k]$$

$$= [\lambda_1\mathbf{X}_1 \quad \lambda_2\mathbf{X}_2 \ \cdots \ \lambda_k\mathbf{X}_k]$$

$$= \begin{bmatrix} \lambda_1 x_{11} & \lambda_2 x_{21} & \cdots & \lambda_k x_{k1} \\ \lambda_1 x_{12} & \lambda_2 x_{22} & \cdots & \lambda_k x_{k2} \\ \vdots & \vdots & \ddots & \vdots \\ \lambda_1 x_{1k} & \lambda_2 x_{2k} & \cdots & \lambda_k x_{kk} \end{bmatrix}$$

$$= \begin{bmatrix} x_{11} & x_{21} & \cdots & x_{k1} \\ x_{12} & x_{22} & \cdots & x_{k2} \\ \vdots & \vdots & \ddots & \vdots \\ x_{1k} & x_{2k} & \cdots & x_{kk} \end{bmatrix} \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k \end{bmatrix}$$

$$= \mathsf{PD}, \tag{15}$$

so

$$\mathsf{A} = \mathsf{PDP}^{-1}. \tag{16}$$

Furthermore,

$$\mathsf{A}^2 = (\mathsf{PDP}^{-1})(\mathsf{PDP}^{-1}) = \mathsf{PD}(\mathsf{P}^{-1}\mathsf{P})\mathsf{DP}^{-1}$$

$$= \mathsf{PD}^2\mathsf{P}^{-1}. \tag{17}$$

By induction, it follows that for $n > 0$,

$$\mathsf{A}^n = \mathsf{PD}^n\mathsf{P}^{-1}. \tag{18}$$

The inverse of A is

$$\mathsf{A}^{-1} = (\mathsf{PDP}^{-1})^{-1} = \mathsf{PD}^{-1}\mathsf{P}^{-1}, \tag{19}$$

where the inverse of the DIAGONAL MATRIX D is trivially given by

$$\mathsf{D}^{-1} = \begin{bmatrix} \lambda_1^{-1} & 0 & \cdots & 0 \\ 0 & \lambda_2^{-1} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k^{-1} \end{bmatrix}. \tag{20}$$

Equation (18) therefore holds for both POSITIVE and NEGATIVE n.

A further remarkable result involving the matrices P and D follows from the definition

$$e^{\mathsf{A}} \equiv \sum_{n=0}^{\infty} \frac{\mathsf{A}^n}{n!} = \sum_{n=0}^{\infty} \frac{\mathsf{PD}^n\mathsf{P}^{-1}}{n!}$$

$$= \mathsf{P}\left(\frac{\sum_{n=0}^{\infty} \mathsf{D}^n}{n!}\right)\mathsf{P}^{-1} = \mathsf{P}e^{\mathsf{D}}\mathsf{P}^{-1}. \tag{21}$$

Since D is a DIAGONAL MATRIX,

$$e^{\mathsf{D}} = \sum_{n=0}^{\infty} \frac{\mathsf{D}^n}{n!} = \sum_{n=0}^{\infty} \frac{1}{n!} \begin{bmatrix} \lambda_1^n & 0 & \cdots & 0 \\ 0 & \lambda_2^n & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k^n \end{bmatrix}$$

$$= \begin{bmatrix} \sum_{n=0}^{\infty} \frac{\lambda_1^n}{n!} & 0 & \cdots & 0 \\ 0 & \sum_{n=0}^{\infty} \frac{\lambda_2^n}{n!} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \sum_{n=0}^{\infty} \frac{\lambda_k^n}{n!} \end{bmatrix}$$

$$= \begin{bmatrix} e^{\lambda_1} & 0 & \cdots & 0 \\ 0 & e^{\lambda_2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & e^{\lambda_k} \end{bmatrix}, \tag{22}$$

e^{D} can be found using

$$\mathsf{D}^n = \begin{bmatrix} \lambda_1^n & 0 & \cdots & 0 \\ 0 & \lambda_2^n & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k^n \end{bmatrix}. \tag{23}$$

Assume we know the eigenvalue for

$$\mathsf{A}\mathbf{X} = \lambda\mathbf{X}. \tag{24}$$

Adding a constant times the IDENTITY MATRIX to A,

$$(\mathsf{A} + c\mathsf{I})\mathbf{X} = (\lambda + c)\mathbf{X} \equiv \lambda'\pi\mathbf{X}, \tag{25}$$

so the new eigenvalues equal the old plus c. Multiplying A by a constant c

$$(c\mathsf{A})\mathbf{X} = c(\lambda\mathbf{X}) \equiv \lambda'\mathbf{X}, \tag{26}$$

so the new eigenvalues are the old multiplied by c.

Now consider a SIMILARITY TRANSFORMATION of A. Let $|\mathsf{A}|$ be the DETERMINANT of A, then

$$|\mathsf{Z}^{-1}\mathsf{AZ} - \lambda\mathsf{I}| = |\mathsf{Z}^{-1}(\mathsf{A} - \lambda\mathsf{I})\mathsf{Z}|$$

$$= |\mathsf{Z}||\mathsf{A} - \lambda\mathsf{I}||\mathsf{Z}^{-1}| = |\mathsf{A} - \lambda\mathsf{I}|, \tag{27}$$

so the eigenvalues are the same as for A.

Eigenvector

A right eigenvector satisfies

$$\mathsf{A}\mathbf{X} = \lambda \mathbf{X}, \tag{1}$$

where $\mathbf{X}$ is a column VECTOR. The right EIGENVALUES therefore satisfy

$$|\mathsf{A} - \lambda \mathsf{I}| = 0. \tag{2}$$

A left eigenvector satisfies

$$\mathsf{X}\mathsf{A} = \lambda \mathbf{X}, \tag{3}$$

where $\mathbf{X}$ is a row VECTOR, so

$$(\mathbf{X}\mathsf{A})^{\mathrm{T}} = \lambda_L \mathbf{X}^{\mathrm{T}}, \tag{4}$$

$$\mathsf{A}^{\mathrm{T}}\mathbf{X}^{\mathrm{T}} = \lambda_L \mathbf{X}_T, \tag{5}$$

where $\mathbf{X}^{\mathrm{T}}$ is the transpose of $\mathbf{X}$.

The left EIGENVALUES satisfy

$$|\mathsf{A}^{\mathrm{T}} - \lambda_L \mathsf{I}| = |\mathsf{A}^{\mathrm{T}} - \lambda_L \mathsf{I}^{\mathrm{T}}| = |(\mathsf{A} - \lambda_L \mathsf{I})^{\mathrm{T}}| = |(\mathsf{A} - \lambda_L \mathsf{I})|, \tag{6}$$

(since $|\mathsf{A}| = |\mathsf{A}^{\mathrm{T}}|$) where $|\mathsf{A}|$ is the DETERMINANT of A. But this is the same equation satisfied by the right EIGENVALUES, so the left and right EIGENVALUES are the same. Let $\mathbf{X}_R$ be a MATRIX formed by the columns of the right eigenvectors and $\mathbf{X}_L$ be a MATRIX formed by the rows of the left eigenvectors. Let

$$\mathsf{D} \equiv \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_n \end{bmatrix}. \tag{7}$$

Then

$$\mathsf{A}\mathbf{X}_{\mathrm{R}} = \mathbf{X}_{\mathrm{R}}\mathsf{D} \quad \mathbf{X}_L\mathsf{A} = \mathsf{D}\mathbf{X}_L \tag{8}$$

$$\mathrm{X}_L\mathsf{A}\mathbf{X}_R = \mathbf{X}_L\mathbf{X}_R\mathsf{D} \quad \mathbf{X}_L\mathsf{A}\mathbf{X}_R = \mathsf{D}\mathbf{X}_L\mathbf{X}_R, \tag{9}$$

so

$$\mathbf{X}_L\mathbf{X}_R\mathsf{D} = \mathsf{D}\mathbf{X}_L\mathbf{X}_R. \tag{10}$$

But this equation is OF THE FORM $\mathsf{CD} = \mathsf{DC}$ where D is a DIAGONAL MATRIX, so it must be true that $\mathsf{C} \equiv \mathbf{X}_L\mathbf{X}_R$ is also diagonal. In particular, if A is a SYMMETRIC MATRIX, then the left and right eigenvectors are transposes of each other. If A is a SELF-ADJOINT MATRIX, then the left and right eigenvectors are conjugate HERMITIAN MATRICES.

Eigenvectors are sometimes known as characteristic vectors, proper vectors, or latent vectors (Marcus and Minc 1988, p. 144).

Given a 3×3 MATRIX A with eigenvectors $\mathbf{x}_1$, $\mathbf{x}_2$, and $\mathbf{x}_3$ and corresponding EIGENVALUES λ_1, λ_2, and λ_3, then an arbitrary VECTOR $\mathbf{y}$ can be written

$$y = b_1\mathbf{x}_1 + b_2\mathbf{x}_2 + b_3\mathbf{x}_3. \tag{11}$$

Applying the MATRIX A,

$$\begin{aligned} \mathsf{A}\mathbf{y} &= b_1 A\mathbf{x}_1 + b_2 A\mathbf{x}_2 + b_3 A\mathbf{x}_3 \\ &= \lambda_1\left(b_1\mathbf{x}_1 + \frac{\lambda_2}{\lambda_1}\, b_2\mathbf{x}_2 + \frac{\lambda_3}{\lambda_1}\, b_3\mathbf{x}_3\right), \end{aligned} \tag{12}$$

so

$$\mathsf{A}^n\mathbf{y} = \lambda_1^n\left[b_1\mathbf{x}_1 + \left(\frac{\lambda_2}{\lambda_1}\right)^n b_2\mathbf{x}_2 + \left(\frac{\lambda_3}{\lambda_1}\right)^n b_3\mathbf{x}_3\right]. \tag{13}$$

If $\lambda_1 > \lambda_2,\ \lambda_3$, it therefore follows that

$$\lim_{n\to\infty} \mathsf{A}^n\mathbf{y} = \lambda_1^n b_1\mathbf{x}_I, \tag{14}$$

so repeated application of the matrix to an arbitrary vector results in a vector proportional to the EIGENVECTOR having the largest EIGENVALUE.

Eight-Point Circle Theorem

Let *ABCD* be a QUADRILATERAL with PERPENDICULAR DIAGONALS. The MIDPOINTS of the sides (a, b, c, and d) determine a PARALLELOGRAM (the VARIGNON PARALLELOGRAM) with sides PARALLEL to the DIAGONALS. The eight-point circle passes through the four MIDPOINTS and the four feet of the PERPENDICULARS from the opposite sides a', b', c', and d'.

Eikonal Equation

$$\sum_{i=1}^{n} \left(\frac{\partial u}{\partial x_i}\right)^2 = 1.$$

Eilenberg-Mac Lane Space

For any ABELIAN GROUP G and any NATURAL NUMBER n, there is a unique SPACE (up to HOMOTOPY type) such that all HOMOTOPY GROUPS except for the nth are trivial (including the 0th HOMOTOPY GROUPS, meaning the SPACE is path-connected), and the nth HOMOTOPY GROUP is ISOMORPHIC to the GROUP G. In the case where $n = 1$, the GROUP G can be non-ABELIAN as well.

Eilenberg-Mac Lane spaces have many important applications. One of them is that every TOPOLOGICAL SPACE has the HOMOTOPY type of an iterated FIBRATION of Eilenberg-Mac Lane spaces (called a POSTNIKOV SYSTEM). In addition, there is a spectral sequence relating the COHOMOLOGY of Eilenberg-Mac Lane spaces to the HOMOTOPY GROUPS of SPHERES.

Eilenberg-Mac Lane-Steenrod-Milnor Axioms

EILENBERG-STEENROD AXIOMS

Eilenberg-Steenrod Axioms

A family of FUNCTORS $H_n(\cdot)$ from the CATEGORY of pairs of TOPOLOGICAL SPACES and continuous maps, to the CATEGORY of ABELIAN GROUPS and group homomorphisms satisfies the Eilenberg-Steenrod axioms if the following conditions hold.

1. LONG EXACT SEQUENCE OF A PAIR AXIOM. For every pair (X, A), there is a natural long exact sequence

$$\ldots \to H_n(A) \to H_n(X) \to H_n(X, A) \to H_{n-1}(A) \to \ldots, \quad (1)$$

where the MAP $H_n(A) \to H_n(X)$ is induced by the INCLUSION MAP $A \to X$ and $H_n(X) \to H_n(X, A)$ is induced by the INCLUSION MAP $(X, \phi) \to (X, A)$. The MAP $H_n(X, A) \to H_{n-1}(A)$ is called the BOUNDARY MAP.

2. HOMOTOPY AXIOM. If $f : (X, A) \to (Y, B)$ is homotopic to $g : (X, A) \to (Y, B)$, then their INDUCED MAPS $f_* : H_n(X, A) \to H_n(Y, B)$ and $g_* : H_n(X, A) \to H_n(Y, B)$ are the same.

3. EXCISION AXIOM. If X is a SPACE with SUBSPACES A and U such that the CLOSURE of A is contained in the interior of U, then the INCLUSION MAP $(X\ U, A\ U) \to (X, A)$ induces an isomorphism $H_n(X\ U, A\ U) \to H_n(X, A)$.

4. DIMENSION AXIOM. Let X be a single point space. $H_n(X) = 0$ unless $n = 0$, in which case $H_0(X) = G$ where G are some GROUPS. The H_0 are called the COEFFICIENTS of the HOMOLOGY theory $H()$.

These are the axioms for a generalized homology theory. For a cohomology theory, instead of requiring that $H(\cdot)$ be a FUNCTOR, it is required to be a co-functor (meaning the INDUCED MAP points in the opposite direction). With that modification, the axioms are essentially the same (except that all the induced maps point backwards).

See also ALEKSANDROV-CECH COHOMOLOGY

Ein Function

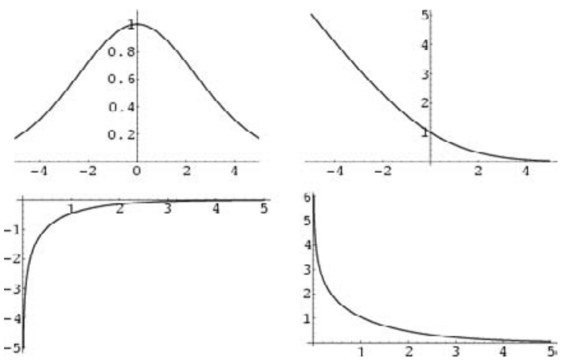
$$\mathrm{Ein}(z) \equiv \int_0^z \frac{(1 - e^{-t})\,dt}{t} = E_1(z) + \ln z + \gamma,$$

where γ is the EULER-MASCHERONI CONSTANT and E^1 is the *En*-FUNCTION with $n = 1$.

See also *En*-FUNCTION

Einstein Field Equations

The 16 coupled hyperbolic-elliptic nonlinear PARTIAL DIFFERENTIAL EQUATIONS that describe the gravitational effects produced by a given mass in general relativity. The equations state that



$$G_{\mu\nu} = 8\pi T_{\mu\nu},$$

where $T_{\mu\nu}$ is the stress-energy tensor, and

$$G_{\mu\nu} = R_{\mu\nu} - \tfrac{1}{2} g_{\mu\nu} R$$

is the EINSTEIN TENSOR, with $R_{\mu\nu}$ the RICCI TENSOR and R the SCALAR CURVATURE.

Einstein Functions

The functions

$$E_1(x) = \frac{x^2 e^x}{(e^x - 1)^2} \quad (1)$$

$$E_2(x) = \frac{x}{e^x - 1} \quad (2)$$

$$E_3(x) = \ln(1 - e^{-x}) \quad (3)$$

$$E_4(x) = \frac{x}{e^x - 1} - \ln(1 - e^{-x}). \quad (4)$$

$E_1(x)$ has an inflection point at

$$E_1''(x) = \tfrac{1}{8}\,\mathrm{csch}^4(\tfrac{1}{2}x)[(x^2 + 2)\cosh x + 2(x^2 - 2x\sinh x - 1)] = 0 \quad (5)$$

which can be solved numerically to give $x \approx 2.34693$. $E_1(x)$ has an inflection point at

$$E_2''(x) = \frac{e^x[x + 2 + e^x(x - 2)]}{(e^x - 1)^3} = 0, \quad (6)$$

which can be solved numerically to give $x \approx 17.5221$.

Einstein Summation

The convention that repeated indices are implicitly summed over. This can greatly simplify and shorten equations involving TENSORS. For example, using Einstein summation,

$$a_i a_i \equiv \sum_i a_i a_i$$

and

$$a_{ik} a_{ij} = \sum_i a_{ik} a_{ij}.$$

The convention was introduced by Einstein (1916), who later jested to a friend,"I have made a great discovery in mathematics; I have suppressed the summation sign every time that the summation must be made over an index which occurs twice..." (Kollros 1956; Pais 1982, p. 216).

Einstein Tensor

$$G_{ab} = R_{ab} - \tfrac{1}{2} R g_{ab},$$

where R_{ab} is the RICCI TENSOR, R is the SCALAR CURVATURE, and g_{ab} is the METRIC TENSOR. (Wald 1984, pp. 40–1). It satisfies

$$G^{\mu\nu}{}_{;\nu} = 0$$

(Misner *et al.* 1973, p. 222).

Eisenstein Integer

The numbers $a + b\omega$, where

$$\omega \equiv \tfrac{1}{2}(-1 + i\sqrt{3})$$

is one of the ROOTS of $z^3 = 1$, the others being 1 and

$$\omega^2 \equiv \tfrac{1}{2}(-1 - i\sqrt{3}).$$

Eisenstein integers are members of the IMAGINARY QUADRATIC FIELD $\mathbb{Q}(\sqrt{-3})$, and the COMPLEX NUMBERS $\mathbb{Z}[\omega]$. Every Eisenstein integer has a unique factorization. Specifically, any NONZERO Eisenstein integer is uniquely the product of POWERS of -1, ω, and the "positive" EISENSTEIN PRIMES (Conway and Guy 1996). Every Eisenstein integer is within a distance $|n|/\sqrt{3}$ of some multiple of a given Eisenstein integer n.

Dörrie (1965) uses the alternative notation

$$J \equiv \tfrac{1}{2}(1 + i\sqrt{3}) \quad (1)$$

$$O \equiv \tfrac{1}{2}(1 - i\sqrt{3}). \quad (2)$$

for $-\omega^2$ and $-\omega$, and calls numbers OF THE FORM $aJ + bO$ G-NUMBERS. O and J satisfy

$$J + O = 1 \quad (3)$$

$$JO = 1 \quad (4)$$

$$J^2 + O = 0 \quad (5)$$

$$O^2 + J = 0 \quad (6)$$

$$J^3 = -1 \quad (7)$$

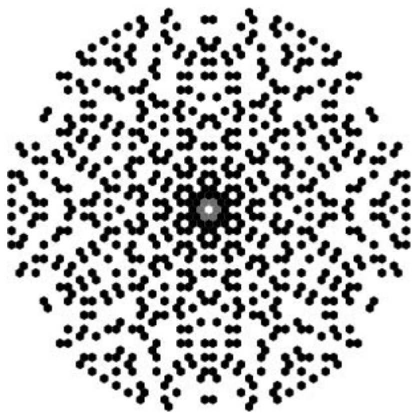
$$O^3 = -1. \quad (8)$$

The sum, difference, and products of G numbers are also G numbers. The norm of a G number is

$$N(aJ + bO) = a^2 + b^2 - ab. \quad (9)$$

The analog of FERMAT'S THEOREM for Eisenstein integers is that a PRIME NUMBER p can be written in the form

$$a^2 - ab + b^2 = (a + b\omega)(a + b\omega^2)$$



IFF $3 \nmid p + 1$. These are precisely the PRIMES OF THE FORM $3m^2 + n^2$ (Conway and Guy 1996).

Eisenstein Prime

Let ω be the CUBE ROOT of unity $(-1+i\sqrt{3})/2$. Then the Eisenstein primes are

1. Ordinary PRIMES CONGRUENT to 2 (mod 3),
2. $1-\omega$ is prime in $\mathbb{Z}[\omega]$,
3. Any ordinary PRIME CONGRUENT to 1 (mod 3) factors as $\alpha\alpha^*$, where each of α and α^* are primes in $\mathbb{Z}[\omega]$ and α and α^* are not "associates" of each other (where associates are equivalent modulo multiplication by an EISENSTEIN UNIT).

Eisenstein Series

$$G_r(\tau)=\sum_{m,n}{}' \frac{1}{(m+n\tau)^{2r}}, \tag{1}$$

where the sum Σ' excludes $m=n=0$, $\mathfrak{I}[\tau]>0$, and r is an INTEGER with $r>2$. The Eisenstein series satisfies the remarkable property

$$G_r\left(\frac{a\tau+b}{c\tau+d}\right)=(ct+d)^{2r}E_r(\tau). \tag{2}$$

Furthermore, each Eisenstein series is expressible as a polynomial of the INVARIANTS g_2 and g_3 of the WEIERSTRASS ELLIPTIC FUNCTION with positive rational coefficients (Apostol 1997).

The Eisenstein series of EVEN order satisfy

$$G_{2k}(\tau)=2\zeta(2k)+\frac{2(2\pi i)^{2k}}{(2k-1)!}\sum_{n=1}^{\infty}\sigma_{2k-1}(n)e^{2\pi i n\tau}, \tag{3}$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION and $\sigma_k(n)$ is the DIVISOR FUNCTION (Apostol 1997, pp. 24 and 69). Writing the NOME q as

$$q=e^{\pi\tau i}=e^{-\pi K'(k)/K(k)} \tag{4}$$

where $K(k)$ is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND, $K'(k)\equiv K(\sqrt{1-k^2})$, k is the MODULUS, and defining

$$E_{2k}(q)\equiv\frac{G_{2k}(\tau)}{2\zeta(2k)}, \tag{5}$$

we have

$$E_{2n}(q)=1+c_{2n}\sum_{k=1}^{\infty}\frac{k^{n-1}q^{2k}}{1-q^{2k}} \tag{6}$$

$$=1+c_{2n}\sum_{k=1}^{\infty}\sigma_{2n-1}(k)q^{2k}. \tag{7}$$

where

$$c_{2n}=\frac{(2\pi i)^{2k}}{(2k-1)!\zeta(2k)}=(-1)^k\frac{(2\pi)^{2k}}{\Gamma(2k)\zeta(2k)}. \tag{8}$$

$$=-\frac{4n}{B_{2n}}, \tag{9}$$

where B_n is a BERNOULLI NUMBER. For $n=1, 2, \ldots$, the first few values of c_{2n} are -24, 240, -504, 480, -264, 65520/691, ... (Sloane's A006863 and A001067).

The first few values of $E_{2n}(q)$ are therefore

$$E_2(q)=1-24\sum_{k=1}^{\infty}\sigma_1(k)q^{2k} \tag{10}$$

$$E_4(q)=1+240\sum_{k=1}^{\infty}\sigma_3(k)q^{2k} \tag{11}$$

$$E_6(q)=1-504\sum_{k=1}^{\infty}\sigma_5(k)q^{2k} \tag{12}$$

$$E_8(q)=1+480\sum_{k=1}^{\infty}\sigma_7(k)q^{2k} \tag{13}$$

$$E_{10}(q)=1-264\sum_{k=1}^{\infty}\sigma_9(k)q^{2k} \tag{14}$$

$$E_{12}(q)=1+\frac{65520}{691}\sum_{k=1}^{\infty}\sigma_{11}(k)q^{2k} \tag{15}$$

$$E_{14}(q)=1-24\sum_{k=1}^{\infty}\sigma_{13}(k)q^{2k}, \tag{16}$$

(Apostol 1997, p. 139). Ramanujan used the notations $P(z)=E_2(\sqrt{z})$, $Q(z)=E_4(\sqrt{z})$, and $R(z)=E_6(\sqrt{z})$, and these functions satisfy the system of differential

equations

$$\vartheta P = \tfrac{1}{12}(P^2 - Q) \quad (17)$$

$$\vartheta Q = \tfrac{1}{3}(PQ - R) \quad (18)$$

$$\vartheta R = \tfrac{1}{2}(PR - Q^2) \quad (19)$$

(Nesterenko 1999), where $\vartheta = z d/dz$ is the DIFFERENTIAL OPERATOR.

$E_{2n}(q)$ can also be expressed in terms of complete ELLIPTIC INTEGRALS OF THE FIRST KIND $K(k)$ as

$$E_4(q) = \left(\frac{2K(k)}{\pi}\right)^4 (1 - k^2 k'^2) \quad (20)$$

$$E_6(q) = \left(\frac{2K(k)}{\pi}\right)^6 (1 - 2k^2)(1 + \tfrac{1}{2} k^2 k'^2) \quad (21)$$

(Ramanujan 1913–914), where k is the MODULUS.

The following table gives the first few Eisenstein series $E_n(q)$ for even n.

n	Sloane	lattice	$E_n(q)$
2	A006352		$1-24q^2-72q^4-96q^6-168q^8-\cdots$
4	A004009	E_8	$1+240q^2+2160q^4+6720q^6+\cdots$
6	A013973		$1-504q^2-16632q^4-122976q^6-\cdots$
8	A008410	$E_8 \oplus E_8$	$1+480q^2+61920q^4+1050240q^6+\cdots$
10	A013974		$y = r' \sin\theta'$.

Ramanujan (1913–914) used the notation $L(q)$ to refer to the closely related function

$$L(q) = 1 + 24 \sum_{k=1}^{\infty} \sigma_1^{(0)}(n)(-1)^k q^k \quad (22)$$

$$= 1 - 24 \sum_{k=1}^{\infty} \frac{(2k-1)q^{2k-1}}{1+q^{2k-1}}$$

$$= \left(\frac{2K(k)}{\pi}\right)^2 (1 - 2k^2) \quad (23)$$

$$= 1 - 24q + 24q^2 - 96q^3 + \cdots \quad (24)$$

(Sloane's A004011), where

$$\sigma_1^{(0)}(n) \equiv \sum_{d|nd \text{ odd}} d \quad (25)$$

is the ODD DIVISOR FUNCTION. Ramanujan used the notation $M(q)$ and $N(q)$ to refer to $E_4(q)$ and $E_6(q)$, respectively.

Elastica

The elastica formed by bent rods and considered in physics can be generalized to curves in a RIEMANNIAN MANIFOLD which are a CRITICAL POINT for

$$F^{\lambda}(\gamma)=\int_{\gamma}(\kappa^2+\lambda),$$

where κ is the GEODESIC CURVATURE of γ, λ is a REAL NUMBER, and γ is closed or satisfies some specified boundary condition. The curvature of an elastica must satisfy

$$0=2\kappa''(s)+\kappa^3(s)+2\kappa(s)G(s)-\lambda\kappa(s),$$

where κ is the signed curvature of γ, $G(s)$ is the GAUSSIAN CURVATURE of the oriented Riemannian surface M along γ, κ'' is the second derivative of κ with respect to s, and λ is a constant.

Element

If x is a member of a set A, then x is said to be an element of A, written $x\in A$. If x is not an element of A, this is written $x\notin A$. The term element also refers to a particular member of a GROUP, or entry a_{ij} in a MATRIX A or unevaluated DETERMINANT $\det(\mathsf{A})$.

See also SET THEORY

Elementary Cellular Automaton

The simplest class of 1-D cellular automata. They have two possible values for each cell, and rules that depend only on nearest neighbor values. They can be indexed with an 8-bit binary number, as shown by Stephen Wolfram (1983). Wolfram further restricted the number from $2^8=256$ to 32 by requiring certain symmetry conditions. The illustrations above show automata numbers 30 and 90 propagated for 256 generations. Rule 30 is chaotic, with central column given by 1, 1, 0, 1, 1, 1, 0, 0, 1, 1, 0, 0, 0, 1, ... (Sloane's A051023).

Elementary Function

A function built up of a finite combination of constant functions, field operations (ADDITION, MULTIPLICATION, DIVISION, and ROOT EXTRACTIONS–the ELEMENTARY OPERATIONS)–and algebraic, exponential, and logarithmic functions and their inverses under repeated compositions (Shanks 1993, p. 145; Chow 1999). Among the simplest elementary functions are the LOGARITHM, EXPONENTIAL FUNCTION (including the HYPERBOLIC FUNCTIONS), POWER function, and TRIGONOMETRIC FUNCTIONS.

Following Liouville (1837, 1838, 1839), Watson (1966, p. 111) defines the elementary TRANSCENDENTAL FUNCTIONS as

$$l_1(z) \equiv l(z) \equiv \ln(z)$$
$$e_1(z) \equiv e(z) \equiv e^z$$
$$\zeta_1 f(z) \equiv \zeta f(z) \equiv \int f(z)\,dz,$$

and lets $l_2 \equiv l(l(z))$, etc.

Not all functions are elementary. For example, the NORMAL DISTRIBUTION FUNCTION

$$\Phi(x) \equiv \frac{1}{\sqrt{2\pi}} \int_0^x e^{-t^2/2}\,dt$$

is a notorious example of a nonelementary function. The ELLIPTIC INTEGRAL

$$\int \sqrt{1-x^4}\,dx$$

is another.

Elementary Symmetric Function

The elementary symmetric functions $1-24\Sigma_{k=1}^{\infty}\frac{(2k-1)q^{2_1-1}}{1+q^{2k-1}}$ on $p(n)$ variables $\left(\frac{2K(k)}{\pi}\right)^2(1-2k^2)$ are defined by

$$1-24q+24q^2-96q^3+\ldots=\sigma_1^{(0)}(n)\equiv\sum_{d|nd\ \text{odd}} d \quad (1)$$

$$M(q)=N(q) \quad (2)$$

$$E_4(q)=E_6(q) \quad (3)$$

$$G_2(\tau)=O_{s+2,\ 2}(R)^+ \quad (4)$$

$$1/\pi$$

$$\pm 1=\pm\omega \quad (5)$$

Alternatively, $\pm\omega^2$ can be defined as the coefficient of ω in the GENERATING FUNCTION

$$\tfrac{1}{2}(-1+i\sqrt{3}) \quad (6)$$

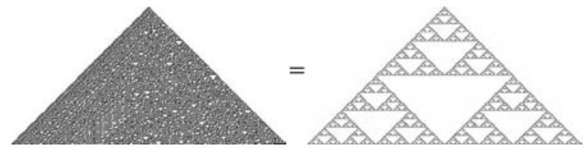
For example, on four variables ω^2, ..., $\frac{1}{2}(-1-i\sqrt{3})$, the elementary symmetric functions are

$$1-24q+24q^2-96q^3+\ldots=F^{\lambda}(\gamma)=\int_{\gamma}(\kappa^2+\lambda), \quad (7)$$

$$M(q)=\kappa \quad (8)$$

$$E_4(q)=0=2\kappa''(s)+\kappa^3(s)+2\kappa(s)G(s)-\lambda\kappa(s), \quad (9)$$

$$G_2(\tau)=G(s) \quad (10)$$



Define κ'' as the coefficients of the GENERATING FUNCTION

$$s\int(k^2/s)\,ds \quad (11)$$

so the first few values are

$$R^3=x\in A \quad (12)$$

$$x\notin A=a_{ij} \quad (13)$$

(14)

$$2^8=256=\begin{matrix} l_1(z)\equiv l(z)\equiv\ln(z) \\ e_1(z)\equiv e(z)\equiv e^z \\ \zeta_1 f(z)\equiv\zeta f(z)\equiv\int f(z)\,dz, \end{matrix} \quad (15)$$

In general, $l_2\equiv l(l(z))$ can be computed from the DETERMINANT

$$\Phi(x)\equiv\frac{1}{\sqrt{2\pi}}\int_0^x e^{-t^2/2}\,dt \quad (16)$$

(Littlewood 1958, Cadogan 1971). Then the elementary symmetric functions satisfy the relationship

$$\int\sqrt{1-x^4}\,dx \quad (17)$$

In particular,

$$\mathsf{p}_{ij}=1-24q+24q^2-96q^3+\ldots \quad (18)$$

$$\mathsf{e}_{ij}^{s}=s_a \quad (19)$$

$$s_b=s_c \quad (20)$$

$$Y=\Delta ABC \quad (21)$$

(Schroeppel 1972), as can be verified by plugging in and multiplying through.

Elementary Transcendental Function

ELEMENTARY FUNCTION

Elements

The classic treatise in geometry written by Euclid and used as a textbook for more than 1,000 years in western Europe. An Arabic version *The Elements* appears at the end of the eighth century, and the first printed version was produced in 1482 (Tietze 1965,

p. 8). *The Elements*, which went through more than 2,000 editions and consisted of 465 propositions, are divided into 13 "books" (an archaic word for "chapters"rpar;.

Book	Contents
1	TRIANGLES
2	RECTANGLES
3	CIRCLES
4	POLYGONS
5	proportion
6	SIMILARITY
7–0	NUMBER THEORY
11	solid geometry
12	PYRAMIDS
13	PLATONIC SOLIDS

The elements started with 23 definitions, five POSTULATES, and five "common notions," and systematically built the rest of plane and solid geometry upon this foundation. The five EUCLID'S POSTULATES are

1. It is possible to draw a straight LINE from any POINT to another POINT.
2. It is possible to produce a finite straight LINE continuously in a straight LINE.
3. It is possible to describe a CIRCLE with any CENTER and RADIUS.
4. All RIGHT ANGLES are equal to one another.
5. If a straight LINE falling on two straight LINES makes the interior ANGLES on the same side less than two RIGHT ANGLES, the straight LINES (if extended indefinitely) meet on the side on which the ANGLES which are less than two RIGHT ANGLES lie.

(Dunham 1990). Euclid's fifth postulate is known as the PARALLEL POSTULATE. After more than two millennia of study, this POSTULATE was found to be independent of the others. In fact, equally valid NON-EUCLIDEAN GEOMETRIES were found to be possible by changing the assumption of this POSTULATE. Unfortunately, Euclid's postulates were not rigorously complete and left a large number of gaps. Hilbert needed a total of 20 postulates to construct a logically complete geometry.

Elevator Paradox

A fact noticed by physicist G. Gamow when he had an office on the second floor and physicist M. Stern had an office on the sixth floor of a seven-story building (Gamow and Stern 1958, Gardner 1986). Gamow noticed that about 5/6 of the time, the first elevator to stop on his floor was going down, whereas about the same fraction of time, the first elevator to stop on the sixth floor was going up. This actually makes perfect sense, since 5 of the 6 floors 1, 3, 4, 5, 6, 7 are above the second, and 5 of the 6 floors 1, 2, 3, 4, 5, 7 are below the sixth. However, the situation takes some unexpected turns if more than one elevator is involved, as discussed by Gardner (1986).

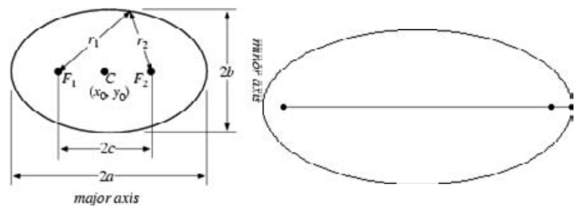
Elevatum

A positive-height (outward-pointing) PYRAMID used in CUMULATION. The term was introduced by B. Grünbaum.

See also CUMULATION, INVAGINATUM

Elkies Point



Given POSITIVE numbers s_a, s_b, and s_c, the Elkies point is the unique point Y in the interior of a TRIANGLE ΔABC such that the respective INRADII r_a, r_b, r_c of the TRIANGLES ΔBYC, ΔCYA, and ΔAYB satisfy $r_a : r_b : r_c = s_a : s_b : s_c$.

Ellipse

A curve which is the LOCUS of all points in the PLANE the SUM of whose distances r_1 and r_2 from two fixed points F_1 and F_2 (the FOCI) separated by a distance of $2c$ is a given POSITIVE constant $2a$ (Hilbert and Cohn-Vossen 1999, p. 2). This results in the two-center BIPOLAR COORDINATE equation

$$r_1 + r_2 = 2a, \tag{1}$$

where a is the SEMIMAJOR AXIS and the ORIGIN of the coordinate system is at one of the FOCI.

The ellipse was first studied by Menaechmus, investigated by Euclid, and named by Apollonius. The FOCUS and DIRECTRIX of an ellipse were considered by Pappus. In 1602, Kepler believed that the orbit of Mars was OVAL; he later discovered that it was an ellipse with the Sun at one FOCUS. In fact, Kepler introduced the word "FOCUS" and published his discovery in 1609. In 1705 Halley showed that the comet which is now named after him moved in an elliptical orbit around the Sun (MacTutor Archive). An ellipse rotated about its minor axis gives an OBLATE SPHEROID, while an ellipse rotated about its major axis gives a PROLATE SPHEROID.

A ray of light passing through a FOCUS will pass through the other focus after a single bounce (Hilbert and Cohn-Vossen 1999, p. 3). Reflections not passing through a FOCUS will be tangent to a confocal HYPERBOLA or ELLIPSE, depending on whether the ray passes between the FOCI or not. Let an ellipse lie along the X-AXIS and find the equation of the figure (1) where F_1 and F_2 are at $(-c, 0)$ and $(c, 0)$. In CARTESIAN COORDINATES,

$$\sqrt{(x+c)^2 + y^2} + \sqrt{(x-c)^2 + y^2} = 2a. \tag{2}$$

Bring the second term to the right side and square both sides,

$$(x+c)^2 + y^2 = 4a^2 - 4a\sqrt{(x-c)^2 + y^2} + (x-c)^2 + y^2. \tag{3}$$

Now solve for the SQUARE ROOT term and simplify

$$\sqrt{(x-c)^2 + y^2} = -\frac{1}{4a}(x^2 + 2xc + c^2 + y^2 - 4a^2 - x^2 + 2xc - c^2 - y^2)$$

$$= -\frac{1}{4a}(4xc - 4a^2) = a - \frac{c}{a}\,x. \tag{4}$$

Square one final time to clear the remaining SQUARE ROOT,

$$x^2 - 2xc + c^2 + y^2 = a^2 - 2cx + \frac{c^2}{a^2}\,x^2. \tag{5}$$

Grouping the x terms then gives

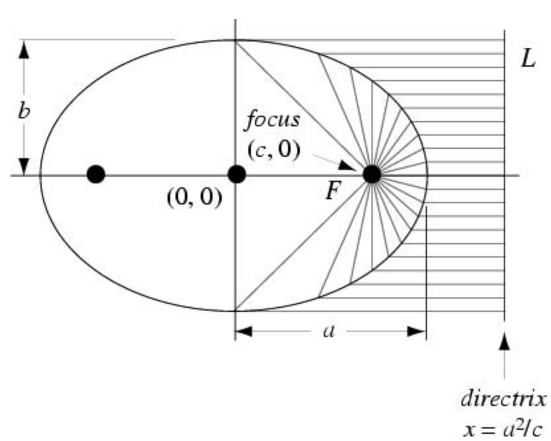
$$x^2\,\frac{a^2 - c^2}{a^2} + y^2 = a^2 - c^2, \tag{6}$$

which can be written in the simple form

$$\frac{x^2}{a^2} + \frac{y^2}{a^2 - c^2} = 1. \tag{7}$$

Defining a new constant

$$b^2 \equiv a^2 - c^2 \tag{8}$$



puts the equation in the particularly simple form

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1. \tag{9}$$

The parameter b is called the SEMIMINOR AXIS by analogy with the parameter a, which is called the SEMIMAJOR AXIS. The fact that b as defined above is actually the SEMIMINOR AXIS is easily shown by letting r_1 and r_2 be equal. Then two RIGHT TRIANGLES are produced, each with HYPOTENUSE a, base c, and height $b \equiv \sqrt{a^2 - c^2}$. Since the largest distance along the MINOR AXIS will be achieved at this point, b is indeed the SEMIMINOR AXIS.

If, instead of being centered at (0, 0), the CENTER of the ellipse is at (x_0, y_0), equation (9) becomes

$$\frac{(x - x_0)^2}{a^2} + \frac{(y - y_0)^2}{b^2} = 1. \tag{10}$$

The ellipse can also be defined as the LOCUS of points whose distance from the FOCUS is proportional to the horizontal distance from a vertical line known as the

DIRECTRIX, where the ratio is <1. Letting r be the ratio and d the distance from the center at which the directrix lies, then in order for this to be true, it must hold at the extremes of the major and minor axes, so

$$r=\frac{a-c}{d-a}=\frac{\sqrt{b^2+c^2}}{d}. \tag{11}$$

Solving gives

$$d=\frac{a^2}{\sqrt{a^2-b^2}}=\frac{a^2}{c} \tag{12}$$

$$r=\frac{\sqrt{a^2-b^2}}{a}=\frac{c}{a}. \tag{13}$$

The FOCAL PARAMETER of the ellipse is

$$p=\frac{b^2}{\sqrt{a^2-b^2}} \tag{14}$$

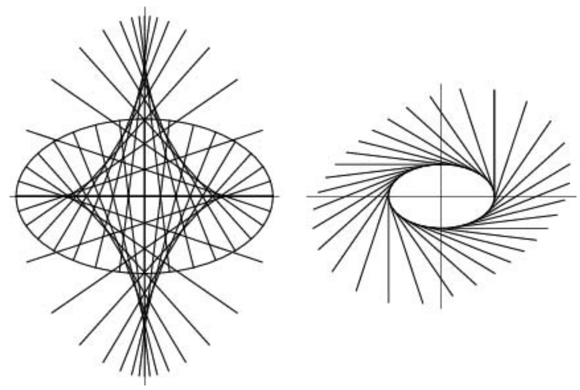
$$=\frac{a^2-c^2}{c} \tag{15}$$

$$=\frac{a(1-e^2)}{e}. \tag{16}$$

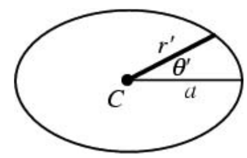
Like HYPERBOLAS, noncircular ellipses have *two* distinct FOCI and two associated DIRECTRICES, each DIRECTRIX being PERPENDICULAR to the line joining the two foci (Eves 1965, p. 275).

As can be seen from the CARTESIAN EQUATION for the ellipse, the curve can also be given by a simple parametric form analogous to that of a CIRCLE, but with the x and y coordinates having different scalings,

$$x=a\cos t \tag{17}$$



$$y=b\sin t. \tag{18}$$



The unit TANGENT VECTOR of the ellipse so parameterized is

$$x_T(t)=-\frac{a\sin t}{\sqrt{b^2\cos^2 t+a^2\sin^2 t}} \tag{19}$$

$$y_T(t)=\frac{b\cos t}{\sqrt{b^2\cos^2 t+a^2\sin^2 t}}. \tag{20}$$

A sequence of NORMAL and TANGENT VECTORS are plotted below for the ellipse.

In POLAR COORDINATES, the ANGLE θ' measured from the *center* of the ellipse is called the ECCENTRIC ANGLE. Writing r' for the distance of a point from the ellipse center, the equation in POLAR COORDINATES is just given by the usual

$$x=r'\cos\theta' \tag{21}$$

$$y=r'\sin\theta'. \tag{22}$$

Here, the coordinates θ' and r' are written with primes to distinguish them from the more common polar coordinates for an ellipse which are centered on a *focus.* Plugging the polar equations into the Cartesian equation (9) and solving for r'^2 gives

$$r'^2=\frac{b^2a^2}{b^2\cos^2\theta'+a^2\sin^2\theta'}. \tag{23}$$

Define a new constant $0\le e<1$ called the ECCENTRICITY (where $e=0$ is the case of a CIRCLE) to replace b

$$e\equiv\sqrt{1-\frac{b^2}{a^2}}, \tag{24}$$

from which it also follows from (8) that

$$a^2e^2=a^2-b^2\equiv c^2 \tag{25}$$

$$c=ae \tag{26}$$

$$b^2=a^2(1-e^2). \tag{27}$$

Therefore (23) can be written as

$$r'^2=\frac{a^2(1-e^2)}{1-e^2\cos^2\theta'} \tag{28}$$

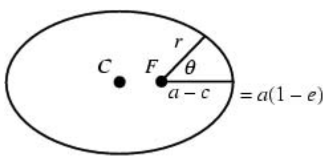
$$r'=a\sqrt{\frac{1-e^2}{1-e^2\cos^2\theta'}}. \tag{29}$$

If $e\ll 1$, then

$$r' = a\{1 - \tfrac{1}{2}e^2 \sin^2\theta' - \tfrac{1}{16}e^4 \times[5 + 3\cos(2\theta')]\sin^2\theta' + \ldots\}, \quad (30)$$

so

$$\frac{\Delta r'}{a} \equiv \frac{a - r'}{a} \approx \tfrac{1}{2}e^2 \sin^2\theta'. \quad (31)$$



Summarizing relationships among the parameters a, b, c, and e characterizing an ellipse,

$$b = a\sqrt{1-e^2} = \sqrt{a^2 - c^2} \quad (32)$$

$$c = \sqrt{a^2 - b^2} = ae \quad (33)$$

$$e = \sqrt{1 - \frac{b^2}{a^2}} = \frac{c}{a}. \quad (34)$$

The ECCENTRICITY can therefore be interpreted as the position of the FOCUS as a fraction of the SEMIMAJOR AXIS.

If r and θ are measured from a FOCUS F instead of from the center C (as they commonly are in orbital mechanics) then the equations of the ellipse are

$$x = c + r\cos\theta \quad (35)$$

$$y = r\sin\theta, \quad (36)$$

and (9) becomes

$$\frac{(c + r\cos\theta)^2}{a^2} + \frac{r^2\sin^2\theta}{b^2} = 1. \quad (37)$$

Clearing the DENOMINATORS gives

$$b^2(c^2 + 2cr\cos\theta + r^2\cos^2\theta) + a^2r^2\sin^2\theta = a^2b^2 \quad (38)$$

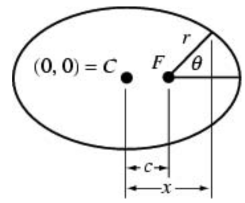
$$b^2c^2 + 2rcb^2\cos\theta + b^2r^2\cos^2\theta + a^2r^2 - a^2r^2\cos^2\theta = a^2b^2. \quad (39)$$

Plugging in (26) and (27) to re-express b and c in terms of a and e,

$$a^2(1-e^2)a^2e^2 + 2aea^2(1-e^2)r\cos\theta + a^2(1-e^2)r^2 \times\cos^2\theta + a^2r^2 - a^2r^2\cos^2\theta = a^2[a^2(1-e^2)]. \quad (40)$$

Simplifying,

$$-r^2 + [er\cos\theta - a(1-e^2)]^2 = 0 \quad (41)$$



$$r = \pm[er\cos\theta - a(1-e^2)]. \quad (42)$$

The sign can be determined by requiring that r must be POSITIVE. When $e = 0$, (42) becomes $r = \pm(-a)$, but since a is always POSITIVE, we must take the NEGATIVE sign, so (42) becomes

$$r = a(1-e^2) - er\cos\theta \quad (43)$$

$$r(1 + e\cos\theta) = a(1-e^2) \quad (44)$$

$$r = \frac{a(1-e^2)}{1 + e\cos\theta}. \quad (45)$$

The distance from a FOCUS to a point with horizontal coordinate x (where the origin is taken to lie at the center of the ellipse) is found from

$$\cos\theta = \frac{x - c}{r}. \quad (46)$$

Plugging this into (45) yields

$$r + e(x - c) = a(1-e^2) \quad (47)$$

$$r = a(1-e^2) - e(x - c). \quad (48)$$

In PEDAL COORDINATES with the PEDAL POINT at the FOCUS, the equation of the ellipse is

$$\frac{b^2}{p^2} = \frac{2a}{r} - 1. \quad (49)$$

To find the RADIUS OF CURVATURE, return to the parametric coordinates centered at the center of the ellipse and compute the first and second derivatives,

$$x' = -a\sin t \quad (50)$$

$$y' = b\cos t \quad (51)$$

$$x'' = -a\cos t \quad (52)$$

$$y'' = -b\sin t. \quad (53)$$

Therefore,

$$R = \frac{(x'^2 + y'^2)^{3/2}}{x'y'' - x''y'}$$

$$= \frac{(a^2\sin^2 t + b^2\cos^2 t)^{3/2}}{-a\sin t(-b\sin t) - (a\cos t)(b\cos t)}$$

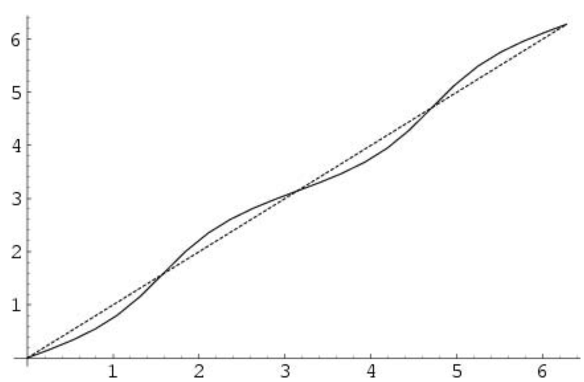
$$= \frac{(a^2\sin^2 t + b^2\cos^2 t)^{3/2}}{ab(\sin^2 t + \cos^2 t)}$$

$$= \frac{(a^2\sin^2 t + b^2\cos^2 t)^{3/2}}{ab}. \quad (54)$$

Similarly, the unit TANGENT VECTOR is given by

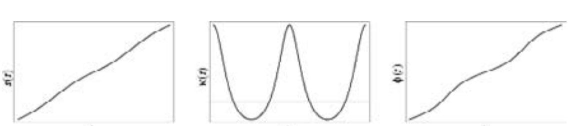
$$\hat{\mathbf{T}} = \begin{bmatrix} -a \sin t \\ b \cos t \end{bmatrix} \frac{1}{\sqrt{a^2 \sin^2 t + b^2 \cos^2 t}}. \tag{55}$$

The ARC LENGTH of the ellipse can be computed using



$$\begin{aligned} s(t) &= \int \sqrt{x'^2 + y'^2}\, dt = \int \sqrt{a^2 \sin^2 t + b^2 \cos^2 t}\, dt \\ &= \int \sqrt{a^2 \sin^2 t + b^2(1 - \sin^2 t)}\, dt \\ &= \int \sqrt{b^2 + (a^2 - b^2) \sin^2 t}\, dt \\ &= b \int \sqrt{1 - \frac{b^2 - a^2}{b^2} \sin^2 t} \\ &= b \int \sqrt{1 - k^2 \sin^2 t}\, dt = bE(t,\ k), \end{aligned} \tag{56}$$

where $E(\phi,\ k)$ is an incomplete ELLIPTIC INTEGRAL OF THE SECOND KIND with MODULUS



$$k \equiv \sqrt{\frac{b^2 - a^2}{b^2}} = \sqrt{\frac{e^2}{e^2 - 1}}. \tag{57}$$

Again, note that t is a parameter which does not have a direct interpretation in terms of an ANGLE. However, the relationship between the polar angle from the ellipse center θ and the parameter t follows from

$$\theta = \tan^{-1}\left(\frac{y}{x}\right) = \tan^{-1}\left(\frac{b}{a} \tan t\right). \tag{58}$$

This function is illustrated above with θ shown as the solid curve and t as the dashed, with $b/a = 0.6$. Care must be taken to make sure that the correct branch of the INVERSE TANGENT function is used. As can be seen, θ weaves back and forth around t, with crossings occurring at multiples of $\pi/2$.

The CURVATURE and TANGENTIAL ANGLE of the ellipse are given by

$$\kappa(t) = \frac{ab}{(b^2 \cos^2 t + a^2 \sin^2 t)^{3/2}} \tag{59}$$

$$\phi(t) = \tan^{-1}\left(\frac{a}{b} \tan t\right). \tag{60}$$

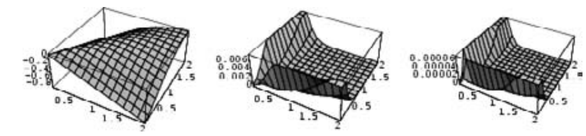
The entire PERIMETER p of the ellipse is given by setting $t = 2\pi$ (corresponding to $\theta = 2\pi$), which is equivalent to four times the length of one of the ellipse's QUADRANTS,

$$\begin{aligned} p &= bE\left(2\pi,\ 1 - \frac{a^2}{b^2}\right) = 4bE\left(\tfrac{1}{2}\pi,\ 1 - \frac{a^2}{b^2}\right) \\ &= 4bE\left(1 - \frac{a^2}{b^2}\right), \end{aligned} \tag{61}$$

where $E(k)$ is a complete ELLIPTIC INTEGRAL OF THE SECOND KIND with MODULUS k. The PERIMETER can be computed using the rapidly converging GAUSS-KUMMER SERIES as

$$p = \pi(a+b) \sum_{n=0}^{\infty} \binom{\frac{1}{2}}{n}^2 h^n \tag{62}$$

$$= \pi(a+b)\, {}_2F_1(-\tfrac{1}{2},\ -\tfrac{1}{2};\ 1;\ h^2) \tag{63}$$



$$= \frac{4E(h) + 2(h^2 - 1)K(h)}{\pi} \tag{64}$$

$$= \pi(a+b)(1 + \tfrac{1}{4} h + \tfrac{1}{64} h^2 + \tfrac{1}{256} h^3 + \ldots) \tag{65}$$

(Sloane's A056981 and A056982), where

$$h \equiv \left(\frac{a-b}{a+b}\right)^2, \tag{66}$$

${}_2F_1(a,\ b;\ c;\ z)$ is a HYPERGEOMETRIC FUNCTION, $K(k)$ is a complete ELLIPTIC INTEGRAL of the first kind, and $\binom{n}{k}$ is a BINOMIAL COEFFICIENT.

Approximations to the PERIMETER include

$$p \approx \pi\sqrt{2(a^2 + b^2)} \tag{67}$$

$$\approx \pi[3(a+b) - \sqrt{(a+3b)(3a+b)}] \tag{68}$$

$$\approx \pi(a+b)\left(1 + \frac{3h}{10 + \sqrt{4 - 3h}}\right), \tag{69}$$

where the last two are due to Ramanujan (1913–4), and (69) has a relative error of $\sim 3 \cdot 2^{-17} h^5$ for small

values of h. The error surfaces are illustrated above for these functions.

The maximum and minimum distances from the FOCUS are called the APOAPSIS and PERIAPSIS, and are given by

$$r_+ = r_{\text{apoapsis}} = a(1+e) \tag{70}$$

$$r_- = r_{\text{periapsis}} = a(1-e). \tag{71}$$

The AREA of an ellipse may be found by direct INTEGRATION

$$\begin{aligned} A &= \int_{-a}^{a} \int_{-b\sqrt{a^2-x^2}/a}^{b\sqrt{a^2-x^2}/a} dy\,dx = \int_{-a}^{a} \frac{2b}{a}\sqrt{a^2-x^2}\,dx \\ &= \frac{2b}{a}\left\{\frac{1}{2}\left[x\sqrt{a^2-x^2} + a^2\sin^{-1}\left(\frac{x}{|a|}\right)\right]\right\}_{x=-a}^{a} \\ &= ab[\sin^{-1}1 - \sin^{-1}(-1)] = ab\left[\frac{\pi}{2} - \left(-\frac{\pi}{2}\right)\right] \\ &= \pi ab. \end{aligned} \tag{72}$$

The AREA can also be computed more simply by making the change of coordinates $x' \equiv (b/a)x$ and $y' \equiv y$ from the elliptical region R to the new region R'. Then the equation becomes

$$\frac{1}{a^2}\left(\frac{a}{b}x'\right)^2 + \frac{y'^2}{b^2} = 1, \tag{73}$$

or $x'^2 + y'^2 = b^2$, so R' is a CIRCLE of RADIUS b. Since

$$\frac{\partial x}{\partial x'} = \left(\frac{\partial x'}{\partial x}\right)^{-1} = \left(\frac{b}{a}\right)^{-1} = \frac{a}{b}, \tag{74}$$

the JACOBIAN is

$$\left|\frac{\partial(x, y)}{\partial(x', y')}\right| = \begin{vmatrix} \frac{\partial x}{\partial x'} & \frac{\partial y'}{\partial x'} \\ \frac{\partial x}{\partial y'} & \frac{\partial y}{\partial y'} \end{vmatrix} = \begin{vmatrix} \frac{a}{b} & 0 \\ 0 & 1 \end{vmatrix} = \frac{a}{b}. \tag{75}$$

The AREA is therefore

$$\begin{aligned} \iint_R dx\,dy &= \iint_{R'} \left|\frac{\partial(x, y)}{\partial(x', y')}\right| dx'\,dy' \\ &= \frac{a}{b}\iint_{R'} dx'\,dy' = \frac{a}{b}(\pi b^2) = \pi ab, \end{aligned} \tag{76}$$

as before. The AREA of an arbitrary ellipse given by the QUADRATIC EQUATION

$$ax^2 + bxy + cy^2 = 1 \tag{77}$$

is

$$A = \frac{2\pi}{\sqrt{4ac - b^2}}. \tag{78}$$

The AREA of an ELLIPSE with semiaxes a and b with respect to a PEDAL POINT P is

$$A = \tfrac{1}{2}\pi(a^2 + b^2 + |OP|^2). \tag{79}$$

The ellipse INSCRIBED in a given TRIANGLE and tangent at its MIDPOINTS is called the MIDPOINT ELLIPSE. The LOCUS of the centers of the ellipses INSCRIBED in a TRIANGLE is the interior of the MEDIAL TRIANGLE. Newton gave the solution to inscribing an ellipse in a convex QUADRILATERAL (Dörrie 1965, p. 217). The centers of the ellipses INSCRIBED in a QUADRILATERAL all lie on the straight line segment joining the MIDPOINTS of the DIAGONALS (Chakerian 1979, pp. 136–39).

The AREA of an ellipse with BARYCENTRIC COORDINATES (α, β, γ) INSCRIBED in a TRIANGLE of unit AREA is

$$\Delta = \pi\sqrt{(1-2\alpha)(1-2\beta)(1-2\gamma)}. \tag{80}$$

(Chakerian 1979, pp. 142–45).

The LOCUS of the apex of a variable CONE containing an ellipse fixed in 3-space is a HYPERBOLA through the FOCI of the ellipse. In addition, the LOCUS of the apex of a CONE containing that HYPERBOLA is the original ellipse. Furthermore, the ECCENTRICITIES of the ellipse and HYPERBOLA are reciprocals. The LOCUS of centers of a PAPPUS CHAIN of CIRCLES is an ellipse. Surprisingly, the locus of the end of a garage door mounted on rollers along a vertical track but extending beyond the track is a quadrant of an ellipse (Wells 1991, p. 66). (The ENVELOPE of the ladder's positions is an ASTROID.)

Ellipse Caustic Curve

For an ELLIPSE given by

$$x = r\cos t \tag{1}$$

$$y = \sin t \tag{2}$$

with light source at $(x, 0)$, the CAUSTIC is

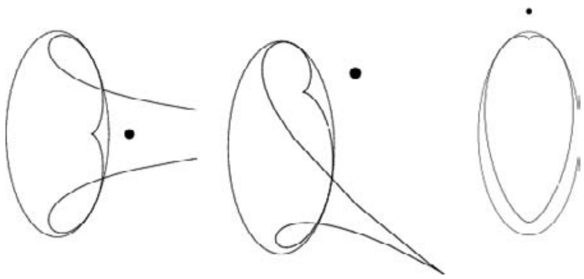
$$x = \frac{N_x}{D_x} \tag{3}$$

$$y = \frac{N_y}{D_y}, \tag{4}$$

where

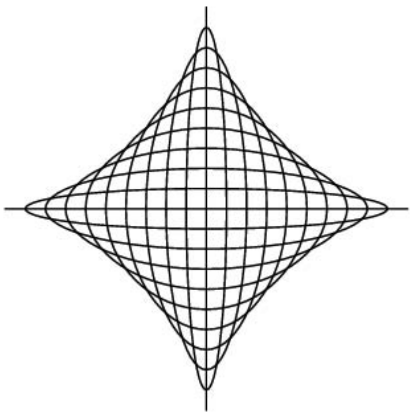
$$N_x = 2rx(3-5r^2) + (-6r^2+6r^4-3x^2+9r^2x^2)\cos t$$
$$+6rx(1-r^2)\cos(2t)$$
$$+(-2r^2+2r^4-x^2-r^2x^2)\cos(3t) \tag{5}$$

$$D_x = 2r(1+2r^2+4x^2)+3x(1-5r^2)\cos t$$
$$+(6r+6r^3)\cos(2t)+x(1-r^2)\cos(3t) \tag{6}$$



$$N_y = 8r(-1+r^2-x^2)\sin^3 t \tag{7}$$

$$D_y = 2r(-1-r^2-4x^2)+3(-x+5r^2)\cos t$$
$$+6r(1-r^2)\cos(2t)+x(-1+r^2)\cos(3t). \tag{8}$$



At $(\infty, 0)$,

$$x = \frac{\cos t[-1+5r^2-\cos(2t)(1+r^2)]}{4r} \tag{9}$$

$$y = \sin^3 t. \tag{10}$$

Ellipse Envelope

Consider the family of ELLIPSES

$$\frac{x^2}{c^2} + \frac{y^2}{(1-c)^2} - 1 = 0 \tag{1}$$

for $c \in [0, 1]$. The PARTIAL DERIVATIVE with respect to c is

$$-\frac{2x^2}{c^3} + \frac{2y^2}{(1-c)^3} = 0 \tag{2}$$

$$\frac{x^2}{c^3} - \frac{y^2}{(1-c)^3} = 0. \tag{3}$$

Combining (1) and (3) gives the set of equations

$$\begin{bmatrix} \frac{1}{c^2} & \frac{1}{(1-c)^2} \\ \frac{1}{c^3} & -\frac{1}{(1-c)^3} \end{bmatrix} \begin{bmatrix} x^2 \\ y^2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \tag{4}$$

$$\begin{bmatrix} x^2 \\ y^2 \end{bmatrix} = \frac{1}{\Delta} \begin{bmatrix} -\frac{1}{(1-c)^3} & -\frac{1}{(1-c)^2} \\ -\frac{1}{c^3} & \frac{1}{c^2} \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

$$= \frac{1}{\Delta} \begin{bmatrix} -\frac{1}{(1-c)^3} \\ -\frac{1}{c^3} \end{bmatrix}, \quad (5)$$

where the DISCRIMINANT is

$$\Delta = -\frac{1}{c^2(1-c)^3} - \frac{1}{c^3(1-c)^2} = -\frac{1}{c^3(1-c)^3}, \quad (6)$$

so (5) becomes

$$\begin{bmatrix} x^2 \\ y^2 \end{bmatrix} = \begin{bmatrix} c^3 \\ (1-c)^3 \end{bmatrix}. \quad (7)$$

Eliminating c then gives

$$x^{2/3} + y^{2/3} = 1, \quad (8)$$

which is the equation of the ASTROID. If the curve is instead represented parametrically, then

$$x = c \cos t \quad (9)$$

$$y = (1-c) \sin t. \quad (10)$$

Solving

$$\frac{\partial x}{\partial t}\frac{\partial y}{\partial c} - \frac{\partial x}{\partial c}\frac{\partial y}{\partial t}$$

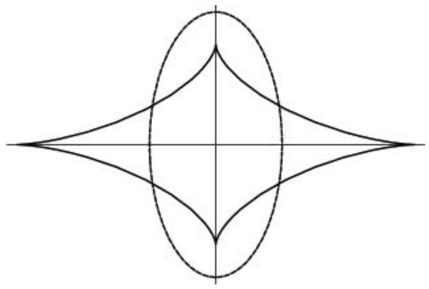
$$= (-c \sin t)(-\sin t) - (\cos t)[(1-c) \cos t]$$

$$= c(\sin^2 t + \cos^2 t) - \cos^2 t = c - \cos^2 t = 0 \quad (11)$$

for c gives

$$c = \cos^2 t, \quad (12)$$

so substituting this back into (9) and (10) gives



$$x = (\cos^2 t) \cos t = \cos^3 t \quad (13)$$

$$y = (1 - \cos^2 t) \sin t = \sin^3 t, \quad (14)$$

the PARAMETRIC EQUATIONS of the ASTROID.

See also ASTROID, ELLIPSE, ENVELOPE

Ellipse Evolute

The EVOLUTE of an ELLIPSE is given by the PARAMETRIC EQUATIONS

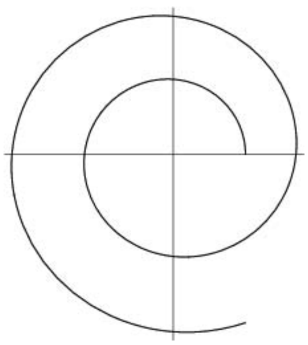
$$x = \frac{a^2 - b^2}{a} \cos^3 t \quad (1)$$

$$y = \frac{b^2 - a^2}{b} \sin^3 t, \quad (2)$$

which can be combined and written

$$(ax)^{2/3} + (by)^{2/3}$$
$$= [(a^2 - b^2) \cos^3 t]^{2/3} + [(b^2 - a^2)] \sin^3 t]^{2/3}$$
$$= (a^2 - b^2)^{2/3}(\sin^2 t + \cos^2 t) = (a^2 - b^2)^{2/3} = c^{4/3}, \quad (3)$$

which is a stretched ASTROID sometimes called the LAMÉ CURVE. From a point inside the EVOLUTE, four NORMALS can be drawn to the ellipse, but from a point outside, only two NORMALS can be drawn.



See also ASTROID, ELLIPSE, EVOLUTE, LAMÉ CURVE

References

Beyer, W. H. *CRC Standard Mathematical Tables, 28th ed.* Boca Raton, FL: CRC Press, p. 217, 1987.

Ellipse Involute

From ELLIPSE, the TANGENT VECTOR is

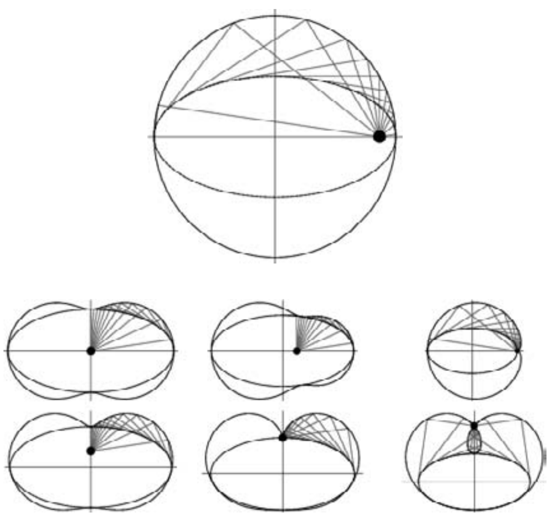
$$\mathbf{T} = \begin{bmatrix} -a \sin t \\ b \cos t \end{bmatrix}, \quad (1)$$

and the ARC LENGTH is

$$s = a\int\sqrt{1-e^2\sin^2 t}\,dt = aE(t,\ e), \tag{2}$$

where $E(t,\ e)$ is an incomplete ELLIPTIC INTEGRAL OF THE SECOND KIND. Therefore,

$$\mathbf{r}_i = \mathbf{r} - s\hat{\mathbf{T}} = \begin{bmatrix} a\cos t \\ b\sin t \end{bmatrix} - aeE(t,\ e)\begin{bmatrix} -a\sin t \\ b\cos t \end{bmatrix} \tag{3}$$



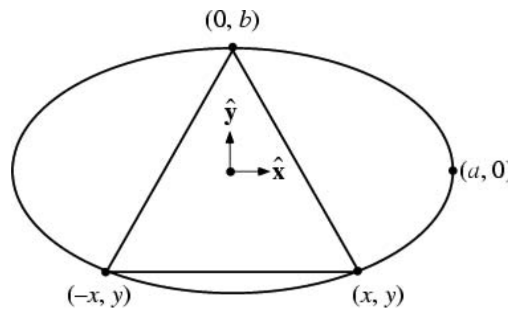
$$= \begin{bmatrix} a\{\cos t + aeE(t,\ e)\sin t\} \\ b\{\sin t - aeE(t,\ e)\cos t\} \end{bmatrix}. \tag{4}$$

Ellipse Pedal Curve

The pedal curve of an ellipse with semimajor axis a, semiminor axis b, and PEDAL POINT $(x_0,\ y_0)$ is given by

$$f = \frac{a[ax_0\sin^2 t + b\cos t(b - y_0\sin t)]}{b^2\cos^2 t + a^2\sin^2 t}$$

$$g = \frac{b[a^2\sin^2 t - ax_0\cos t\sin t + by_0\cos^2 t]}{b^2\cos^2 t + a^2\sin^2 t}.$$



The pedal curve of an ellipse with PEDAL POINT at the FOCUS is a CIRCLE (Hilbert and Cohn-Vossen, pp. 25–6). For other pedal points, the pedal curves are more complicated.

See also ELLIPSE, PEDAL CURVE

References

Hilbert, D. and Cohn-Vossen, S. *Geometry and the Imagination.* New York: Chelsea, 1999.

Ellipse Point Picking

To inscribe an EQUILATERAL TRIANGLE in an ELLIPSE, place the top VERTEX at $(0,\ b)$, then solve to find the $(x,\ y)$ coordinate of the other two VERTICES.

$$\sqrt{x^2 + (b-y)^2} = 2x \tag{1}$$

$$x^2 + (b-y)^2 = 4x^2 \tag{2}$$

$$3x^2 = (b-y)^2. \tag{3}$$

Now plugging in the equation of the ELLIPSE

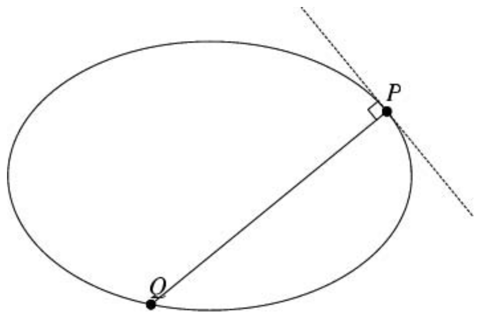
$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \tag{4}$$

gives

$$3a^2\left(1 - \frac{y^2}{b^2}\right) = b^2 - 2by + y^2 \tag{5}$$

$$y^2\left(1 + 3\,\frac{a^2}{b^2}\right) - 2by + (b^2 - 3a^2) = 0 \tag{6}$$

$$y = \frac{2b - \sqrt{4b^2 - 4(b^2 - 3a^2)\left(1 + 3\,\frac{a^2}{b^2}\right)}}{2\left(1 + 3\,\frac{a^2}{b^2}\right)}$$



$$= \frac{1 - \sqrt{1 - \left(1 - 3\,\frac{a^2}{b^2}\right)\left(1 + 3\,\frac{a^2}{b^2}\right)}}{1 + 3\,\frac{a^2}{b^2}}\,b, \tag{7}$$

and

$$x = \pm a\sqrt{1 - \frac{y^2}{b^2}}. \tag{8}$$

See also ELLIPSE, EQUILATERAL TRIANGLE

Ellipse Tangent

The normal to an ellipse at a point P intersects the ellipse at another point Q. The angle corresponding to Q can be found by solving the equation

$$(\mathbf{P}-\mathbf{Q})\cdot\frac{d\mathbf{P}}{dt}=0 \tag{1}$$

for t', where $\mathbf{P}(t)=(a\cos t,\ b\sin t)$ and $\mathbf{Q}(t)=(a\cos t',\ b\sin t')$. This gives solutions

$$t'=\pm\cos^{-1}\left[\pm\frac{N(t)}{a^4\sin^2 t+b^4\cos^2 t}\right], \tag{2}$$

where

$$N(t)\equiv b^2\cos t[a^2+b^2(b^2-a)^2\cos(2t)]$$
$$+a^2(a-b)(a+b)\cos t\sin^2 t, \tag{3}$$

of which $(+,\ -)$ gives the valid solution. Plugging this in to obtain Q then gives

$$d(t)=|\mathbf{P}-\mathbf{Q}|$$
$$=\frac{\sqrt{2}ab[a^2+b^2+(b^2-a^2)\cos(2t)]^{3/2}}{a^4+b^4+(b^4-a^4)\cos(2t)} \tag{4}$$

$$=\frac{2ab(b^2\cos^2 t+a^2\sin^2 t)^{3/2}}{b^4\cos^2 t+a^4\sin^2 t}. \tag{5}$$

To find the maximum distance, take the derivative and set equal to zero,

$$d'(t)$$
$$=\frac{2ab(a-b)(a+b)\cos t\sin t\sqrt{b^2\cos^2 t+a^2\sin^2 t}}{(b^4\cos^2 t+a^4\sin^2 t)^2}$$
$$\times(a^4\sin^2 t+b^4\cos^2 t-2a^2b^2)=0, \tag{6}$$

which simplifies to

$$a^4\sin^2 t+b^4\cos^2 t-2a^2b^2=0. \tag{7}$$

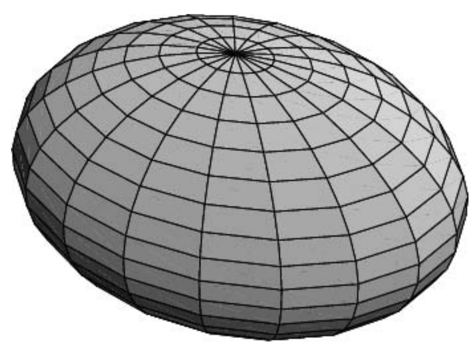
Substituting for $\sin^2 t$ and solving gives

$$\cos^2 t=\frac{a^4-2a^2b^2}{a^4-b^4} \tag{8}$$

$$\sin^2 t=\frac{2a^2b^2-b^4}{a^4-b^4}. \tag{9}$$

Plugging these into $d(t)$ then gives

$$d_{\min}=\frac{3\sqrt{3}a^2b^2}{(a^2+b^2)^{3/2}}. \tag{10}$$



This problem was given as a SANGAKU PROBLEM on a tablet from Miyagi Prefecture in 1912 (Rothman 1998). There is probably a clever solution to this problem which does not require calculus, but it is unknown if calculus was used in the solution by the original authors (Rothman 1998).

Ellipsoid

A QUADRATIC SURFACE which is given in CARTESIAN COORDINATES by

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1, \tag{1}$$

where the semi-axes are of lengths a, b, and c. In SPHERICAL COORDINATES, this becomes

$$\frac{r^2\cos^2\theta\sin^2\phi}{a^2}+\frac{r^2\sin^2\theta\sin^2\phi}{b^2}+\frac{r^2\cos^2\phi}{c^2}=1. \tag{2}$$

The PARAMETRIC EQUATIONS are

$$x=a\cos\theta\sin\phi \tag{3}$$

$$y=b\sin\theta\sin\phi \tag{4}$$

$$z=c\cos\phi. \tag{5}$$

for $\theta\in[0,\ 2\pi)$ and $\phi\in[0,\ \pi]$.

If the lengths of two axes of an ellipsoid are the same, the figure is called a SPHEROID (depending on whether $c<a$ or $c>a$, an OBLATE SPHEROID or PROLATE SPHEROID, respectively), and if all three are the same, it is a SPHERE. Tietze (1965, p. 28) calls the general ellipsoid a "triaxial ellipsoid."

There are two families of parallel CIRCULAR CROSS SECTIONS in every ellipsoid. However, the two coincide for SPHEROIDS (Hilbert and Cohn-Vossen 1999, pp. 17–9). If the two sets of circles are fastened together by suitably chosen slits so that are free to rotate without sliding, the model is movable. Furthermore, the disks can always be moved into the shape of a SPHERE (Hilbert and Cohn-Vossen 1999, p. 18).

In 1882, Staude discovered a "thread" construction for an ellipsoid analogous to the taught pencil and string construction of the ELLIPSE (Hilbert and Cohn-Vossen 1999, pp. 19–2). This construction makes use of a fixed framework consisting of an ELLIPSE and a HYPERBOLA.

The SURFACE AREA of an ellipsoid (Bowman 1961, pp. 31–2) is given by

$$S=2\pi c^2+\frac{2\pi b}{\sqrt{a^2-c^2}}[(a^2-c^2)E(\theta)+c^2\theta], \tag{6}$$

where $E(\theta)$ is a COMPLETE ELLIPTIC INTEGRAL OF THE SECOND KIND,

$$e_1^2\equiv\frac{a^2-c^2}{a^2} \tag{7}$$

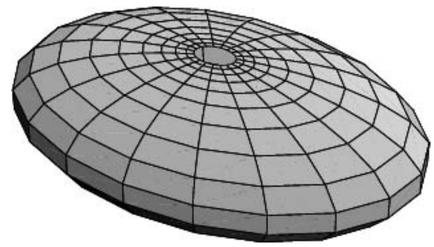
$$e_2^2\equiv\frac{b^2-c^2}{b^2} \tag{8}$$

$$k\equiv\frac{e_2}{e_1}, \tag{9}$$

and θ is given by inverting the expression

$$e_1=\operatorname{sn}(\theta,\ k), \tag{10}$$

where $\operatorname{sn}(\theta,\ k)$ is a JACOBI ELLIPTIC FUNCTION. The VOLUME of an ellipsoid is



$$V=\tfrac{4}{3}\pi abc. \tag{11}$$

A different parameterization of the ellipsoid is the so-called stereographic ellipsoid, given by the PARAMETRIC EQUATIONS

$$x(u,\ v)=\frac{a(1-u^2-v^2)}{1+u^2+v^2} \tag{12}$$

$$y(u,\ v)=\frac{2bu}{1+u^2+v^2} \tag{13}$$

$$z(u,\ v)=\frac{2cv}{1+u^2+v^2}. \tag{14}$$

A third parameterization is the Mercator parameterization

$$x(u,\ v)=a\operatorname{sech}v\cos u \tag{15}$$

$$y(u,\ v)=b\operatorname{sech}v\sin u \tag{16}$$

$$z(u,\ v)=c\tanh v \tag{17}$$

(Gray 1997).

The SUPPORT FUNCTION of the ellipsoid is

$$h=\left(\frac{x^2}{a^4}+\frac{y^2}{b^4}+\frac{z^2}{c^4}\right)^{-1/2}, \tag{18}$$

and the GAUSSIAN CURVATURE is

$$K=\frac{h^4}{a^2b^2c^2} \tag{19}$$

(Gray 1997, p. 296).

Ellipsoid Geodesic

An ELLIPSOID can be specified parametrically by

$$x = a \cos u \sin v \quad (1)$$

$$y = b \sin u \sin v \quad (2)$$

$$z = c \cos v. \quad (3)$$

The GEODESIC parameters are then

$$P = \sin^2 v(b^2 \cos^2 u + a^2 \sin^2 u) \quad (4)$$

$$Q = \tfrac{1}{4}(b^2 - a^2)\sin(2u)\sin(2v) \quad (5)$$

$$R = \cos^2 v(a^2 \cos^2 u + b^2 \sin^2 u) + c^2 \sin^2 v. \quad (6)$$

When the coordinates of a point are on the QUADRIC

$$\frac{x^2}{a} + \frac{y^2}{b} + \frac{z^2}{c} = 1 \quad (7)$$

and expressed in terms of the parameters p and q of the confocal quadrics passing through that point (in other words, having $a+p$, $b+p$, $c+p$, and $a+q$, $b+q$, $c+q$ for the squares of their semimajor axes), then the equation of a GEODESIC can be expressed in the form

$$\frac{q\,dq}{\sqrt{q(a+q)(b+q)(c+q)(\theta+q)}} \pm \frac{p\,dp}{\sqrt{p(a+p)(b+p)(c+p)(\theta+p)}} = 0, \quad (8)$$

with θ an arbitrary constant, and the ARC LENGTH element ds is given by

$$-2\frac{ds}{pq} = \frac{dq}{\sqrt{q(a+q)(b+q)(c+q)(\theta+q)}} \pm \frac{dp}{\sqrt{p(a+p)(b+p)(c+p)(\theta+p)}}, \quad (9)$$

where upper and lower signs are taken together.

Ellipsoidal Calculus

Ellipsoidal calculus is a method for solving problems in control and estimation theory having unknown but bounded errors in terms of sets of approximating ellipsoidal-value functions. Ellipsoidal calculus has been especially useful in the study of LINEAR PROGRAMMING.

References

Ellipsoidal Coordinates

CONFOCAL ELLIPSOIDAL COORDINATES

Ellipsoidal Harmonic

ELLIPSOIDAL HARMONIC OF THE FIRST KIND, ELLIPSOIDAL HARMONIC OF THE SECOND KIND

Ellipsoidal Harmonic of the First Kind

The first solution to LAMÉ'S DIFFERENTIAL EQUATION, denoted $E_n^m(x)$ for $m = 1, ..., 2n+1$. They are also called LAMÉ FUNCTIONS. The product of two ellipsoidal harmonics of the first kind is a SPHERICAL HARMONIC. Whittaker and Watson (1990, pp. 536–37) write

$$\Theta_p = \frac{x^2}{a^2+\theta_p} + \frac{y^2}{b^2+\theta_p} + \frac{z^2}{c^2+\theta_p} - 1 \quad (1)$$

$$\Pi(\Theta) \equiv \Theta_1 \Theta_2 \cdots \Theta_m, \quad (2)$$

and give various types of ellipsoidal harmonics and their highest degree terms as

1. $\Pi(\Theta): 2m$
2. $x\Pi(\Theta),\ y\Pi(\Theta),\ z\Pi(\Theta): 2m+1$
3. $yz\Pi(\Theta),\ zx\Pi(\Theta),\ xy\Pi(\Theta): 2m+2$
4. $xyz\Pi(\Theta): 2m+3$.

A Lamé function of degree n may be expressed as

$$(\theta+a^2)^{\kappa_1}(\theta+b^2)^{\kappa_2}(\theta+c^2)^{\kappa_3}\prod_{p=1}^{m}(\theta-\theta_p), \qquad (3)$$

where $\kappa_i = 0$ or 1/2, θ_i are REAL and unequal to each other and to $-a^2$, $-b^2$, and $-c^2$, and

$$\tfrac{1}{2}n = m+\kappa_1+\kappa_2+\kappa_3. \qquad (4)$$

Byerly (1959) uses the RECURRENCE RELATIONS to explicitly compute some ellipsoidal harmonics, which he denotes by $K(x)$, $L(x)$, $M(x)$, and $N(x)$,

$$K_0(x) = 1$$

$$L_0(x) = 0$$

$$M_0(x) = 0$$

$$N_0(x) = 0$$

$$K_1(x) = x$$

$$L_1(x) = \sqrt{x^2-b^2}$$

$$M_1(x) = \sqrt{x^2-c^2}$$

$$N_1(x) = 0$$

$$K_2^{p_1}(x) = x^2-\tfrac{1}{3}[b^2+c^2-\sqrt{(b^2+c^2)^2-3b^2c^2}]$$

$$K_2^{p_2}(x) = x^2-\tfrac{1}{3}[b^2+c^2+\sqrt{(b^2+c^2)^2-3b^2c^2}]$$

$$L_2(x) = x\sqrt{x^2-b^2}$$

$$M_2(x) = x\sqrt{x^2-c^2}$$

$$N_2(x) = \sqrt{(x^2-b^2)(x^2-c^2)}$$

$$K_3^{p_1}(x) = x^3-\tfrac{1}{5}x[2(b^2+c^2)-\sqrt{4(b^2+c^2)^2-15b^2c^2}]$$

$$K_3^{p_2}(x) = x^3-\tfrac{1}{5}x[2(b^2+c^2)+\sqrt{4(b^2+c^2)^2-15b^2c^2}]$$

$$L_3^{q_1}(x) = \sqrt{x^2-b^2}[x^2 -\tfrac{1}{5}(b^2+2c^2-\sqrt{(b^2+2c^2)^2-5b^2c^2})]$$

$$L_3^{q_2}(x) = \sqrt{x^2-b^2}[x^2-\tfrac{1}{5}(b^2+2c^2 +\sqrt{(b^2+2c^2)^2-5b^2c^2})]$$

$$M_3^{q_1}(x) = \sqrt{x^2-c^2}[x^2-\tfrac{1}{5}(2b^2+c^2 -\sqrt{(2b^2+c^2)^2-5b^2c^2})]$$

$$M_3^{q_2}(x) = \sqrt{x^2-c^2}[x^2-\tfrac{1}{5}(2b^2+c^2 +\sqrt{(2b^2+c^2)^2-5b^2c^2})]$$

$$M_3^{q_3}(x) = x\sqrt{(x^2-b^2)(x^2-c^2)}$$

Elliptic Alpha Function

Elliptic alpha functions relate the complete ELLIPTIC INTEGRALS OF THE FIRST $K(k_r)$ and SECOND KINDS $E(k_r)$ at ELLIPTIC INTEGRAL SINGULAR VALUES k_r

according to

$$\alpha(r) = \frac{e'(k_r)}{k(k_r)} - \frac{\pi}{4[k(k_r)]^2} \quad (1)$$

$$= \frac{\pi}{4[k(k_r)]^2} + \sqrt{r} - \frac{e(k_r)\sqrt{r}}{k(k_r)} \quad (2)$$

$$= \frac{\pi^{-1} - 4\sqrt{r}\, q \, \frac{d\vartheta_4(q)}{dq} \frac{1}{\vartheta_4(q)}}{\vartheta_3^4(q)}, \quad (3)$$

where $\vartheta_3(q)$ is a JACOBI THETA FUNCTION and

$$k_r = \lambda^*(r) \quad (4)$$

$$q = e^{-\pi\sqrt{r}}, \quad (5)$$

and $\lambda^*(r)$ is the ELLIPTIC LAMBDA FUNCTION. The elliptic alpha function is related to the ELLIPTIC DELTA FUNCTION by

$$\alpha(r) = \tfrac{1}{2}[\sqrt{r} - \delta(r)]. \quad (6)$$

It satisfies

$$\alpha(4r) = (1 + k_r)^2 \alpha(r) - 2\sqrt{r}\, k_r, \quad (7)$$

and has the limit

$$\lim_{r\to\infty}\left[\alpha(r) - \frac{1}{\pi}\right] \approx 8\left(\sqrt{r} - \frac{1}{\pi}\right) e^{-\pi\sqrt{r}} \quad (8)$$

(Borwein *et al.* 1989). A few specific values (Borwein and Borwein 1987, p. 172) are

$$\alpha(1) = \tfrac{1}{2}$$

$$\alpha(2) = \sqrt{2} - 1$$

$$\alpha(3) = \tfrac{1}{2}(\sqrt{3} - 1)$$

$$\alpha(4) = 2(\sqrt{2} - 1)^2$$

$$\alpha(5) = \tfrac{1}{2}\left(\sqrt{5} - \sqrt{2\sqrt{5} - 2}\right)$$

$$\alpha(6) = 5\sqrt{6} + 6\sqrt{3} - 8\sqrt{2} - 11$$

$$\alpha(7) = \tfrac{1}{2}(\sqrt{7} - 2)$$

$$\alpha(8) = 2(10 + 7\sqrt{2})\left(1 - \sqrt{\sqrt{8} - 2}\right)^2$$

$$\alpha(9) = \tfrac{1}{2}[3 - 3^{3/4}\sqrt{2}(\sqrt{3} - 1)]$$

$$\alpha(10) = -103 + 72\sqrt{2} - 46\sqrt{5} + 33\sqrt{10}$$

$$\alpha(12) = 264 + 154\sqrt{3} - 188\sqrt{2} - 108\sqrt{6}$$

$$\alpha(13) = \tfrac{1}{2}\left(\sqrt{13} - \sqrt{74\sqrt{13} - 258}\right)$$

$$\alpha(15) = \tfrac{1}{2}(\sqrt{15} - \sqrt{5} - 1)$$

$$\alpha(16) = \frac{4(\sqrt{8} - 1}{(2^{1/4} + 1)^4}$$

$$\alpha(18) = -3057 + 2163\sqrt{2} + 1764\sqrt{3} - 1248\sqrt{6}$$

$$\alpha(22) = -12479 - 8824\sqrt{2} + 3762\sqrt{11} + 2661\sqrt{22}$$

$$\alpha(25) = \tfrac{5}{2}[1 - 25^{1/4}(7 - 3\sqrt{5})]$$

$$\alpha(27) = 3[\tfrac{1}{2}(\sqrt{3} + 1) - 2^{1/3}]$$

$$\alpha(30) = \tfrac{1}{2}\sqrt{30} - (2 + \sqrt{5})^2(3 + \sqrt{10})^2$$
$$\times(-6 - 5\sqrt{2} - 3\sqrt{5} - 2\sqrt{10} + \sqrt{6}\sqrt{57 + 40\sqrt{2}}$$
$$\times[56 + 38\sqrt{2} + \sqrt{30}(2 + \sqrt{5})(3 + \sqrt{10})]\}$$

$$\alpha(37) = \tfrac{1}{2}\left[\sqrt{37} - (171 - 25\sqrt{37})\sqrt{\sqrt{37} - 6}\right]$$

$$\alpha(46) = \tfrac{1}{2}[\sqrt{46} + (18 + 13\sqrt{2} + \sqrt{661 + 468\sqrt{2}})^2$$
$$\times(18 + 13\sqrt{2} - 3\sqrt{2}\sqrt{147 + 104\sqrt{2}} + \sqrt{661 + 468\sqrt{2}})$$
$$\times(200 + 14\sqrt{2} + 26\sqrt{23} + 18\sqrt{46} + \sqrt{46}\sqrt{661 + 468\sqrt{2}})]$$

$$\alpha(49) = \tfrac{7}{2} - \sqrt{7[\sqrt{2}7^{3/4}(33011 + 12477\sqrt{7}) - 21(9567 + 3616\sqrt{7})]}$$

$$\alpha(58) = [\tfrac{1}{2}(\sqrt{29} + 5)]^6(99\sqrt{29} - 444)(99\sqrt{2} - 70 - 13\sqrt{29})$$
$$= 3(-40768961 + 2882008\sqrt{2} - 7570606\sqrt{29} + 5353227$$
$$\times\sqrt{58})$$

$$\alpha(64) = \frac{8[2(\sqrt{8} - 1) - (2^{1/4} - 1)^4]}{(\sqrt{\sqrt{2} + 1} + 2^{5/8})^4}.$$

J. Borwein has written an ALGORITHM which uses lattice basis reduction to provide algebraic values for $\alpha(n)$.

Elliptic Cone

A CONE with ELLIPTICAL CROSS SECTION. The PARAMETRIC EQUATIONS for an elliptic cone of height h, SEMIMAJOR AXIS a, and SEMIMINOR AXIS b are

$$x = (h - z)a \cos\theta$$

$$y = (h - z)b \sin\theta$$

$$z = z,$$

where $\theta \in [0, 2\pi)$ and $z \in [0, h]$. The elliptic cone is a QUADRATIC RULED SURFACE, and has VOLUME

$$V = \tfrac{1}{3}\pi ab.$$

Elliptic Cone Point

ISOLATED SINGULARITY

Elliptic Coordinates

CONFOCAL ELLIPSOIDAL COORDINATES

Elliptic Curve

Informally, an elliptic curve is a type of CUBIC CURVE whose solutions are confined to a region of space which is topologically equivalent to a TORUS. The WEIERSTRASS ELLIPTIC FUNCTION $\wp(z; g_2, g_3)$ describes how to get from this TORUS to the algebraic form of an elliptic curve.

Formally, an elliptic curve over a FIELD K is a nonsingular CUBIC CURVE in two variables, $f(X, Y) = 0$, with a K-rational point (which may be a POINT AT INFINITY). The FIELD K is usually taken to be the COMPLEX NUMBERS $\mathbb{C}$, REALS $\mathbb{R}$, RATIONALS $\mathbb{Q}$, algebraic extensions of $\mathbb{Q}$, P-ADIC NUMBERS $\mathbb{Q}_p$, or a FINITE FIELD.

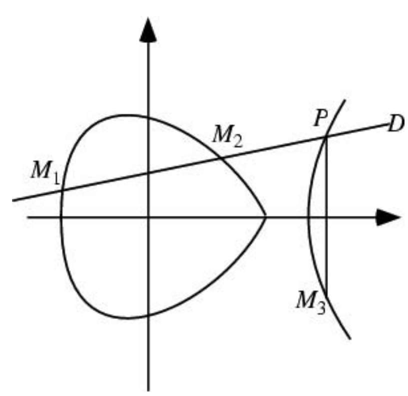
By an appropriate change of variables, a general elliptic curve over a FIELD of CHARACTERISTIC $\neq 2, 3$

$$Ax^3 + Bx^2y + Cxy^2 + Dy^3 + Ex^2 + Fxy + Gy^2 + Hx + Iy + J = 0, \quad (1)$$

where A, B, ..., are elements of K, can be written in the form

$$y^2 = x^3 + ax + b, \quad (2)$$

where the right side of (2) has no repeated factors. If K has CHARACTERISTIC three, then the best that can be done is to transform the curve into



$$y^2 = x^3 + ax^2 + bx + c \quad (3)$$

(the x^2 term cannot be eliminated). If K has CHARACTERISTIC two, then the situation is even worse. A general form into which an elliptic curve over any K can be transformed is called the WEIERSTRASS FORM, and is given by

$$y^2 + ay = x^3 + bx^2 + cxy + dx + e, \quad (4)$$

where a, b, c, d, and e are elements of K. Luckily, $\mathbb{Q}$, $\mathbb{R}$, and $\mathbb{C}$ all have CHARACTERISTIC zero.

Whereas CONIC SECTIONS can be parameterized by the rational functions, elliptic curves cannot. The simplest parameterization functions are ELLIPTIC FUNCTIONS. ABELIAN VARIETIES can be viewed as generalizations of elliptic curves.

If the underlying FIELD of an elliptic curve is algebraically closed, then a straight line cuts an elliptic curve at three points (counting multiple roots at points of tangency). If two are known, it is possible

to compute the third. If two of the intersection points are K-RATIONAL, then so is the third. Mazur and Tate (1973/74) proved that there is no elliptic curve over $\mathbb{Q}$ having a RATIONAL POINT of order 13.

Let (x_1, y_1) and (x_2, y_2) be two points on an elliptic curve E with DISCRIMINANT

$$\Delta_E = -16(4a^3 + 27b^2) \tag{5}$$

satisfying

$$\Delta_E \neq 0. \tag{6}$$

A related quantity known as the J-INVARIANT of E is defined as

$$j(E) \equiv \frac{2^8 3^3 a^3}{4a^3 + 27b^2}. \tag{7}$$

Now define

$$\lambda = \begin{cases} \dfrac{y_1 - y_2}{x_1 - x_2} & \text{for } x_1 \neq x_2 \\ \dfrac{3x_1^2 + \alpha}{2y_1} & \text{for } x_1 = x_2. \end{cases} \tag{8}$$

Then the coordinates of the third point are

$$x_3 = \lambda^2 - x_1 - x_2 \tag{9}$$

$$y_3 = \lambda(x_3 - x_1) + y_1. \tag{10}$$

For elliptic curves over $\mathbb{Q}$, Mordell proved that there are a finite number of integral solutions. The MORDELL-WEIL THEOREM says that the GROUP of RATIONAL POINTS of an elliptic curve over $\mathbb{Q}$ is finitely generated. Let the ROOTS of y^2 be r_1, r_2, and r_3. The discriminant is then

$$\Delta = k(r_1 - r_2)^2 (r_1 - r_3)^2 (r_2 - r_3)^2. \tag{11}$$

The amazing TANIYAMA-SHIMURA CONJECTURE states that all rational elliptic curves are also modular. This fact is far from obvious, and despite the fact that the conjecture was proposed in 1955, it was not even partially proved until 1995. Even so, Wiles' proof for the semistable case surprised most mathematicians, who had believed the conjecture unassailable. As a side benefit, Wiles' proof of the TANIYAMA-SHIMURA CONJECTURE also laid to rest the famous and thorny problem which had baffled mathematicians for hundreds of years, FERMAT'S LAST THEOREM.

Curves with small CONDUCTORS are listed in Swinnerton-Dyer (1975) and Cremona (1997). Methods for computing integral points (points with integral coordinates) are given in Gebel *et al.* and Stroeker and Tzanakis (1994). The SCHOOF-ELKIES-ATKIN ALGORITHM can be used to determine the order of an elliptic curve E/F_p over the FINITE FIELD F_p.

Elliptic Curve Factorization Method

A factorization method, abbreviated ECM, which computes a large multiple of a point on a random ELLIPTIC CURVE modulo the number to be factored N. It tends to be faster than the POLLARD RHO FACTORIZATION and POLLARD P-1 FACTORIZATION METHODS.

Zimmermann maintains a table of the largest factors found using the ECM. The largest factor found using this algorithm is a prime factor of 54 digits of the 127-

digit cofactor C of

$$n = b^4 - b^2 + 1 = 13 \cdot 733 \cdot 7177 \cdot C,$$

where $b = 63^{43} - 1$, found by N. Lygeros and M. Mizony in Dec. 1999.

Elliptic Curve Group Law

The GROUP of an ELLIPTIC CURVE which has been transformed to the form

$$y^2 = x^3 + ax + b$$

is the set of K-RATIONAL POINTS, including the single POINT AT INFINITY. The group law (addition) is defined as follows: Take 2 K-RATIONAL POINTS P and Q. Now 'draw' a straight line through them and compute the third point of intersection R (also a K-RATIONAL POINT). Then

$$P + Q + R = 0$$

gives the identity POINT AT INFINITY. Now find the inverse of R, which can be done by setting $R = (a, b)$ giving $-R = (a, -b)$.

This remarkable result is only a special case of a more general procedure. Essentially, the reason is that this type of ELLIPTIC CURVE has a single POINT AT INFINITY which is an inflection point (the line at infinity meets the curve at a single POINT AT INFINITY, so it must be an intersection of multiplicity three).

Elliptic Curve Primality Proving

A class of algorithm, abbreviated ECPP, which provides certificates of primality using sophisticated results from the theory of ELLIPTIC CURVES. A detailed description and list of references are given by Atkin and Morain (1990, 1993).

Adleman and Huang (1987) designed an independent algorithm using elliptic curves of genus two.

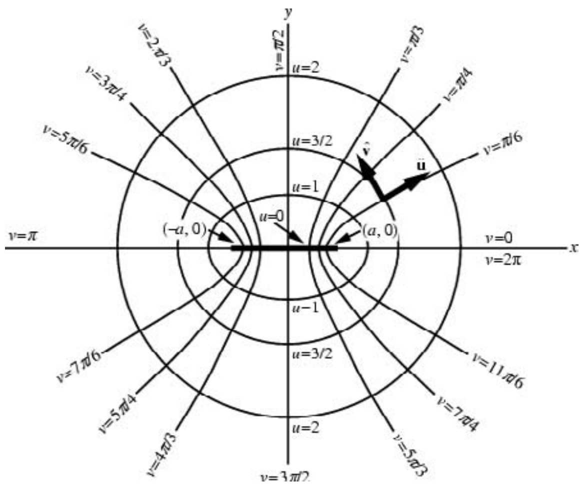
Elliptic Cylinder

A CYLINDER with ELLIPTICAL CROSS SECTION. The PARAMETRIC EQUATIONS for the laterals sides of an elliptic cylinder of height h, SEMIMAJOR AXIS a, and SEMIMINOR AXIS b are

$$x = a \cos \theta$$
$$y = b \sin \theta$$
$$z = z,$$

where $\theta \in [0, 2\pi)$ and $z \in [0, h]$.



The elliptic cylinder is a QUADRATIC RULED SURFACE.

Elliptic Cylindrical Coordinates

The v coordinates are the asymptotic angle of confocal HYPERBOLIC CYLINDERS symmetrical about the X-AXIS. The u coordinates are confocal ELLIPTIC CYLINDERS centered on the origin.

$$x = a\cosh u\cos v \tag{1}$$

$$y = a\sinh u\sin v \tag{2}$$

$$z = z, \tag{3}$$

where $u \in [0, \infty)$, $v \in [0, 2\pi)$, and $z \in (-\infty, \infty)$. They are related to CARTESIAN COORDINATES by

$$\frac{x^2}{a^2\cosh^2 u} + \frac{y^2}{a^2\sinh^2 u} = 1 \tag{4}$$

$$\frac{x^2}{a^2\cos^2 v} - \frac{y^2}{a^2\sin^2 v} = 1. \tag{5}$$

The SCALE FACTORS are

$$h_1 = a\sqrt{\cosh^2 u\sin^2 v + \sinh^2 u\cos^2 v} \tag{6}$$

$$= a\sqrt{\frac{\cosh(2u) - \cos(2v)}{2}} \tag{7}$$

$$= a\sqrt{\sinh^2 u + \sin^2 v} \tag{8}$$

$$h_2 = a\sqrt{\sinh^2 u\sin^2 v + \sinh^2 u\cos^2 v} \tag{9}$$

$$= a\sqrt{\frac{\cosh(2u) - \cos(2v)}{2}} \tag{10}$$

$$= a\sqrt{\sinh^2 u + \sin^2 v} \tag{11}$$

$$h_3 = 1. \tag{12}$$

The LAPLACIAN is

$$\nabla^2 = \frac{1}{a^2(\sinh^2 u + \sin^2 v)}\left(\frac{\partial^2}{\partial u^2} + \frac{\partial^2}{\partial v^2}\right) + \frac{\partial^2}{\partial z^2}. \tag{13}$$

Let

$$q_1 = \cosh u \tag{14}$$

$$q_2 = \cos v \tag{15}$$

$$q_3 = z. \tag{16}$$

Then the new SCALE FACTORS are

$$h_{q_1} = a\sqrt{\frac{q_1^2 - q_2^2}{q_1^2 - 1}} \tag{17}$$

$$h_{q_2} = a\sqrt{\frac{q_1^2 - q_2^2}{1 - q_1^2}} \tag{18}$$

$$h_{q_3} = 1. \tag{19}$$

The HELMHOLTZ DIFFERENTIAL EQUATION is SEPARABLE.

Elliptic Exponential Function

The inverse of the ELLIPTIC LOGARITHM

$$\operatorname{eln}(x) \equiv \int_x^\infty \frac{dt}{\sqrt{t^3 + at^2 + bt}}.$$

It is doubly periodic in the COMPLEX PLANE.

Elliptic Fixed Point (Differential Equations)

A FIXED POINT for which the STABILITY MATRIX is purely IMAGINARY, $\lambda_\pm = \pm i\omega$ (for $\omega > 0$).

See also DIFFERENTIAL EQUATION, FIXED POINT, HYPERBOLIC FIXED POINT (DIFFERENTIAL EQUATIONS), PARABOLIC FIXED POINT, STABLE IMPROPER NODE, STABLE NODE, STABLE SPIRAL POINT, STABLE STAR, UNSTABLE IMPROPER NODE, UNSTABLE NODE, UNSTABLE SPIRAL POINT, UNSTABLE STAR

References

Elliptic Fixed Point (Map)

A FIXED POINT of a LINEAR TRANSFORMATION (MAP) for which the rescaled variables satisfy

$$(\delta - \alpha)^2 + 4\beta\gamma < 0.$$

See also HYPERBOLIC FIXED POINT (MAP), LINEAR TRANSFORMATION, PARABOLIC FIXED POINT

Elliptic Function

A DOUBLY PERIODIC FUNCTION with periods $2\omega_1$ and $2\omega_2$ such that

$$f(z + 2\omega_1) = f(z + 2\omega_2) = f(z), \tag{1}$$

which is ANALYTIC and has no singularities except for POLES in the finite part of the COMPLEX PLANE. The HALF-PERIOD RATIO $\tau \equiv \omega_2/\omega_1$ must not be purely real, because if it is, the function reduces to a singly periodic function if τ is rational, and a constant if τ is irrational (Jacobi 1835). ω_1 and ω_2 are labeled such that $\Im[\tau] \equiv \Im[\omega_2/\omega_1] > 0$, where $\Im[z]$ is the IMAGINARY PART.

A "cell" of an elliptic function is defined as a parallelogram region in the COMPLEX PLANE in which the function is not multi-valued. Properties obeyed by elliptic functions include

1. The number of POLES in a cell is finite.
2. The number of ROOTS in a cell is finite.
3. The sum of RESIDUES in any cell is 0.
4. LIOUVILLE'S ELLIPTIC FUNCTION THEOREM: An elliptic function with no POLES in a cell is a constant.
5. The number of zeros of $f(z) - c$ (the "order"rpar; equals the number of POLES of $f(z)$.
6. The simplest elliptic function has order two, since a function of order one would have a simple irreducible POLE, which would need to have a NONZERO residue. By property (3), this is impossible.
7. Elliptic functions with a single POLE of order 2 with RESIDUE 0 are called WEIERSTRASS ELLIPTIC FUNCTIONS. Elliptic functions with two simple POLES having residues a_0 and $-a_0$ are called JACOBI ELLIPTIC FUNCTIONS.
8. Any elliptic function is expressible in terms of either WEIERSTRASS ELLIPTIC FUNCTION or JACOBI ELLIPTIC FUNCTIONS.
9. The sum of the AFFIXES of ROOTS equals the sum of the AFFIXES of the POLES.
10. An algebraic relationship exists between any two elliptic functions with the same periods.

The elliptic functions are inversions of the ELLIPTIC INTEGRALS. The two standard forms of these functions are known as JACOBI ELLIPTIC FUNCTIONS and WEIERSTRASS ELLIPTIC FUNCTIONS. JACOBI ELLIPTIC FUNCTIONS arise as solutions to differential equations OF THE FORM

$$\frac{d^2x}{dt^2} = A + Bx + Cx^2 + Dx^3, \tag{2}$$

and WEIERSTRASS ELLIPTIC FUNCTIONS arise as solutions to differential equations OF THE FORM

$$\frac{d^2x}{dt^2} = A + Bx + Cx^2. \tag{3}$$

Elliptic Functional

COERCIVE FUNCTIONAL

Elliptic Geometry

A constant curvature NON-EUCLIDEAN GEOMETRY which replaces the PARALLEL POSTULATE with the statement "through any point in the plane, there exist no lines PARALLEL to a given line." Elliptic geometry is sometimes also called RIEMANNIAN GEOMETRY. It can be visualized as the surface of a SPHERE on which "lines" are taken as GREAT CIRCLES. In elliptic geometry, the sum of angles of a TRIANGLE is $> 180°$.

See also EUCLIDEAN GEOMETRY, HYPERBOLIC GEOMETRY, NON-EUCLIDEAN GEOMETRY

Elliptic Group Modulo p

$E(a, b)/p$ denotes the elliptic GROUP modulo p whose elements are 1 and ∞ together with the pairs of INTEGERS (x, y) with $0 \le x, y < p$ satisfying

$$y^2 \equiv x^3 + ax + b \pmod p \tag{1}$$

with a and b INTEGERS such that

$$4a^3 + 27b^2 \not\equiv 0 \pmod p. \tag{2}$$

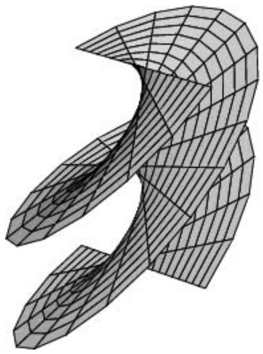
Given (x_1, y_1), define

$$(x_i, y_i) \equiv (x_1, y_1)^i \pmod p. \tag{3}$$

The ORDER h of $E(a, b)/p$ is given by

$$h = 1 + \sum_{x=1}^{p} \left[\left(\frac{x^3 + ax + b}{p} \right) + 1 \right], \tag{4}$$

where $x^3 + ax + b/p$ is the LEGENDRE SYMBOL, although this FORMULA quickly becomes impractical. However, it has been proven that



$$p + 1 - 2\sqrt{p} \le h(E(a, b)/p) \le p + 1 + 2\sqrt{p}. \tag{5}$$

Furthermore, for p a PRIME > 3 and INTEGER n in the above interval, there exists a and b such that

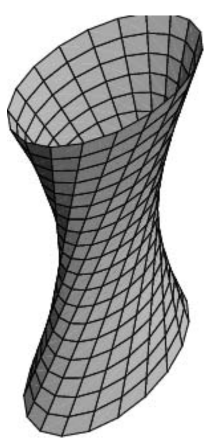
$$h(E(a, b)/p) = n, \tag{6}$$

and the orders of elliptic GROUPS mod p are nearly uniformly distributed in the interval.

Elliptic Helicoid

A generalization of the HELICOID to the PARAMETRIC EQUATIONS

$$x(u,\ v) = av \cos u$$



$$y(u,\ v) = bv \sin u$$

$$z(u,\ v) = cu.$$

See also HELICOID

Elliptic Hyperboloid

The elliptic hyperboloid is the generalization of the HYPERBOLOID to three distinct semimajor axes. The elliptic hyperboloid of one sheet is a RULED SURFACE and has Cartesian equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1, \tag{1}$$

and PARAMETRIC EQUATIONS

$$x(u,\ v) = a\sqrt{1+u^2} \cos v \tag{2}$$

$$y(u,\ v) = b\sqrt{1+u^2} \sin v \tag{3}$$

$$z(u,\ v) = cu \tag{4}$$

for $v \in [0,\ 2\pi)$, or

$$x(u,\ v) = a(\cos u \mp v \sin u) \tag{5}$$

$$y(u,\ v) = b(\sin u \pm v \cos u) \tag{6}$$

$$z(u,\ v) = \pm cv, \tag{7}$$

or

$$x(u,\ v) = a \cosh v \cos u \tag{8}$$

$$y(u,\ v) = b \cosh v \sin u \tag{9}$$

$$z(u,\ v) = c \sinh v. \tag{10}$$

The two-sheeted elliptic hyperboloid oriented along the z-AXIS has Cartesian equation

$$\frac{x^2}{a^2} + \frac{y^2}{a^2} - \frac{z^2}{c^2} = -1, \tag{11}$$

and PARAMETRIC EQUATIONS

$$x = a \sinh u \cos v \tag{12}$$

$$y = b \sinh u \sin v \tag{13}$$

$$z = c \pm \cosh u. \tag{14}$$

The two-sheeted elliptic hyperboloid oriented along the x-AXIS has Cartesian equation

$$\frac{x^2}{a^2} - \frac{y^2}{a^2} - \frac{z^2}{c^2} = 1 \tag{15}$$

and PARAMETRIC EQUATIONS

$$x = a \cosh u \cosh v \tag{16}$$

$$y = b \sinh u \cosh v \tag{17}$$

$$z = c \sinh v. \tag{18}$$

Elliptic Integral

An elliptic integral is an INTEGRAL OF THE FORM

$$\int \frac{A(x) + B(x)\sqrt{S(x)}}{A(x) + D(x)\sqrt{S(x)}}\, dx, \tag{1}$$

or

$$\int \frac{A(x)\, dx}{B(x)\sqrt{S(x)}}, \tag{2}$$

where $A(x)$, $B(x)$, $C(x)$, and $D(x)$ are POLYNOMIALS in x, and $S(x)$ is a POLYNOMIAL of degree 3 or 4. Stated more simply, an elliptic integral is an integral OF THE FORM

$$\int R(w,\ x)\,dx, \tag{3}$$

where $R(w,\ x)$ is a RATIONAL FUNCTION of x and w, w^2 is a function of x that is CUBIC or QUARTIC in x, $R(w,\ x)$ contains at least one ODD POWER of w, and w^2 has no repeated factors (Abramowitz and Stegun 1972, p. 589).

Elliptic integrals can be viewed as generalizations of the inverse TRIGONOMETRIC FUNCTIONS and provide solutions to a wider class of problems. For instance, while the ARC LENGTH of a CIRCLE is given as a simple function of the parameter, computing the ARC LENGTH of an ELLIPSE requires an elliptic integral. Similarly, the position of a pendulum is given by a TRIGONOMETRIC FUNCTION as a function of time for small angle oscillations, but the full solution for arbitrarily large displacements requires the use of elliptic integrals. Many other problems in electromagnetism and gravitation are solved by elliptic integrals.

A very useful class of functions known as ELLIPTIC FUNCTIONS is obtained by inverting elliptic integrals to obtain generalizations of the trigonometric functions. ELLIPTIC FUNCTIONS (among which the JACOBI ELLIPTIC FUNCTIONS and WEIERSTRASS ELLIPTIC FUNCTION are the two most common forms) provide a powerful tool for analyzing many deep problems in NUMBER THEORY, as well as other areas of mathematics.

All elliptic integrals can be written in terms of three "standard" types. To see this, write

$$R(w,\ x) \equiv \frac{P(w,\ x)}{Q(w,\ x)} = \frac{wP(w,\ x)Q(-w,\ x)}{wQ(w,\ x)Q(-w,\ x)}. \tag{4}$$

But since $w^2 = f(x)$,

$$Q(w,\ x)Q(-w,\ x) \equiv Q_1(w,\ x) = Q_1(-w,\ x), \tag{5}$$

then

$$\begin{aligned} wP(w,\ x)Q(-w,\ x) &= A + Bx + Cw + Dx^2 + Ewx \\ &\quad + Fw^2 + Gw^2x + Hw^3x \\ &= (A + Bx + Dx^2 + Fw^2 + Gw^2x) \\ &\quad + w(c + Ex + Hw^2x + \ldots) \\ &= P_1(x) + wP_2(x), \end{aligned} \tag{6}$$

so

$$R(w,\ x) = \frac{P_1(x) + wP_2(x)}{wQ_1(w)} = \frac{R_1(x)}{w} + R_2(x). \tag{7}$$

But any function $\int R_2(x)\,dx$ can be evaluated in terms of elementary functions, so the only portion that need be considered is

$$\frac{\int R_1(x)}{w}\,dx. \tag{8}$$

Now, any quartic can be expressed as S_1S_2 where

$$S_1 \equiv a_1x^2 + 2b_1x + c_1 \tag{9}$$

$$S_2 \equiv a_2x^2 + 2b_2x + c_2. \tag{10}$$

The COEFFICIENTS here are real, since pairs of COMPLEX ROOTS are COMPLEX CONJUGATES

$$\begin{aligned} &[x - (R + Ii)][x - (R - Ii)] \\ &\quad = x^2 + x(-R + Ii - R - Ii) + (R^2 - I^2 i) \\ &\quad = x^2 - 2Rx + (R^2 + I^2). \end{aligned} \tag{11}$$

If all four ROOTS are real, they must be arranged so as not to interleave (Whittaker and Watson 1990, p. 514). Now define a quantity λ such that $S_1 + \lambda S_2$

$$(a_1 - \lambda a_2)x^2 - (2b_1 - 2b_2\lambda)x + (c_1 - \lambda c_2) \tag{12}$$

is a SQUARE NUMBER and

$$2\sqrt{(a_1 - \lambda a_2)(c_1 - \lambda_2)} = 2(b_1 - b_2\lambda) \tag{13}$$

$$(a_1 - \lambda a_2)(c_1 - \lambda c_2) - (b_1 - \lambda b_2)^2 = 0. \tag{14}$$

Call the ROOTS of this equation λ_1 and λ_2, then

$$\begin{aligned} S_1 - \lambda_1 S_2 &= \left[\sqrt{(a_1 - \lambda_1 a_2)x} + \sqrt{c_1 - \lambda c_2}\right]^2 \\ &= (a_1 - \lambda_1 a_2)\left(x + \sqrt{\frac{c_1 - \lambda_1 c_2}{a_1 - \lambda_1 a_2}}\right) \\ &\equiv (a_1 - \lambda_1 a_2)(x - \alpha)^2 \end{aligned} \tag{15}$$

$$\begin{aligned} S_1 - \lambda_2 S_2 &= \left[\sqrt{(a_1 - \lambda_1 a_2)x} + \sqrt{c_1 - \lambda c_2}\right]^2 \\ &= (a_1 - \lambda_1 a_2)\left(x + \sqrt{\frac{c_1 - \lambda_2 c_2}{a_1 - \lambda_2 a_2}}\right) \\ &\equiv (a_1 - \lambda_2 a_2)(x - \beta)^2. \end{aligned} \tag{16}$$

Taking (15)-(16) and $\lambda_2(1) - \lambda_1(2)$ gives

$$\begin{aligned} S_2(\lambda_2 - \lambda_1) &= (a_1 - \lambda_1 a_2)(x - \alpha)^2 - (a_1 - \lambda_2 a_2) \\ &\quad \times (x - \beta)^2 \end{aligned} \tag{17}$$

$$\begin{aligned} S_1(\lambda_2 - \lambda_1) &= \lambda_2(a_1 - \lambda_1 a_2)(x - \alpha)^2 - \lambda_1(a_1 - \lambda_2 a_2) \\ &\quad \times (x - \beta^2). \end{aligned} \tag{18}$$

Solving gives

$$\begin{aligned} S_1 &= \frac{a_1 - \lambda_1 a_2}{\lambda_2 - \lambda_1}(x - \alpha)^2 - \frac{a_1 - \lambda_2 a_2}{\lambda_2 - \lambda_1}(x - \beta)^2 \\ &\equiv A_1(x - \alpha)^2 + B_1(x - \beta)^2 \end{aligned} \tag{19}$$

$$S_2 = \frac{\lambda_2(a_1 - \lambda_1 a_2)}{\lambda_2 - \lambda_1}(x-\alpha)^2 - \frac{\lambda_1(a_1 - \lambda_2 a_2)}{\lambda_2 - \lambda_1}(x-\beta)^2$$

$$\equiv A_2(x-\alpha)^2 + B_2(x-\beta)^2, \tag{20}$$

so we have

$$w^2 = S_1 S_2 = [A_1(x-\alpha)^2 + B_1(x-\beta)^2] \times [A^2(x-\alpha)^2 + B^2(x-\beta)^2]. \tag{21}$$

Now let

$$t \equiv \frac{x-\alpha}{x-\beta} \tag{22}$$

$$dy = [(x-\beta)^{-1} - (x-\alpha)(x-\beta)^{-2}]\, dx$$

$$= \frac{(x-\beta)-(x-\alpha)}{(x-\beta)^2}\, dx$$

$$= \frac{\alpha-\beta}{(x-\beta)^2}\, dx, \tag{23}$$

so

$$w^2 = (x-\beta)^4 \left[A_1 \left(\frac{x-\alpha}{x-\beta}\right)^2 + B_1\right] \left[A_2 \left(\frac{x-\alpha}{x-\beta}\right) + B_2\right]$$

$$= (x-\beta)^4 (A_1 t^2 + B_1)(A_2 t^2 + B_2), \tag{24}$$

and

$$w = (x-\beta)^2 \sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)} \tag{25}$$

$$\frac{dx}{w} = \left[\frac{(x-\beta)^2}{\alpha-\beta}\, dt\right] \frac{1}{(x-\beta)^2 \sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}}$$

$$= \frac{dt}{(\alpha-\beta)\sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}}. \tag{26}$$

Now let

$$R_3(t) \equiv \frac{R_1(x)}{\alpha-\beta}, \tag{27}$$

so

$$\int \frac{R_1(x)\, dx}{w} = \int \frac{R_3(t)\, dt}{\sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}}. \tag{28}$$

Rewriting the EVEN and ODD parts

$$R_3(t) + R_3(-t) \equiv 2R_4(t^2) \tag{29}$$

$$R_3(t) - R_3(-t) \equiv 2tR_5(t^2), \tag{30}$$

gives

$$R_3(t) \equiv \tfrac{1}{2}(R_{\rm even} - R_{\rm odd}) = R_4(t^2) + tR_5(t^2), \tag{31}$$

so we have

$$\int \frac{R_1(x)\, dx}{w} = \int \frac{R_4(t^2)\, dt}{\sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}} + \int \frac{R_5(t^2) t\, dt}{\sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}}. \tag{32}$$

Letting

$$u \equiv t^2 \tag{33}$$

$$du = 2t\, dt \tag{34}$$

reduces the second integral to

$$\frac{1}{2}\int \frac{R_5(u)\, du}{\sqrt{(A_1 u + B_1)(A_2 u + B_2)}}, \tag{35}$$

which can be evaluated using elementary functions. The first integral can then be reduced by INTEGRATION BY PARTS to one of the three Legendre elliptic integrals (also called Legendre-Jacobi ELLIPTIC INTEGRALS), known as incomplete elliptic integrals of the first, second, and third kind, denoted $F(\phi, k)$, $E(\phi, k)$, and $\prod(n; \phi, k)$, respectively (von Kármán and Biot 1940, Whittaker and Watson 1990, p. 515). If $\phi = \pi/2$, then the integrals are called complete elliptic integrals and are denoted $K(k)$, $E(k)$, $\prod(n; k)$.

Incomplete elliptic integrals are denoted using a MODULUS k, PARAMETER $m \equiv k^2$, or MODULAR ANGLE $\alpha \equiv \sin^{-1} k$. An elliptic integral is written $I(\phi|m)$ when the PARAMETER is used, $I(\phi, k)$ when the MODULUS is used, and $I(\phi\backslash\alpha)$ when the MODULAR ANGLE is used. Complete elliptic integrals are defined when $\phi = \pi/2$ and can be expressed using the expansion

$$(1 - k^2 \sin^2\theta)^{-1/2} = \sum_{n=0}^{\infty} \frac{(2n-1)!!}{(2n)!!} k^{2n} \sin^{2n}\theta. \tag{36}$$

An elliptic integral in standard form

$$\int_a^x \frac{dx}{\sqrt{f(x)}}, \tag{37}$$

where

$$f(x) = a_4 x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0, \tag{38}$$

can be computed analytically (Whittaker and Watson 1990, p. 453) in terms of the WEIERSTRASS ELLIPTIC FUNCTION with invariants

$$g_2 = a_0 a_4 - 4a_1 a_3 + 3a_2^2 \tag{39}$$

$$g_3 = a_0 a_2 a_4 - 2a_1 a_2 a_3 - a_4 a_1^2 - a_3^2 a_0. \tag{40}$$

If $a \equiv x_0$ is a root of $f(x) = 0$, then the solution is

$$x = x_0 + \tfrac{1}{4} f'(x_0)[\wp(z; g_2, g_3) - \tfrac{1}{24} f''(x_0)]^{-1}. \tag{41}$$

For an arbitrary lower bound,

$$x=a$$
$$+\frac{\sqrt{f(a)}\wp'(z)\frac{1}{2}f'(a)[\wp(z)-\frac{1}{24}f''(a)]+\frac{1}{24}f(a)f'''(a)}{2[\wp(z)-\frac{1}{24}f''(a)]^2-\frac{1}{48}f(a)f^{(iv)}(a)}, \quad (42)$$

where $\wp(z)\equiv\wp(z;\, g_2,\, g_3)$ is a WEIERSTRASS ELLIPTIC FUNCTION (Whittaker and Watson 1990, p. 454).

A generalized elliptic integral can be defined by the function

$$T(a,\, b)\equiv\frac{2}{\pi}\int_0^{\pi/2}\frac{d\theta}{\sqrt{a^2\cos^2\theta+b^2\sin^2\theta}} \quad (43)$$

$$=\frac{2}{\pi}\int_0^{\pi/2}\frac{d\theta}{\cos\theta\sqrt{a^2+b^2\tan^2\theta}} \quad (44)$$

(Borwein and Borwein 1987). Now let

$$t\equiv b\tan\theta \quad (45)$$

$$dt=b\sec^2\theta\, d\theta. \quad (46)$$

But

$$\sec\theta=\sqrt{1+\tan^2\theta}, \quad (47)$$

so

$$dt=\frac{b}{\cos\theta}\sec\theta\, d\theta=\frac{b}{\cos\theta}\sqrt{1+\tan^2\theta}\, d\theta$$

$$=\frac{b}{\cos\theta}\sqrt{1+\left(\frac{t}{b}\right)^2}\, d\theta$$

$$=\frac{d\theta}{\cos\theta}\sqrt{b^2+t^2}, \quad (48)$$

and

$$\frac{d\theta}{\cos\theta}=\frac{dt}{\sqrt{b^2+t^2}}, \quad (49)$$

and the equation becomes

$$T(a,\, b)=\frac{2}{\pi}\int_0^{\infty}\frac{dt}{\sqrt{(a^2+t^2)(b^2+t^2)}}$$

$$=\frac{1}{\pi}\int_{-\infty}^{\infty}\frac{dt}{\sqrt{(a^2+t^2)(b^2+t^2)}}. \quad (50)$$

Now we make the further substitution $u\equiv\frac{1}{2}(t-ab/t)$. The differential becomes

$$du=\tfrac{1}{2}(1+ab/t^2)\, dt, \quad (51)$$

but $2u=t-ab/t$, so

$$2u/t=1-ab/t^2 \quad (52)$$

$$ab/t^2=1-2u/t \quad (53)$$

and

$$1+ab/t^2=2-2u/t=2(1-u/t). \quad (54)$$

However, the left side is always positive, so

$$1+ab/t^2=2-2u/t=2|1-u/t| \quad (55)$$

and the differential is

$$dt=\frac{du}{\left|1-\frac{u}{t}\right|}. \quad (56)$$

We need to take some care with the limits of integration. Write (50) as

$$\int_{-\infty}^{\infty}f(t)\, dt=\int_{-\infty}^{0-}f(t)\, dt+\int_{0+}^{\infty}f(t)\, dt. \quad (57)$$

Now change the limits to those appropriate for the u integration

$$\int_{-\infty}^{\infty}g(u)\, du+\int_{-\infty}^{\infty}g(u)\, du=2\int_{-\infty}^{\infty}g(u)\, du, \quad (58)$$

so we have picked up a factor of 2 which must be included. Using this fact and plugging (56) in (50) therefore gives

$$T(a,\, b)=\frac{2}{\pi}\int_{-\infty}^{\infty}\frac{du}{\left|1-\frac{u}{t}\right|\sqrt{a^2b^2+(a^2+b^2)t^2+t^4}}. \quad (59)$$

Now note that

$$u^2=\frac{t^4-2abt^2+a^2b^2}{4t^2} \quad (60)$$

$$4u^2t^2=t^4-2abt^2+a^2b^2 \quad (61)$$

$$a^2b^2+t^4=4u^2t^2+2abt^2. \quad (62)$$

Plug (62) into (59) to obtain

$$T(a,\, b)=\frac{2}{\pi}\int_{-\infty}^{\infty}\frac{du}{\left|1-\frac{u}{t}\right|\sqrt{4u^2t^2+2abt^2+(a^2+b^2)t^2}}$$

$$=\frac{2}{\pi}\int_{-\infty}^{\infty}\frac{du}{|t-u|\sqrt{4u^2+(a+b)^2}}. \quad (63)$$

But

$$2ut=t^2-ab \quad (64)$$

$$t^2-2ut-ab=0 \quad (65)$$

$$t=\tfrac{1}{2}(2u\pm\sqrt{4u^2+4ab})=u\pm\sqrt{u^2+ab}, \quad (66)$$

so

$$t-u=\pm\sqrt{u^2+ab}, \quad (67)$$

and (63) becomes

$$T(a, b) = \frac{2}{\pi}\int_{-\infty}^{\infty} \frac{du}{\sqrt{[4u^2 + (a+b)^2] + (u^2 + ab)}}$$

$$= \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{du}{\sqrt{\left[u^2 + \left(\frac{a+b}{2}\right)^2\right](u^2 + ab)}}. \tag{68}$$

We have therefore demonstrated that

$$T(a, b) = T(\tfrac{1}{2}(a+b), \sqrt{ab}). \tag{69}$$

We can thus iterate

$$a_{i+1} = \tfrac{1}{2}(a_i + b_i) \tag{70}$$

$$b_{i+1} = \sqrt{a_i b_i}, \tag{71}$$

as many times as we wish, without changing the value of the integral. But this iteration is the same as and therefore converges to the ARITHMETIC-GEOMETRIC MEAN, so the iteration terminates at $a_i = b_i = M(a_0, b_0)$, and we have

$$T(a_0, b_0) = T(M(a_0, b_0), M(a_0, b_0))$$

$$= \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{dt}{M^2(a_0, b_0) + t^2}$$

$$= \frac{1}{\pi M(a_0, b_0)}\left[\tan^{-1}\left(\frac{t}{M(a_0, b_0)}\right)\right]_{-\infty}^{\infty}$$

$$= \frac{1}{\pi M(a_0, b_0)}\left[\frac{\pi}{2} - \left(-\frac{\pi}{2}\right)\right]$$

$$= \frac{1}{M(a_0, b_0)}. \tag{72}$$

Complete elliptic integrals arise in finding the arc length of an ELLIPSE and the period of a pendulum. They also arise in a natural way from the theory of THETA FUNCTIONS. Complete elliptic integrals can be computed using a procedure involving the ARITHMETIC-GEOMETRIC MEAN. Note that

$$T(a, b) \equiv \frac{2}{\pi}\int_0^{\pi/2} \frac{d\theta}{\sqrt{a^2 \cos^2\theta + b^2 \sin^2\theta}}$$

$$= \frac{2}{\pi}\int_0^{\pi/2} \frac{d\theta}{a\sqrt{\cos^2\theta + \left(\frac{b}{a}\right)^2 \sin^2\theta}}$$

$$= \frac{2}{a\pi}\int_0^{\pi/2} \frac{d\theta}{\sqrt{1 - \left(1 - \frac{b^2}{a^2}\right)^2 \sin^2\theta}}. \tag{73}$$

So we have

$$T(a, b) = \frac{2}{a\pi}K\left(1 - \frac{b^2}{a^2}\right) = \frac{1}{M(a, b)}, \tag{74}$$

where $K(k)$ is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND. We are free to let $a \equiv a_0 \equiv 1$ and $b \equiv b_0 \equiv k'$, so

$$\frac{2}{\pi}K(\sqrt{1-k'^2}) = \frac{2}{\pi}K(k) = \frac{1}{M(1, k')}, \tag{75}$$

since $k \equiv \sqrt{1-k'^2}$, so

$$K(k) = \frac{\pi}{2M(1, k')}. \tag{76}$$

But the ARITHMETIC-GEOMETRIC MEAN is defined by

$$a_i = \tfrac{1}{2}(a_{i-1} + b_{i-1}) \tag{77}$$

$$b_i = \sqrt{a_{i-1} + b_{i-1}} \tag{78}$$

$$c_i = \begin{cases} \tfrac{1}{2}(a_{i-1} - b_{i-1}) & i > 0 \\ \sqrt{a_0^2 - b_0^2} & i = 0 \end{cases}, \tag{79}$$

where

$$c_{n-1} = \tfrac{1}{2}a_n - b_n = \frac{c_n^2}{4a_{n+1}} \leq \frac{c_n^2}{4M(a_0, b_0)}, \tag{80}$$

so we have

$$K(k) = \frac{\pi}{2a_N}, \tag{81}$$

where a_N is the value to which a_n converges. Similarly, taking instead $a_0' = 1$ and $b_0' = k$ gives

$$K'(k) = \frac{\pi}{2a_N'}. \tag{82}$$

Borwein and Borwein (1987) also show that defining

$$U(a, b) \equiv \frac{\pi}{2}\int_0^{\pi/2} \sqrt{a^2 \cos^2 + b^2 \sin^2\theta}\, d\theta$$

$$= aE'\left(\frac{b}{a}\right) \tag{83}$$

leads to

$$2U(a_{n+1}, b_{n+1}) - U(a_n, b_n) = a_n b_n T(a_n, b_n), \tag{84}$$

so

$$\frac{K(k) - E(k)}{K(k)} = \tfrac{1}{2}(c_0^2 + 2c_1^2 + 2^2 c_2^2 + \ldots + 2^n c_n^2) \tag{85}$$

for $a_0 \equiv 1$ and $b_0 \equiv k'$, and

$$\frac{K'(k) - E'(k)}{K'(k)} = \tfrac{1}{2}(c_0'^2 + 2c_1'^2 + 2^2 c_2'^2 + \ldots + 2^n c_n'^2). \quad (86)$$

The elliptic integrals satisfy a large number of identities. The complementary functions and moduli are defined by

$$K'(k) \equiv K(\sqrt{1-k^2}) = K(k'). \quad (87)$$

Use the identity of generalized elliptic integrals

$$T(a,\ b) = T(\tfrac{1}{2}(a+b),\ \sqrt{ab}) \quad (88)$$

to write

$$\frac{1}{a}K\left(\sqrt{1-\frac{b^2}{a^2}}\right) = \frac{2}{a+b}K\left(\sqrt{1-\frac{4ab}{(a+b)^2}}\right)$$

$$= \frac{2}{a+b}K\left(\sqrt{\frac{a^2+b^2-2ab}{(a+b)^2}}\right)$$

$$= \frac{2}{a+b}K\left(\frac{a-b}{a+b}\right) \quad (89)$$

$$K\left(\sqrt{1-\frac{b^2}{a^2}}\right) = \frac{2}{1+\frac{b}{a}}\ K\left(\frac{1-\frac{b}{a}}{1+\frac{b}{a}}\right). \quad (90)$$

Define

$$k' \equiv \frac{b}{a}, \quad (91)$$

and use

$$k \equiv \sqrt{1-k'^2}, \quad (92)$$

so

$$K(k) = \frac{2}{1+k'}K\left(\frac{1-k'}{1+k'}\right). \quad (93)$$

Now letting $l \equiv (1-k')/(1+k')$ gives

$$l(1+k') = 1-k' \Rightarrow k'(l+1) = 1-l \quad (94)$$

$$k' = \frac{1-l}{1+l} \quad (95)$$

$$k = \sqrt{1-k'^2} = \sqrt{1-\left(\frac{1-l}{1+l}\right)^2}$$

$$= \sqrt{\frac{(1+l)^2-(1-l)^2}{(1+l)^2}} = \frac{2\sqrt{l}}{1+l}, \quad (96)$$

and

$$\tfrac{1}{2}(1+k') = \frac{1}{2}\left(1+\frac{1-l}{1+l}\right) = \frac{1}{2}\left[\frac{(1+l)+(1-l)}{1+l}\right]$$

$$= \frac{1}{1+l}. \quad (97)$$

Writing k instead of l,

$$k(k) = \frac{1}{k+1}K\left(\frac{2\sqrt{k}}{1+k}\right). \quad (98)$$

Similarly, from Borwein and Borwein (1987),

$$E(k) = \frac{1+k}{2}\ E\left(\frac{2\sqrt{k}}{1+k}\right) + \frac{k'^2}{2}\ K(k) \quad (99)$$

$$E(k) = (1+k')E\left(\frac{1-k'}{1+k'}\right) - k'K(k). \quad (100)$$

Expressions in terms of the complementary function can be derived from interchanging the moduli and their complements in (93), (98), (99), and (100).

$$K'(k) = K(k') = \frac{2}{1+k}K\left(\frac{1-k}{1+k}\right)$$

$$= \frac{2}{1+k}K'\left(\sqrt{1-\left(\frac{1-k}{1+k}\right)^2}\right)$$

$$= \frac{2}{1+k}K'\left(\frac{2\sqrt{k}}{1+k}\right) \quad (101)$$

$$K'(k) = \frac{1}{1+k'}\ K\left(\frac{2\sqrt{k'}}{1+k'}\right)$$

$$= \frac{1}{1+k'}\ K'\left(\frac{1-k'}{1+k'}\right), \quad (102)$$

and

$$E'(k) = (1+k)E'\left(\frac{2\sqrt{k}}{1+k}\right) - kK'(k) \quad (103)$$

$$E'(k) = \left(\frac{1+k'}{2}\right)E'\left(\frac{1-k'}{1+k'}\right) + \frac{k^2}{2}K'(k). \quad (104)$$

Taking the ratios

$$\frac{K'(k)}{K(k)} = 2\frac{K'\left(\frac{2\sqrt{k}}{1+k}\right)}{K\left(\frac{2\sqrt{k}}{1+k}\right)} = \frac{1}{2}\ \frac{K'\left(\frac{1-k'}{1+k'}\right)}{K\left(\frac{1-k'}{1+k'}\right)} \quad (105)$$

gives the MODULAR EQUATION of degree 2. It is also true that

$$K(x) = \frac{4}{(1+\sqrt{x'})^2} K\left(\left[\frac{1-\sqrt{1-x^4}}{1+\sqrt{1-x^4}}\right]^2\right). \tag{106}$$

Elliptic Integral of the First Kind

Let the MODULUS k satisfy $0 < k^2 < 1$, and the AMPLITUDE be given by $\phi = \operatorname{am} u$. The incomplete elliptic integral of the first kind is then defined as

$$u = F(\phi, k) = \int_0^\phi \frac{d\theta}{\sqrt{1-k^2\sin^2\theta}}. \tag{1}$$

Let

$$t \equiv \sin\theta \tag{2}$$

$$dt = \cos\theta\, d\theta = \sqrt{1-t^2}\, d\theta, \tag{3}$$

then (1) can be written as

$$F(\phi, k) = \int_0^{\sin\phi} \frac{1}{\sqrt{1-k^2t^2}} \frac{dt}{\sqrt{1-t^2}} = \int_0^{\sin\phi} \frac{dt}{\sqrt{1-k^2t^2}\sqrt{1-t^2}}. \tag{4}$$

Let

$$v \equiv \tan\theta \tag{5}$$

$$dv \equiv \sec^2\theta\, d\theta = (1+v^2)\, d\theta, \tag{6}$$

then the integral can also be written as

$$F(\phi, k) = \int_0^{\tan\phi} \frac{1}{\sqrt{1-k^2\frac{v^2}{1+u^2}}} \frac{du}{1+v^2} = \int_0^{\tan\phi} \frac{dv}{\sqrt{1+v^2}\sqrt{(1+v^2)-k^2v^2}} \tag{7}$$

$$= \int_0^{\tan\phi} \frac{dv}{\sqrt{(1+v^2)(1+k'v^2)}}, \tag{8}$$

where $k'^2 \equiv 1-k^2$ is the complementary MODULUS. The elliptic integral of the first kind is implemented in *Mathematica* as `EllipticK`[*phi*, *m*] (*note the use of the parameter* $m = k^2$ *instead of the modulus* k).

The inverse function of $F(\phi, k)$ is given by the AMPLITUDE

$$F^{-1}(u, k) = \phi = \operatorname{am}(u, k) = \operatorname{am} u. \tag{9}$$

The integral

$$I = \frac{1}{\sqrt{2}} \int_0^{\theta_0} \frac{d\theta}{\sqrt{\cos\theta - \cos\theta_0}}, \tag{10}$$

which arises in computing the period of a pendulum, is also an elliptic integral of the first kind. Use

$$\cos\theta = 1 - 2\sin^2(\tfrac{1}{2}\theta) \tag{11}$$

$$\sin(\tfrac{1}{2}\theta) = \sqrt{\frac{1-\cos\theta}{2}} \tag{12}$$

to write

$$\sqrt{\cos\theta - \cos\theta_0} = \sqrt{1-2\sin^2(\tfrac{1}{2}\theta) - \cos\theta_0} = \sqrt{1-\cos\theta_0}\sqrt{1-\frac{2}{1-\cos\theta_0}\sin^2(\tfrac{1}{2}\theta)}$$

$$= \sqrt{2}\sin(\tfrac{1}{2}\theta_0)\sqrt{1-\csc^2(\tfrac{1}{2}\theta_0)\sin^2(\tfrac{1}{2}\theta)}, \tag{13}$$

so

$$I = \frac{1}{2}\int_0^{\theta_0} \frac{d\theta}{\sin(\tfrac{1}{2}\theta_0)\sqrt{1-\csc^2(\tfrac{1}{2}\theta_0)\sin^2(\tfrac{1}{2}\theta)}}. \quad (14)$$

Now let

$$\sin(\tfrac{1}{2}\theta) = \sin(\tfrac{1}{2}\theta_0)\sin\phi, \quad (15)$$

so the angle θ is transformed to

$$\phi = \sin^{-1}\left[\frac{\sin(\tfrac{1}{2}\theta)}{\sin(\tfrac{1}{2}\theta_0)}\right], \quad (16)$$

which ranges from 0 to $\pi/2$ as θ varies from 0 to θ_0. Taking the differential gives

$$\tfrac{1}{2}\cos(\tfrac{1}{2}\theta)\,d\theta = \sin(\tfrac{1}{2}\theta_0)\cos\phi\,d\phi, \quad (17)$$

or

$$\tfrac{1}{2}\sqrt{1-\sin^2(\tfrac{1}{2}\theta_0)\sin^2\phi}\,d\theta = \sin(\tfrac{1}{2}\theta_0)\cos\phi\,d\phi. \quad (18)$$

Plugging this in gives

$$I = \int_0^{\pi/2} \frac{1}{\sqrt{1-\sin^2(\tfrac{1}{2}\theta_0)\sin^2\phi}}\,\frac{\sin(\tfrac{1}{2}\theta_0)\cos\phi\,d\phi}{\sin(\tfrac{1}{2}\theta_0)\sqrt{1-\sin^2\phi}}$$

$$= \int_0^{\pi/2} \frac{d\phi}{\sqrt{1-\sin^2(\tfrac{1}{2}\theta_0)\sin^2\phi}} = K(\sin(\tfrac{1}{2}\theta_0)), \quad (19)$$

so

$$I = \frac{1}{\sqrt{2}}\int_0^{\theta_0} \frac{d\theta}{\sqrt{\cos\theta - \cos\theta_0}} = K(\sin(\tfrac{1}{2}\theta_0)). \quad (20)$$

Making the slightly different substitution $\phi = \theta/2$, so $d\theta = 2\,d\phi$ leads to an equivalent, but more complicated expression involving an *incomplete* elliptic integral of the first kind,

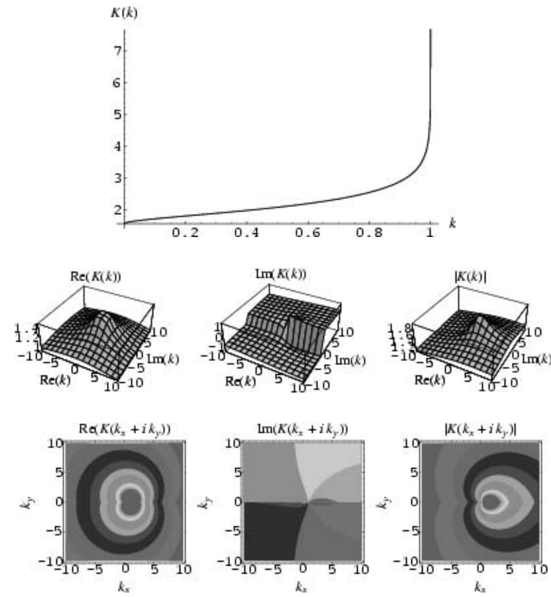
$$I = 2\frac{1}{\sqrt{2}}\frac{1}{\sqrt{2}}\csc(\tfrac{1}{2}\theta_0)\int_0^{\theta_0} \frac{d\theta}{\sqrt{1-\csc^2(\tfrac{1}{2}\theta_0)\sin^2\phi}}$$

$$= \csc(\tfrac{1}{2}\theta_0)F(\tfrac{1}{2}\theta_0,\ \csc(\tfrac{1}{2}\theta_0)). \quad (21)$$

Therefore, we have proven the identity

$$\csc x F(x,\ \csc x) = K(\sin x). \quad (22)$$

The elliptic integral of the first kind satisfies



$$F(-\phi,\ k) = -F(\phi,\ k). \quad (23)$$

Special values of $F(\phi,\ k)$ include

$$F(0,\ k) = 0 \quad (24)$$

$$F(\tfrac{1}{2}\pi,\ k) = K(k), \quad (25)$$

where $K(k)$ is known as the complete elliptic integral of the first kind.

The complete elliptic integral of the first kind, illustrated above as a function of $m = k^2$, is defined by

$$K(k) \equiv F(\tfrac{1}{2}\pi,\ k) \quad (26)$$

$$= \sum_{n=0}^{\infty} \frac{(2n-1)!!}{(2n)!!} k^{2n} \int_0^{2\pi} \sin^{2n}\theta\,d\theta \quad (27)$$

$$= \tfrac{1}{2}\pi\vartheta_3^2(q) \quad (28)$$

$$= \sum_{n=0}^{\infty} \frac{(2n-1)!!}{(2n)!!} k^{2n} \frac{\pi}{2}\frac{(2n-1)!!}{(2n)!!}$$

$$= \frac{\pi}{2}\sum_{n=0}^{\infty}\left[\frac{(2n-1)!!}{(2n)!!}\right]^2 k^{2n} \quad (29)$$

$$= \tfrac{1}{2}\pi\ {}_2F_1(\tfrac{1}{2},\ \tfrac{1}{2};\ 1;\ k^2) \quad (30)$$

$$= \frac{\pi}{2\sqrt{1-k^2}} P_{-1/2}\left(\frac{1+k^2}{1-k^2}\right), \quad (31)$$

where

$$q = e^{-\pi K'(k)/K(k)} \quad (32)$$

is the NOME (for $|q| < 1$), ${}_2F_1(a,\ b;\ c;\ x)$ is the HYPERGEOMETRIC FUNCTION, and $P_n(x)$ is a LEGENDRE POLYNOMIAL. $K(k)$ satisfies the LEGENDRE RELATION

$$E(k)K'(k) + E'(k)K(k) - K(k)K'(k) = \tfrac{1}{2}\pi, \quad (33)$$

where $K(k)$ and $E(k)$ are complete elliptic integrals of the first and SECOND KINDS, respectively, and $K'(k)$ and $E'(k)$ are the complementary integrals. The modulus k is often suppressed for conciseness, so that $K(k)$ and $E(k)$ are often simply written K and E, respectively.

The DERIVATIVE of $K(k)$ is

$$\frac{dK}{dk} \equiv \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-k'^2t^2)}} = \frac{E(k)}{k(1-k^2)} - \frac{K(k)}{k} \quad (34)$$

and $K(k)$ satisfies the differential equation

$$\frac{d}{dk}\left(kk'^2 \frac{dK}{dk}\right) = kK(k), \quad (35)$$

so

$$E = k(1-k^2)\left(\frac{dK}{dk} + \frac{K(k)}{k}\right) \quad (36)$$

$$= (1-k^2)\left(k\frac{dK}{dk} + K(k)\right) \quad (37)$$

(Whittaker and Watson 1990, pp. 499 and 521). Besides $y = K(k)$, the other solution to the differential equation

$$\frac{d}{dk}\left[k(1-k^2)\frac{dy}{dk}\right] - ky = 0 \quad (38)$$

(Zwillinger 1997, p. 122; Gradshteyn and Ryzhik 2000, p. 907) is MEIJER'S G-FUNCTION

$$y = G_{2,\,2}^{2,\,0}\left(k^2 \middle| \begin{matrix} \frac{1}{2}, \frac{1}{2} \\ 0,\ 0 \end{matrix}\right). \quad (39)$$

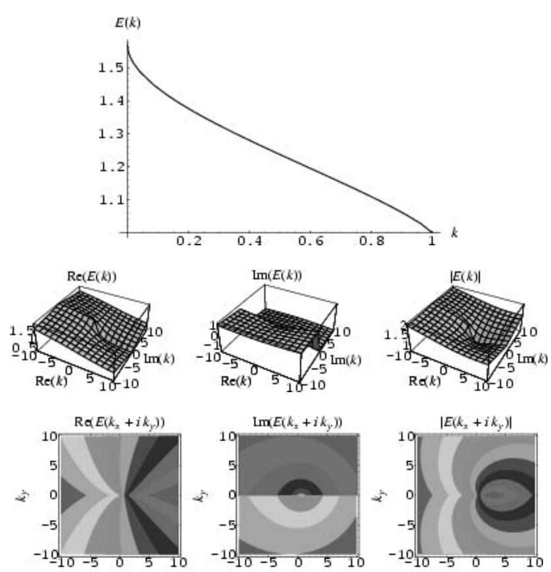
Elliptic Integral of the Second Kind

Let the MODULUS k satisfy $0 < k^2 < 1$. (This may also be written in terms of the PARAMETER $m \equiv k^2$ or MODULAR ANGLE $\alpha \equiv \sin^{-1} k$.) The incomplete elliptic integral of the second kind is then defined as

$$E(\phi,\ k) \equiv \int_0^{\phi} \sqrt{1-k^2\sin^2\theta}\, d\theta. \quad (1)$$

The elliptic integral of the second kind is implemented in *Mathematica* as `EllipticE[`*phi*, *m*`]` (*note the use of the parameter* $m = k^2$ *instead of the modulus* k).

To place the elliptic integral of the second kind in a slightly different form, let



$$t \equiv \sin\theta \quad (2)$$

$$dt = \cos\theta\, d\theta = \sqrt{1-t^2}\, d\theta, \quad (3)$$

so the elliptic integral can also be written as

$$E(\phi,\ k) = \int_0^{\sin\phi} \sqrt{1-k^2t^2}\, \frac{dt}{\sqrt{1-t^2}}$$

$$= \int_0^{\sin\phi} \sqrt{\frac{1-k^2t^2}{1-t^2}}\, dt. \quad (4)$$

The complete elliptic integral of the second kind, illustrated above as a function of the PARAMETER m, is defined by

$$E(k) \equiv E(\tfrac{1}{2}\pi,\ k) \quad (5)$$

$$= \frac{\pi}{2}\left\{1 - \sum_{n=1}^{\infty}\left[\frac{(2n-1)!!}{(2n)!!}\right]^2 \frac{k^{2n}}{2n-1}\right\} \quad (6)$$

$$= \tfrac{1}{2}\pi\ {}_2F_1(-\tfrac{1}{2},\ \tfrac{1}{2};\ 1;\ k^2) \quad (7)$$

$$= \int_0^K \mathrm{dn}^2\, u\, du, \quad (8)$$

where ${}_2F_1(a,\ b;\ c;\ x)$ is the HYPERGEOMETRIC FUNCTION and $\mathrm{dn}\, u$ is a JACOBI ELLIPTIC FUNCTION. The complete elliptic integral of the second kind satisfies the LEGENDRE RELATION

$$E(k)K'(k) + E'(k)K(k) - K(k)K'(k) = \tfrac{1}{2}\pi, \quad (9)$$

where $K(k)$ and $E(k)$ are complete ELLIPTIC INTEGRALS OF THE FIRST and second kinds, respectively, and $K'(k)$ and $E'(k)$ are the complementary integrals. The DERIVATIVE is

$$\frac{dE}{dk} = \frac{E(k) - K(k)}{k} \quad (10)$$

(Whittaker and Watson 1990, p. 521). Besides $y = E(k)$, the other solution to the differential equation

$$k'^2 \frac{d}{dk}\left(k \frac{dy}{dk}\right) + ky = 0 \quad (11)$$

(Zwillinger 1997, p. 122; Gradshteyn and Ryzhik 2000, p. 907) is MEIJER'S G-FUNCTION

$$y = G_{2,\ 2}^{2,\ 0}\left(k^2 \middle| \begin{matrix} \frac{1}{2},\ \frac{3}{2} \\ 0,\ 0 \end{matrix}\right). \quad (12)$$

If k_r is a singular value (i.e.,

$$k_r = \lambda^*(r), \quad (13)$$

where λ^* is the ELLIPTIC LAMBDA FUNCTION), and $K(k_r)$ and the ELLIPTIC ALPHA FUNCTION $\alpha(r)$ are also known, then

$$E(k) = \frac{K(k)}{\sqrt{r}}\left[\frac{\pi}{3[K(k)]^2} - \alpha(r)\right] + K(k). \quad (14)$$

A generalization replacing $\sin\theta$ with $\sinh\theta$ in (1) gives

$$-iE(i\phi,\ -k) = \int_0^{\phi} \sqrt{1 - k^2 \sinh^2\theta}\, d\theta. \quad (15)$$

Elliptic Integral of the Third Kind

Let $0 < k^2 < 1$. The incomplete elliptic integral of the third kind is then defined as

$$\Pi(n;\ \phi,\ k) = \int_0^{\phi} \frac{d\theta}{(1 - n\sin^2\theta)\sqrt{1 - k^2\sin^2\theta}} \quad (1)$$

$$= \int_0^{\sin\phi} \frac{dt}{(1 - nt^2)\sqrt{(1 - t^2)(1 - k^2t^2)}}, \quad (2)$$

where n is a constant known as the CHARACTERISTIC.

The complete elliptic integral of the third kind

$$\Pi(n|m) = \Pi(n;\ \tfrac{1}{2}\pi|m) \tag{3}$$

is illustrated above.

Elliptic Integral Singular Value

When the modulus k has a singular value, the complete elliptic integrals may be computed in analytic form in terms of gamma functions. Abel (quoted in Whittaker and Watson 1990, p. 525) proved that whenever

$$\frac{K'(k)}{K(k)} = \frac{a + b\sqrt{n}}{c + d\sqrt{n}}, \tag{1}$$

where a, b, c, d, and n are integers, $K(k)$ is a complete elliptic integral of the first kind, and $K'(k) \equiv K(\sqrt{1-k^2})$ is the complementary complete elliptic integral of the first kind, then the modulus k is the root of an algebraic equation with integer coefficients.

A modulus k_r such that

$$\frac{K'(k_r)}{K(k_r)} = \sqrt{r}, \tag{2}$$

is called a singular value of the elliptic integral. The elliptic lambda function $\lambda^*(r)$ gives the value of k_r. Selberg and Chowla (1967) showed that $K(\lambda^*(r))$ and $E(\lambda^*(r))$ are expressible in terms of a finite number of gamma functions. The complete elliptic integrals of the second kind $e(k_r)$ and $e'(k_r)$ can be expressed in terms of $k(k_r)$ and $k'(k_r)$ with the aid of the elliptic alpha function $\alpha(r)$.

The following table gives the values of $k(k_r)$ for small integral r in terms of gamma functions $\Gamma(z)$.

$$K(k_1) = \frac{\Gamma^2(\frac{1}{4})}{4\sqrt{\pi}}$$

$$K(k_2) = \frac{\sqrt{\sqrt{2}+1}\,\Gamma(\frac{1}{8})\Gamma(\frac{3}{8})}{2^{13/4}\sqrt{\pi}}$$

$$K(k_3) = \frac{3^{1/4}\Gamma^3(\frac{1}{3})}{2^{7/3}\pi}$$

$$K(k_4) = \frac{(\sqrt{2}+1)\Gamma^2(\frac{1}{4})}{2^{7/2}\sqrt{\pi}}$$

$$K(k_5) = (\sqrt{5}+2)^{1/4}\sqrt{\frac{\Gamma(\frac{1}{20})\Gamma(\frac{3}{20})\Gamma(\frac{7}{20})\Gamma(\frac{9}{20})}{160\pi}}$$

$$K(k_6) = \sqrt{(\sqrt{2}-1)(\sqrt{3}+\sqrt{2})(2+\sqrt{3})} \times \sqrt{\frac{\Gamma(\frac{1}{24})\Gamma(\frac{5}{24})\Gamma(\frac{7}{24})\Gamma(\frac{11}{24})}{384\pi}}$$

$$K(k_7) = \frac{\Gamma(\frac{1}{7})\Gamma(\frac{2}{7})\Gamma(\frac{4}{7})}{7^{1/4}4\pi}$$

$$K(k_8) = \sqrt{\frac{2\sqrt{2}+\sqrt{1+5\sqrt{2}}}{4\sqrt{2}}}\ \frac{(\sqrt{2}+1)^{1/4}\Gamma(\frac{1}{8})\Gamma(\frac{3}{8})}{8\sqrt{\pi}}$$

$$K(k_9) = \frac{3^{1/4}\sqrt{2+\sqrt{3}}}{12\sqrt{\pi}\Gamma^2(\frac{1}{4})}$$

$$K(k_{10}) = \sqrt{(2+3\sqrt{2}+\sqrt{5})} \times \sqrt{\frac{\Gamma(\frac{1}{40})\Gamma(\frac{7}{40})\Gamma(\frac{9}{40})\Gamma(\frac{11}{40})\Gamma(\frac{13}{40})\Gamma(\frac{19}{40})\Gamma(\frac{23}{40})\Gamma(\frac{37}{40})}{256\pi^3}}$$

$$K(k_{11}) = [2+(17+3\sqrt{33})^{1/3}-(3\sqrt{33}-17)^{1/3}]^2 \times \frac{\Gamma(\frac{1}{11})\Gamma(\frac{3}{11})\Gamma(\frac{4}{11})\Gamma(\frac{5}{11})\Gamma(\frac{9}{11})}{11^{1/4}144\pi^2}$$

$$K(k_{12}) = \frac{3^{1/4}(\sqrt{2}+1)(\sqrt{3}+\sqrt{2})\sqrt{2-\sqrt{3}}\,\Gamma^3(\frac{1}{3})}{2^{13/3}\pi}$$

$$K(k_{13}) = \frac{(18+5\sqrt{13})^{1/4}}{\sqrt{6656\pi^5}} \times \sqrt{\Gamma(\tfrac{1}{52})\Gamma(\tfrac{7}{52})\Gamma(\tfrac{9}{52})\Gamma(\tfrac{11}{52})\Gamma(\tfrac{15}{52})\Gamma(\tfrac{17}{52})\Gamma(\tfrac{19}{52})\Gamma(\tfrac{25}{52})\Gamma(\tfrac{29}{52})\Gamma(\tfrac{31}{52})\Gamma}$$

$$K(k_{15}) = \sqrt{\frac{(\sqrt{5}+1)\Gamma(\frac{1}{15})\Gamma(\frac{2}{15})\Gamma(\frac{4}{15})\Gamma(\frac{8}{15})}{240\pi}}$$

$$K(k_{16}) = \frac{(2^{1/4}+1)^2\Gamma^2(\frac{1}{4})}{2^{9/2}\sqrt{\pi}}$$

$$K(k_{17}) = C_1\left[\frac{\Gamma(\frac{1}{68})\Gamma(\frac{3}{68})\Gamma(\frac{7}{68})\Gamma(\frac{11}{68})\Gamma(\frac{13}{68})}{\Gamma(\frac{5}{68})\Gamma(\frac{15}{68})\Gamma(\frac{19}{68})\Gamma(\frac{29}{68})}\right]^{1/4} \times [\Gamma(\tfrac{21}{68})\Gamma(\tfrac{25}{68})\Gamma(\tfrac{27}{68})\Gamma(\tfrac{31}{68})\Gamma(\tfrac{33}{68})]^{1/4}$$

$$K(k_{25}) = \frac{\sqrt{5}+2}{20}\,\frac{\Gamma^2(\frac{1}{4})}{\sqrt{\pi}},$$

where $\Gamma(z)$ is the GAMMA FUNCTION and C_1 is an algebraic number (Borwein and Borwein 1987, p. 298).

Borwein and Zucker (1992) give amazing expressions for singular values of complete elliptic integrals in terms of CENTRAL BETA FUNCTIONS

$$\beta(p) \equiv B(p,\ p). \tag{3}$$

Furthermore, they show that $K(k_n)$ is *always* expressible in terms of these functions for $n \equiv 1,\ 2 \pmod 4$. In such cases, the $\Gamma(z)$ functions appearing in the expression are OF THE FORM $\Gamma(t/4n)$ where $1 \leq t \leq (2n-1)$ and $(t, 4n) = 1$. The terms in the numerator depend on the sign of the KRONECKER SYMBOL $\{t/4n\}$. Values for the first few n are

$$K(k_1) = 2^{-2}\beta(\tfrac{1}{4})$$

$$K(k_2) = 2^{-13/4}\beta(\tfrac{1}{8})$$

$$K(k_3) = 2^{-4/3}3^{-1/4}\beta(\tfrac{1}{3}) = 2^{-5/3}3^{-3/4}\beta(\tfrac{1}{6})$$

$$K(k_5) = 2^{-33/20}5^{-5/8}(11+5\sqrt{5})^{1/4}\sin(\tfrac{1}{20}\pi)\beta(\tfrac{1}{2})$$

$$= 2^{-29/20}5^{-3/8}(1+\sqrt{5})^{1/4}\sin(\tfrac{3}{20}\pi)\beta(\tfrac{3}{20})$$

$$K(k_6) = 2^{-47/12}3^{-3/4}(\sqrt{2}-1)(\sqrt{3}+1)\beta(\tfrac{1}{24})$$

$$= 2^{-43/12}3^{-1/4}(\sqrt{3}-1)\beta(\tfrac{5}{24})$$

$$K(k_7) = 2\cdot 7^{-3/4}\sin(\tfrac{1}{7}\pi)\sin(\tfrac{2}{7}\pi)B(\tfrac{1}{7},\ \tfrac{2}{7})$$

$$= 2^{-2/7}7^{-1/4}\,\frac{\beta(\frac{1}{7})\beta(\frac{2}{7})}{\beta(\frac{1}{14})}$$

$$K(k_{10}) = 2^{-61/20}5^{-1/4}(\sqrt{5}-2)^{1/2}(\sqrt{10}+3)\,\frac{\beta(\frac{1}{8})\beta(\frac{7}{40})}{\beta(\frac{1}{3}40)}$$

$$= 2^{-15/4}5^{-3/4}(\sqrt{5}-2)^{1/2}\,\frac{\beta(\frac{1}{40})\beta(\frac{1}{9}40)}{\beta(\frac{3}{8})}$$

$$K(k_{11}) = R\cdot 2^{-7/11}\sin(\tfrac{1}{11}\pi)\sin(\tfrac{3}{11}\pi)B(\tfrac{1}{22},\ \tfrac{3}{22})$$

$$K(k_{13}) = 2^{-3}13^{-5/8}(5\sqrt{13}+18)^{1/4}$$

$$\times[\tan(\tfrac{1}{52}\pi)\tan(\tfrac{3}{52}\pi)\tan(\tfrac{9}{52}\pi)]^{1/2}\,\frac{\beta\left(\frac{1}{52}\right)\beta\left(\frac{9}{52}\right)}{\beta\left(\frac{23}{52}\right)}$$

$$K(k_{14}) = \sqrt{\sqrt{4\sqrt{2}+2}+\sqrt{2}+\sqrt{2\sqrt{2}-1}}$$

$$\cdot\, 2^{-13/4}7^{-3/8}\left[\frac{\tan(\frac{5}{56}\pi)\tan(\frac{13}{56}\pi)}{\tan(\frac{11}{56}\pi)}\right]^{1/4}$$

$$\times\sqrt{\frac{\beta(\frac{5}{56})\beta(\frac{13}{56})\beta(\frac{1}{8})}{\beta(\frac{11}{56})}}$$

$$K(k_{15}) = 2^{-1}3^{-3/4}5^{-7/12}B(\tfrac{1}{15},\ \tfrac{4}{15})$$

$$= \frac{2^{-2}3^{-3/4}5^{-3/4}(\sqrt{5}-1)\beta(\frac{1}{15})\beta(\frac{4}{15})}{\beta(\frac{1}{3})}$$

$$K(k_{17}) = C_2\left[\frac{\beta(\frac{1}{68})\beta(\frac{3}{68})\beta(\frac{7}{68})\beta(\frac{9}{68})\beta(\frac{11}{68})\beta(\frac{13}{68})}{\beta(\frac{5}{68})\beta(\frac{15}{68})}\right]^{1/4},$$

where R is the REAL ROOT of

$$x^3 - 4x = 4 = 0 \tag{4}$$

and C_2 is an algebraic number (Borwein and Zucker 1992). Note that $K(k_{11})$ is the only value in the above list which cannot be expressed in terms of CENTRAL BETA FUNCTIONS.

Using the ELLIPTIC ALPHA FUNCTION, the ELLIPTIC INTEGRALS OF THE SECOND KIND can also be found from

$$E = \frac{\pi}{4\sqrt{r}K} + \left[1 - \frac{\alpha(r)}{\sqrt{r}}\right]K \tag{5}$$

$$E' = \frac{\pi}{4k} + \alpha(r)K, \tag{6}$$

and by definition,

$$K' = K\sqrt{n}. \tag{7}$$

Elliptic Integral Singular Value k1

The first singular value k_1 of the ELLIPTIC INTEGRAL OF THE FIRST KIND $K(k)$, corresponding to

$$K'(k_1) = K(k_1), \tag{1}$$

is given by

$$k_1 = \frac{1}{\sqrt{2}} \tag{2}$$

$$k_1' = \frac{1}{\sqrt{2}}. \tag{3}$$

The value $K(k_1)$ is given by

$$K\left(\frac{1}{\sqrt{2}}\right) \equiv \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-\frac{1}{2}t^2)}}, \tag{4}$$

which can be transformed to

$$K\left(\frac{1}{\sqrt{2}}\right) = \sqrt{2}\int_0^1 \frac{dt}{\sqrt{1-t^4}}. \tag{5}$$

Let

$$u \equiv t^4 \tag{6}$$

$$du = 4t^3\,dt = 4u^{3/4}\,dt \tag{7}$$

$$dt = \tfrac{1}{4}u^{-3/4}\,du, \tag{8}$$

then

$$k\left(\frac{1}{\sqrt{2}}\right) = \frac{\sqrt{2}}{4}\int_0^1 u^{-3/4}(1-u)^{-1/2}\,du$$

$$= \frac{\sqrt{2}}{4}B(\tfrac{1}{4},\tfrac{1}{2}) = \frac{\Gamma(\frac{1}{4})\Gamma(\frac{1}{2})}{\Gamma(\frac{3}{4})}\,\frac{\sqrt{2}}{4}. \tag{9}$$

where $B(a, b)$ is the BETA FUNCTION and $\Gamma(z)$ is the GAMMA FUNCTION. Now use

$$\Gamma(\tfrac{1}{2}) = \sqrt{\pi} \tag{10}$$

and

$$\frac{1}{\Gamma(1-x)} = \frac{\sin(\pi x)}{\pi}\,\Gamma(x), \tag{11}$$

so

$$\frac{1}{\Gamma(\frac{3}{4})} = \frac{1}{\Gamma(1-\frac{1}{4})} = \frac{\sin\left(\frac{\pi}{4}\right)}{\pi}\,\Gamma(\tfrac{1}{4}) = \frac{1}{\pi\sqrt{2}}\,\Gamma(\tfrac{1}{4}). \tag{12}$$

Therefore,

$$K\left(\frac{1}{\sqrt{2}}\right) = \frac{\Gamma^2(\frac{1}{4})\sqrt{\pi}\sqrt{2}}{4\pi\sqrt{2}} = \frac{\Gamma^2(\frac{1}{4})}{4\sqrt{\pi}}. \tag{13}$$

Now consider

$$E\left(\frac{1}{\sqrt{2}}\right) \equiv \int_0^1 \sqrt{\frac{1-\frac{1}{2}t^2}{1-t^2}}\,dt. \tag{14}$$

Let

$$t^2 \equiv 1-u^2 \tag{15}$$

$$2t\,dt = -2u\,du \tag{16}$$

$$dt = -\frac{1}{t}u\,du = u(1-u^2)^{-1/2}\,du, \tag{17}$$

so

$$E\left(\frac{1}{\sqrt{2}}\right) = \int_0^1 \sqrt{\frac{1-\frac{1}{2}(1-u^2)}{1-(1-u^2)}}\,u(1-u^2)^{-1/2}\,du$$

$$= \int_0^1 \sqrt{\frac{\frac{1}{2}(1+u^2)}{u}}\,u(1-u^2)^{-1/2}\,du$$

$$= \frac{1}{\sqrt{2}}\int_0^1 \sqrt{\frac{(1+u^2)}{(1-u^2)}}\,du. \tag{18}$$

Now note that

$$\left(\frac{1}{\sqrt{1-u^4}} + \frac{u^2}{\sqrt{1-u^4}}\right)^2 = \frac{(1+u^2)^2}{1-u^4} = \frac{(1+u^2)^2}{(1+u^2)(1-u^2)}$$
$$= \frac{1+u^2}{1-u^2}, \tag{19}$$

so

$$E\left(\frac{1}{\sqrt{2}}\right) = \frac{1}{\sqrt{2}}\int_0^1 \sqrt{\frac{1+u^2}{1-u^2}}\,du$$

$$= \frac{1}{\sqrt{2}}\int_0^1 \left(\frac{1}{\sqrt{1-u^4}} + \frac{u^2}{\sqrt{1-u^4}}\right)du$$

$$= \frac{1}{2}K\left(\frac{1}{\sqrt{2}}\right) + \frac{1}{\sqrt{2}}\int_0^1 \frac{u^2\,du}{\sqrt{1-u^4}}. \tag{20}$$

Now let

$$t \equiv u^4 \tag{21}$$

$$dt = 4u^3\,du, \tag{22}$$

so

$$\int_0^1 \frac{u^2\,du}{\sqrt{1-u^4}} = \frac{1}{4}\int_0^1 t^{1/2}t^{-3/4}(1-t)^{-1/2}\,dt$$

$$= \tfrac{1}{4}\int_0^1 t^{-1/4}(1-t)^{-1/2}\,dt$$

$$= \tfrac{1}{4}B(\tfrac{3}{4},\tfrac{1}{2}) = \frac{\Gamma(\frac{3}{4})\Gamma(\frac{1}{2})}{4\Gamma(\frac{5}{4})}. \tag{23}$$

But

$$[\Gamma(\tfrac{5}{4})]^{-1} = [\tfrac{1}{4}\Gamma(\tfrac{1}{4})]^{-1} \tag{24}$$

$$\Gamma(\tfrac{3}{4}) = \pi\sqrt{2}[\Gamma(\tfrac{1}{4})]^{-1} \tag{25}$$

$$\Gamma(\tfrac{1}{2}) = \sqrt{\pi}, \tag{26}$$

so

$$\int_0^1 \frac{u^2\,du}{\sqrt{1-u^4}} = \frac{1}{4}\,\frac{\pi\sqrt{2}\cdot 4\sqrt{\pi}}{\Gamma^2(\frac{1}{4})} = \frac{\sqrt{2}\,\pi^{3/2}}{\Gamma^2(\frac{1}{4})} \tag{27}$$

$$E\left(\frac{1}{\sqrt{2}}\right) = \tfrac{1}{2}K + \frac{\pi^{3/2}}{\Gamma^2(\frac{1}{4})} = \frac{\Gamma^2(\frac{1}{4})}{8\sqrt{\pi}} + \frac{\pi^{3/2}}{\Gamma^2(\frac{1}{4})}$$

$$= \frac{1}{4}\sqrt{\frac{\pi}{2}}\left[\frac{\Gamma(\frac{1}{4})}{\Gamma(\frac{3}{4})} + \frac{\Gamma(\frac{3}{4})}{\Gamma(\frac{5}{4})}\right]. \tag{28}$$

Summarizing (13) and (28) gives

$$K\left(\frac{1}{\sqrt{2}}\right) = \frac{\Gamma^2(\frac{1}{4})}{4\sqrt{\pi}}$$

$$K'\left(\frac{1}{\sqrt{2}}\right) = \frac{\Gamma^2(\frac{1}{4})}{4\sqrt{\pi}}$$

$$E\left(\frac{1}{\sqrt{2}}\right) = \frac{\Gamma^2(\frac{1}{4})}{8\sqrt{\pi}} + \frac{\pi^{3/2}}{\Gamma^2(\frac{1}{4})}$$

$$E'\left(\frac{1}{\sqrt{2}}\right) = \frac{\Gamma^2(\frac{1}{4})}{8\sqrt{\pi}} + \frac{\pi^{3/2}}{\Gamma^2(\frac{1}{4})}.$$

Elliptic Integral Singular Value k2

The second SINGULAR VALUE k_2, corresponding to

$$K'(k_2) = \sqrt{2}K(k_2), \tag{1}$$

is given by

$$k_2 = \tan\left(\frac{\pi}{8}\right) = \sqrt{2}-1, \tag{2}$$

$$k_2' = \sqrt{2}(\sqrt{2}-1). \tag{3}$$

For this modulus,

$$E(\sqrt{2}-1) = \frac{1}{4}\sqrt{\frac{\pi}{4}}\left[\frac{\Gamma(\frac{1}{8})}{\Gamma(\frac{5}{8})} + \frac{\Gamma(\frac{5}{8})}{\Gamma(\frac{9}{8})}\right]. \tag{4}$$

Elliptic Integral Singular Value k3

The third SINGULAR VALUE k_3, corresponding to

$$K'(k_3) = \sqrt{3}K(k_3), \tag{1}$$

is given by

$$k_3 = \sin\left(\frac{\pi}{12}\right) = \tfrac{1}{4}(\sqrt{6}-\sqrt{2}). \tag{2}$$

As shown by Legendre,

$$K(k_3) = \frac{\sqrt{\pi}}{2\cdot 3^{3/4}}\,\frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})} \tag{3}$$

(Whittaker and Watson 1990, p. 525). In addition,

$$E(k_3) = \frac{\pi}{4\sqrt{3}}\,\frac{1}{K} + \frac{\sqrt{3}+1}{2\sqrt{3}}\,K$$

$$= \frac{1}{4}\left(\frac{\pi}{\sqrt{3}}\right)^{1/2}\left[\left(1+\frac{1}{\sqrt{3}}\right)\frac{\Gamma(\frac{1}{3})}{\Gamma(\frac{5}{6})} + \frac{2\Gamma(\frac{5}{6})}{\Gamma(\frac{1}{3})}\right], \tag{4}$$

and

$$E'(k_3) = \frac{\pi\sqrt{3}}{4}\,\frac{1}{K'(k_3)} + \frac{\sqrt{3}-1}{2\sqrt{3}}\,K'(k_3). \tag{5}$$

Summarizing,

$$K[\tfrac{1}{4}(\sqrt{6}-\sqrt{2})] = \frac{\sqrt{\pi}}{2\cdot 3^{3/4}}\,\frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})} \tag{6}$$

$$K'[\tfrac{1}{4}(\sqrt{6}-\sqrt{2})] = \sqrt{3}K = \frac{\sqrt{\pi}}{2\cdot 3^{1/4}}\,\frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})} \tag{7}$$

$$E[\tfrac{1}{4}(\sqrt{6}-\sqrt{2})]$$

$$= \frac{1}{4}\left(\frac{\pi}{\sqrt{3}}\right)^{1/2}\left[\left(1+\frac{1}{\sqrt{3}}\right)\frac{\Gamma(\frac{1}{3})}{\Gamma(\frac{5}{6})} + \frac{2\Gamma(\frac{5}{6})}{\Gamma(\frac{1}{3})}\right] \tag{8}$$

$$E'[\tfrac{1}{4}(\sqrt{6}-\sqrt{2})] = \frac{\sqrt{\pi}}{2}\left[3^{3/4}\,\frac{\Gamma(\frac{2}{3})}{\Gamma(\frac{1}{6})} + \frac{\sqrt{3}-1}{2\cdot 3^{3/4}}\,\frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})}\right]. \tag{9}$$

(Whittaker and Watson 1990).

Elliptic Lambda Function

The λ GROUP is the SUBGROUP of the GAMMA GROUP with a and d ODD; b and c EVEN. The function

$$\lambda(\tau) \equiv \lambda(q) \equiv k^2(q) = \frac{\vartheta_2^4(0,\ q)}{\vartheta_3^4(0,\ q)}, \tag{1}$$

where the NOME q is given by

$$q \equiv e^{i\pi r} \tag{2}$$

is a λ-MODULAR FUNCTION defined on the UPPER HALF-PLANE and $\vartheta_i(z,\ q)$ are THETA FUNCTIONS. The lambda elliptic function is given by the *Mathematica* command ModularLambda[*tau*], and satisfies the functional equations

$$\lambda(\tau + 2) = \lambda(\tau) \tag{3}$$

$$\lambda\left(\frac{\tau}{2\tau+1}\right) = \lambda(\tau). \tag{4}$$

$\lambda^*(r)$ gives the value of the MODULUS k_r for which the complementary and normal complete ELLIPTIC INTEGRALS OF THE FIRST KIND are related by

$$\frac{K'(k_r)}{K(k_r)} = \sqrt{r}. \tag{5}$$

It can be computed from

$$\lambda^*(r) \equiv k(q) = \frac{\vartheta_2^2(q)}{\vartheta_3^2(q)}, \tag{6}$$

where

$$q \equiv e^{-\pi\sqrt{r}}, \tag{7}$$

and ϑ_i is a JACOBI THETA FUNCTION.

From the definition of the lambda function,

$$\lambda^*(r') = \lambda^*\left(\frac{1}{r}\right) = \lambda^{*\prime}(r). \tag{8}$$

For all rational r, $K(\lambda^*(r))$ and $E(\lambda^*(r))$ are expressible in terms of a finite number of GAMMA FUNCTIONS (Selberg and Chowla 1967). $\lambda^*(r)$ is related to the RAMANUJAN g- AND G-FUNCTIONS by

$$\lambda^*(n) = \tfrac{1}{2}\left(\sqrt{1+G_n^{-12}} - \sqrt{1-G_n^{-12}}\right) \tag{9}$$

$$\lambda^*(n) = g_n^6\left(\sqrt{g_n^{12}+g_n^{-12}} - g_n^6\right). \tag{10}$$

Special values are

$$\lambda^*(\tfrac{2}{29}) = \left(13\sqrt{58}-99\right)\left(\sqrt{2}+1\right)^6$$

$$\lambda^*(\tfrac{2}{5}) = \left(\sqrt{10}-3\right)\left(\sqrt{2}+1\right)^2$$

$$\lambda^*(\tfrac{2}{3}) = \left(2-\sqrt{3}\right)\left(\sqrt{2}+\sqrt{3}\right)$$

$$\lambda^*(\tfrac{3}{4}) = \left(\sqrt{3}-\sqrt{2}\right)^2\left(\sqrt{2}+1\right)^2$$

$$\lambda^*(1) = \frac{1}{\sqrt{2}}$$

$$\lambda^*(2) = \sqrt{2}-1$$

$$\lambda^*(3) = \tfrac{1}{4}\sqrt{2}\left(\sqrt{3}-1\right)$$

$$\lambda^*(4) = 3-2\sqrt{2}$$

$$\lambda^*(5) = \tfrac{1}{2}\left(\sqrt{\sqrt{5}-1} - \sqrt{3-\sqrt{5}}\right)$$

$$\lambda^*(6) = \left(2-\sqrt{3}\right)\left(\sqrt{3}-\sqrt{2}\right)$$

$$\lambda^*(7) = \tfrac{1}{8}\sqrt{2}\left(3-\sqrt{7}\right)$$

$$\lambda^*(8) = \left(\sqrt{2}+1-\sqrt{2\sqrt{2}+2}\right)^2$$

$$\lambda^*(9) = \tfrac{1}{2}\left(\sqrt{2}-3^{1/4}\right)\left(\sqrt{3}-1\right)$$

$$\lambda^*(10) = \left(\sqrt{10}-3\right)\left(\sqrt{2}-1\right)^2$$

$$\lambda^*(11) = \tfrac{1}{12}\sqrt{6} \times \left(\sqrt{1+2x_{11}-4x_{11}^{-1}} - \sqrt{11+2x_{11}-4x_{11}^{-1}}\right)$$

$$\lambda^*(12) = \left(\sqrt{3}-\sqrt{2}\right)^2\left(\sqrt{2}-1\right)^2 = 15-10\sqrt{2}+8\sqrt{3}-6\sqrt{6}$$

$$\lambda^*(13) = \tfrac{1}{2}\left(\sqrt{5\sqrt{13}-17} - \sqrt{19-5\sqrt{13}}\right)$$

$$\lambda^*(14) = -11-8\sqrt{2}-2\left(\sqrt{2}+2\right)\sqrt{5+4\sqrt{2}} + \sqrt{11+8\sqrt{2}}\left(2+2\sqrt{2}+\sqrt{2}\sqrt{5+4\sqrt{2}}\right)$$

$$\lambda^*(15) = \tfrac{1}{16}\sqrt{2}\left(3-\sqrt{5}\right)\left(\sqrt{5}-\sqrt{3}\right)\left(2-\sqrt{3}\right)$$

$$\lambda^*(16) = \frac{(2^{1/4}-1)^2}{(2^{1/4}+1)^2}$$

$$\lambda^*(17) = \tfrac{1}{4}\sqrt{2}(42+10\sqrt{17}-13\sqrt{-3+\sqrt{17}}\sqrt{5+\sqrt{17}}$$

$$-3\sqrt{17}\sqrt{-3+\sqrt{17}}\sqrt{5+\sqrt{17}}$$

$$-\sqrt{-38-10\sqrt{17}+13\sqrt{-3+\sqrt{17}}\sqrt{5+\sqrt{17}}}$$

$$+3\sqrt{17}\sqrt{-3+\sqrt{17}}\sqrt{5+\sqrt{17}})$$

$$\lambda^*(18) = \left(\sqrt{2}-1\right)^3\left(2-\sqrt{3}\right)^2$$

$$\lambda^*(22) = \left(3\sqrt{11}-7\sqrt{2}\right)\left(10-3\sqrt{11}\right)$$

$$\lambda^*(30) = \left(\sqrt{3}-\sqrt{2}\right)^2\left(2-\sqrt{3}\right)\left(\sqrt{6}-\sqrt{5}\right)\left(4-\sqrt{15}\right)$$

$$\lambda^*(34) = \left(\sqrt{2}-1\right)^2\left(3\sqrt{2}-\sqrt{17}\right) \times \left(\sqrt{297+72\sqrt{17}}-\sqrt{296+72\sqrt{17}}\right)$$

$$\lambda^*(42) = \left(\sqrt{2}-1\right)^2\left(2-\sqrt{3}\right)^2\left(\sqrt{7}-\sqrt{6}\right)\left(8-3\sqrt{7}\right)$$

$$\lambda^*(58) = \left(13\sqrt{58}-99\right)\left(\sqrt{2}-1\right)^6$$

$$\lambda^*(210) = \left(\sqrt{2}-1\right)^2\left(2-\sqrt{3}\right)\left(\sqrt{7}-\sqrt{6}\right)^2\left(8-3\sqrt{7}\right) \times \left(\sqrt{10}-3\right)^2\left(4-\sqrt{15}\right)^2\left(\sqrt{15}-\sqrt{14}\right)\left(6-\sqrt{35}\right),$$

where

$$x_{11} \equiv \left(17+3\sqrt{33}\right)^{1/3}.$$

In addition,

$$\lambda^*(1') = \frac{1}{\sqrt{2}}$$
$$\lambda^*(2') = \sqrt{2\sqrt{2}-2}$$
$$\lambda^*(3') = \tfrac{1}{4}\sqrt{2}\left(\sqrt{3}+1\right)$$
$$\lambda^*(4') = 2^{1/4}\left(2\sqrt{2}-2\right)$$
$$\lambda^*(5') = \tfrac{1}{2}\left(\sqrt{\sqrt{5}-1}+\sqrt{3-\sqrt{5}}\right)$$
$$\lambda^*(7') = \tfrac{1}{8}\sqrt{2}\left(3+\sqrt{7}\right)$$
$$\lambda^*(9') = \tfrac{1}{2}\left(\sqrt{2}+3^{1/4}\right)\left(\sqrt{3}-1\right)$$
$$\lambda^*(12') = 2\sqrt{-208+147\sqrt{2}-120\sqrt{3}+85\sqrt{6}}.$$

Elliptic Logarithm

A generalization of integrals of the form

$$\int_{\infty}^{x} \frac{dt}{\sqrt{t^2+at}},$$

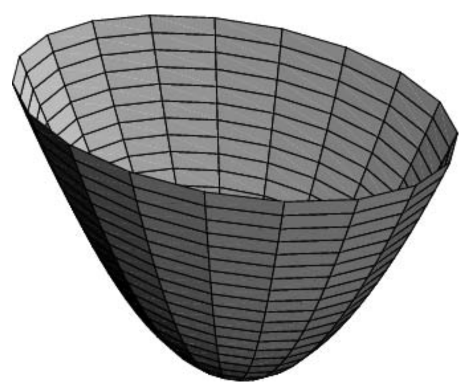
which can be expressed in terms of logarithmic and inverse trigonometric functions to

$$\operatorname{eln}(x) \equiv \int_{x}^{\infty} \frac{dt}{\sqrt{t^3+at^2+bt}}.$$

The inverse of the elliptic logarithm is the Elliptic Exponential Function.

Elliptic Modular Function

Modular Function



Elliptic Modulus

Modulus (Elliptic Integral)

Elliptic Nome

Nome

Elliptic Paraboloid

A Quadratic Surface which has Elliptical Cross Section. The elliptic paraboloid of height h, Semimajor Axis a, and Semiminor Axis b can be specified parametrically by

$$x = a\sqrt{u}\cos v$$
$$y = b\sqrt{u}\sin v$$
$$z = u.$$

for $v \in [0, 2\pi)$ and $u \in [0, h]$.

Elliptic Partial Differential Equation

A second-order PARTIAL DIFFERENTIAL EQUATION, i.e., one OF THE FORM

$$Au_{xx}+2Bu_{xy}+Cu_{yy}+Du_x+Eu_y+F=0, \qquad (1)$$

is called elliptic if the MATRIX

$$Z \equiv \begin{bmatrix} A & B \\ B & C \end{bmatrix} \qquad (2)$$

is POSITIVE DEFINITE. Elliptic partial differential equations have applications in almost all areas of mathematics, from harmonic analysis to geometry to Lie theory, as well as numerous applications in physics. As with a general PDE, elliptic PDE may have non-constant coefficients and be non-linear. Despite this variety, the elliptic equations have a well-developed theory.

The basic example of an elliptic partial differential equation is LAPLACE'S EQUATION

$$\nabla^2 u = 0 \qquad (3)$$

in n-dimensional Euclidean space, where the LAPLACIAN ∇^2 is defined by

$$\nabla^2 = \sum_{i=1}^{n} \frac{\partial^2}{\partial x_i^2}.$$

Other examples of elliptic equations include the nonhomogeneous POISSON'S EQUATION

$$\nabla^2 u = f(x) \qquad (4)$$

and the non-linear minimal surface equation.

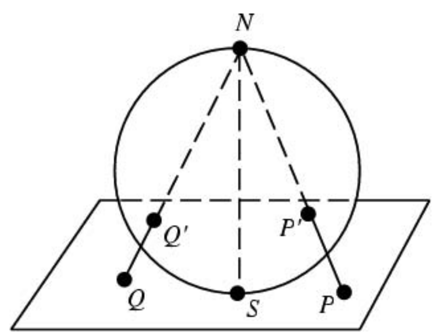
For an elliptic partial differential equation, BOUNDARY CONDITIONS are used to give the constraint $u(x, y)=g(x, y)$ on $\partial\Omega$, where

$$u_{xx}+u_{yy}=f(u_x, u_y, u, x, y) \qquad (5)$$

holds in Ω.

One property of constant coefficient elliptic equations is that their solutions can be studied using the FOURIER TRANSFORM. Consider POISSON'S EQUATION with periodic $f(x)$. The FOURIER SERIES expansion is then given by

$$-|\zeta|^2 \hat{u}(\zeta) = \hat{f}(\zeta), \qquad (6)$$



where $|\zeta|^2$ is called the "principal symbol," and so we can solve for u. Except for $\zeta = 0$, the multiplier is nonzero.

In general, a PDE may have non-constant coefficients or even be non-linear. A linear PDE is elliptic if its principal symbol, as in the theory of PSEUDODIFFERENTIAL OPERATORS, is nonzero away from the origin. For instance, (3) has as its principal symbol $|\zeta|^4$, which is non-zero for $|\zeta| \neq 0$, and is an elliptic PDE.

A nonlinear PDE is elliptic at a solution u if its linearization is elliptic at u. One simply calls a nonlinear equation elliptic if it is elliptic at any solution, such as in the case of harmonic maps between Riemannian manifolds.

Elliptic Plane

The REAL PROJECTIVE PLANE with elliptic METRIC where the distance between two points P and Q is defined as the RADIAN ANGLE between the projection of the points on the surface of a SPHERE (which is tangent to the plane at a point S) from the ANTIPODE N of the tangent point.

References

Coxeter, H. S. M. *Introduction to Geometry, 2nd ed.* New York: Wiley, p. 94, 1969.

Elliptic Point

A point $\mathbf{p}$ on a REGULAR SURFACE $M \in \mathbb{R}^3$ is said to be elliptic if the GAUSSIAN CURVATURE $K(\mathbf{p}) > 0$ or equivalently, the PRINCIPAL CURVATURES κ_1 and κ_2 have the same sign.

Elliptic Pseudoprime

Let E be an ELLIPTIC CURVE defined over the FIELD of RATIONAL NUMBERS $\mathbb{Q}\left(\sqrt{-d}\right)$ having equation

$$y^2 = x^3 + ax + b$$

with a and b INTEGERS. Let P be a point on E with integer coordinates and having infinite order in the additive group of rational points of E, and let n be a COMPOSITE NATURAL NUMBER such that $(-d/n) = -1$, where $(-d/n)$ is the JACOBI SYMBOL. Then if

$$(n+1)P \equiv 0 \pmod{n},$$

n is called an elliptic pseudoprime for (E, P).

Elongated Square Gyrobicupola

A nonuniform POLYHEDRON obtained by rotating the bottom third of a SMALL RHOMBICUBOCTAHEDRON (Ball and Coxeter 1987, p. 137). It is also called Miller's solid, the Miller-askinuze solid, or the pseudorhombicuboctahedron, and is JOHNSON SOLID J_{37}.

Although some writers have suggested that the elongated square gyrobicupola should be considered a fourteenth ARCHIMEDEAN SOLID, its twist allows vertices "near the equator" and those "in the polar regions" to be distinguished. Therefore, it is not a true Archimedean like the SMALL RHOMBICUBOCTAHEDRON, whose vertices *cannot* be distinguished (Cromwell 1997, pp. 91–2).

Elsasser Function

$$E(y,\ u) \equiv \int_{-1/2}^{1/2} \exp\left[-\frac{2\pi y u \sinh(2\pi y)}{\cosh(2\pi y) - \cos(2\pi x)}\right] dx.$$

Embeddable Knot

A KNOT K is an n-embeddable knot if it can be placed on a GENUS n standard embedded surface without crossings, but K cannot be placed on any standardly embedded surface of lower GENUS without crossings. Any KNOT is an n-embeddable knot for some n. The FIGURE-OF-EIGHT KNOT is a 2-EMBEDDABLE KNOT. A knot with BRIDGE NUMBER b is an n-embeddable knot where $n \le b$.

See also EMBEDDABLE SURFACE, TUNNEL NUMBER

Embeddable Surface

EMBEDDED SURFACE

Embedded Surface

A SURFACE S is n-embeddable if it can be placed in $\mathbb{R}^n$-space without self-intersections, but cannot be similarly placed in any $\mathbb{R}^k$ for $k < n$. A surface so embedded is said to be an embedded surface. The COSTA MINIMAL SURFACE is embeddable in $\mathbb{R}^3$, but the KLEIN BOTTLE is not (the commonly depicted $\mathbb{R}^3$ representation requires the surface to pass through itself).

There is particular interest in surfaces which are minimal, complete, and embedded.

Embedding

An embedding is a representation of a topological object, MANIFOLD, GRAPH, FIELD, etc. in a certain space in such a way that its connectivity or algebraic properties are preserved. For example, a FIELD embedding preserves the algebraic structure of plus and times, an embedding of a TOPOLOGICAL SPACE preserves OPEN SETS, and a GRAPH EMBEDDING preserves connectivity.

One space X is embedded in another space Y when the properties of Y restricted to X are the same as the properties of X. For example, the rationals are embedded in the reals, and the integers are embedded in the rationals. In geometry, the sphere is embedded in $\mathbb{R}^3$ as the unit sphere.

Empty Graph

An empty graph on n nodes consists of n isolated nodes with no edges. The empty graph on 0 nodes is called the NULL GRAPH. The empty graph on n vertices is the complement of the COMPLETE GRAPH K_n.

See also COMPLETE GRAPH, GRAPH, NULL GRAPH

References

Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, p. 141, 1990.

Empty Set

The SET containing no elements, denoted $\emptyset$. Strangely, the empty set is both OPEN and CLOSED for any SET X and TOPOLOGY.

A GROUPOID, SEMIGROUP, QUASIGROUP, RINGOID, and SEMIRING can be empty. MONOIDS, GROUPS, and RINGS must have at least one element, while DIVISION RINGS and FIELDS must have at least two elements.

See also SET, URELEMENT

Enantiomorph

ENANTIOMER

Enantiomorphous

Of opposite symmetry under reflection; MIRROR IMAGES.

See also DISSYMMETRIC, ENANTIOMER, MIRROR IMAGE

Encoding

An encoding is a way of representing a number or expression in terms of another (usually simpler) one. However, multiple expressions can also be encoded as a single expression, as in, for example,

$$(a,\ b) \equiv \tfrac{1}{2}[(a+b)^2 + 3a + b]$$

which encodes a and b uniquely as a single number.

a	b	(a, b)
0	0	0
0	1	1
1	0	2
0	2	3
1	1	4
2	0	5

See also CODE, CODING THEORY, HUFFMAN CODING, PRÜFER CODE, RUN-LENGTH ENCODING

Encroaching List Set

A structure consisting of an ordered set of sorted lists such that the head and tail entries of later lists nest within earlier ones. For example, an encroaching list set for $\{6, 7, 1, 8, 2, 5, 9, 3, 4\}$ is given by $\{\{1, 6, 7, 8, 9\}, \{2, 5\}, \{3, 4\}\}$. Encroaching list sets can be computed using `EncroachingListSet[l]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

It is conjectured that the number of encroaching lists associated with a RANDOM PERMUTATION of size n is $\sim \sqrt{2n}$ for sufficiently large n (Skiena 1988; Skiena 1990, p. 78).

Endogenous Variable

An economic variable which is independent of the relationships determining the equilibrium levels, but nonetheless affects the equilibrium.

See also EXOGENOUS VARIABLE

References

Iyanaga, S. and Kawada, Y. (Eds.). *Encyclopedic Dictionary of Mathematics.* Cambridge, MA: MIT Press, p. 458, 1980.

Endomorphism

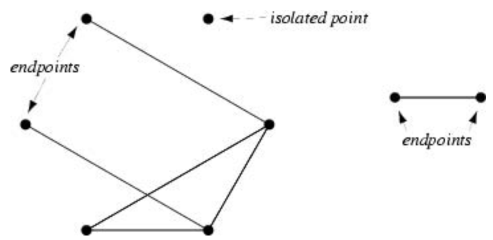
A SURJECTIVE MORPHISM from an object to itself. The term derives from the Greek adverb $\varepsilon\nu\delta o\nu$ (*endon*) "inside" and $\mu o\rho\varphi\omega\sigma\iota\varsigma$ (*morphosis*) "to form" or "to shape."

In ERGODIC THEORY, let X be a SET, F a SIGMA ALGEBRA on X and m a PROBABILITY MEASURE. A MAP $T : X \to X$ is called an endomorphism or MEASURE-PRESERVING TRANSFORMATION if

1. T is SURJECTIVE,
2. T is MEASURABLE,
3. $m(T^{-1}A) = m(A)$ for all $A \in F$.

An endomorphism is called ERGODIC if it is true that $T^{-1}A = A$ IMPLIES $m(A) = 0$ or 1, where $T^{-1}A = \{x \in X : T(x) \in A\}$.

See also MEASURABLE FUNCTION, MEASURE-PRESERVING TRANSFORMATION, MORPHISM, SIGMA ALGEBRA, SURJECTIVE



Endoscopy

Endrass Octic

Endraß surfaces are a pair of OCTIC SURFACES which have 168 ORDINARY DOUBLE POINTS. This is the maximum number known to exist for an OCTIC SURFACE, although the rigorous upper bound is 174. The equations of the surfaces $X_8^{\pm}$ are

$$64(x^2-w^2)(y^2-w^2)[(x+y)^2-2w^2]$$
$$[(x-y)^2-2w^2]-\{-4(1\pm\sqrt{2})(x^2+y^2)^2$$
$$+[8(2\pm\sqrt{2})z^2+2(2\pm 7\sqrt{2})w^2](x^2+y^2)$$
$$-16z^4+8(1\mp 2\sqrt{2})z^2w^2-(1+12\sqrt{2})w^4\}^2=0,$$

where w is a parameter taken as $w=1$ in the above plots. All ORDINARY DOUBLE POINTS of X_8^+ are real, while 24 of those in X_8^- are complex. The surfaces were discovered in a 5-D family of octics with 112 nodes, and are invariant under the GROUP $D_8 \otimes \mathbb{Z}_2$.

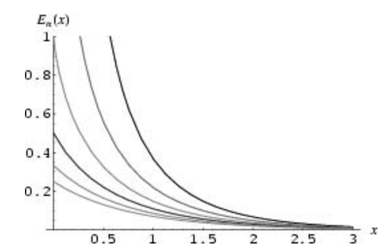
Energy

The term energy has an important physical meaning in physics and is an extremely useful concept. A much more abstract mathematical generalization is defined as follows. Let Ω be a SPACE with MEASURE $\mu \geq 0$ and let $\Phi(P, Q)$ be a real function on the PRODUCT SPACE $\Omega \times \Omega$. When

$$(\mu, \nu) = \int\int \Phi(P, Q)\, d\mu(Q)\, d\nu(P)$$



$$= \int \Phi(P, \mu)\, d\nu(P)$$

exists for measures $\mu, \nu \geq 0$, (μ, ν) is called the MUTUAL ENERGY and (μ, μ) is called the ENERGY.

See also DIRICHLET ENERGY, MUTUAL ENERGY

References
Iyanaga, S. and Kawada, Y. (Eds.). "General Potential." §335.B in *Encyclopedic Dictionary of Mathematics.* Cambridge, MA: MIT Press, p. 1038, 1980.

En-Function

The $\mathrm{E}_n(x)$ function is defined by the integral

$$\mathrm{E}_n(x) \equiv \int_1^{\infty} \frac{e^{-xt}\, dt}{t^n} \quad (1)$$

and is given by the *Mathematica* function `ExpIntegralE[n, x]`. Defining $t \equiv \eta^{-1}$ so that $dt = -\eta^{-2}\, d\eta$,

$$\mathrm{E}_n(x) = \int_0^1 e^{-x/\eta}\, \eta^{\eta-2}\, d\eta \quad (2)$$

$$\mathrm{E}_n(0) = \frac{1}{n-1}. \quad (3)$$

The function satisfies the RECURRENCE RELATIONS

$$\mathrm{E}_n'(x) = -\mathrm{E}_{n-1}(x) \quad (4)$$

$$n\mathrm{E}_{n+1}(x) = e^{-x} - x\mathrm{E}_n(x). \quad (5)$$

Equation (4) can be derived from

$$E_n(x) = \int_1^\infty \frac{e^{-tx}}{t^n}\,dt \tag{6}$$

$$E'_n(x) = \frac{d}{dx}\int_1^\infty \frac{e^{-tx}}{t^n}\,dt = \int_1^\infty \frac{d}{dx}\left(\frac{e^{-tx}}{t^n}\right)dt$$
$$= -\int_1^\infty t\frac{e^{-tx}}{t^n}\,dt$$
$$= -\int_1^\infty \frac{e^{-tx}}{t^{n-1}}\,dt = -E_{n-1}(x), \tag{7}$$

and (5) using INTEGRATION BY PARTS, letting

$$u = \frac{1}{t^n} \qquad dv = e^{-tx}\,dt \tag{8}$$

$$du = -\frac{n}{t^{n+1}}\,dt \qquad v = -\frac{e^{-tx}}{x} \tag{9}$$

gives

$$E_n(x) = \int_1^\infty u\,dv = [uv]_1^\infty - \int_1^\infty v\,du$$
$$= \left[-\frac{e^{-tx}}{xt^n}\right]_{t=1}^\infty - \frac{n}{x}\int_1^\infty \frac{e^{-tx}}{t^{n+1}}\,dt$$
$$= \left[0 - \left(-\frac{e^{-x}}{x}\right)\right] - \frac{n}{x}\int_1^\infty \frac{e^{-tx}}{t^{n+1}}\,dt$$
$$= \frac{e^{-x}}{x} - \frac{n}{x}E_{n+1}(x). \tag{10}$$

Solving (10) for $nE_{n+1}(x)$ then gives (5).

An ASYMPTOTIC SERIES is given by

$$(n-1)!E_n(x)$$
$$= (-x)^{n-1}E_1(x) + e^{-x}\sum_{s=0}^{n} -2(n-s-2)!(-x)^s, \tag{11}$$

so

$$E_n(x) = \frac{e^{-x}}{x}\left[1 - \frac{n}{x} + \frac{n(n+1)}{x^2} + \cdots\right]. \tag{12}$$

The special case $n = 1$ gives

$$E_1(x) \equiv -\mathrm{ei}(-x) = \int_1^\infty \frac{e^{-tx}dt}{t} = \int_x^\infty \frac{e^{-u}du}{u}, \tag{13}$$

where $\mathrm{ei}(x)$ is the EXPONENTIAL INTEGRAL, which is also equal to

$$E_1(x) = -\gamma - \ln x - \sum_{n=1}^\infty \frac{(-1)^n x^n}{n!n}, \tag{14}$$

where γ is the EULER-MASCHERONI CONSTANT.

$$E_1(0) = \infty \tag{15}$$

$$E_1(ix) = -\mathrm{ci}(x) + i\ \mathrm{si}(x), \tag{16}$$

where $\mathrm{ci}(x)$ and $\mathrm{si}(x)$ are the COSINE INTEGRAL and SINE INTEGRAL.

ENNEADECAGON

Enneper's Minimal Surface

A self-intersecting MINIMAL SURFACE which can be generated using the ENNEPER-WEIERSTRASS PARAMETERIZATION with

$$f(z) = 1 \quad (1)$$

$$g(z) = \zeta. \quad (2)$$

Letting $z = re^{i\phi}$ and taking the REAL PART give

$$x = \Re\left[re^{i\phi} - \tfrac{1}{3} r^3 e^{3i\phi}\right] \quad (3)$$

$$= r \cos\phi - \tfrac{1}{3} r^3 \cos(3\phi) \quad (4)$$

$$y = \Re[ire^{i\phi} + \tfrac{1}{3} ir^3 e^{3i\phi}] \quad (5)$$

$$= -\tfrac{1}{3} r[3 \sin\phi + r^2 \sin(3\phi)] \quad (6)$$

$$z = \Re[r^2 e^{2i\phi}] \quad (7)$$

$$= r^2 \cos(2\phi), \quad (8)$$

where $r \in [0, 1]$ and $\phi \in [-\pi, \pi)$. The coefficients of the FIRST FUNDAMENTAL FORM are

$$E = -2 \cos(2\phi) \quad (9)$$

$$F = 4r \cos\phi \sin\phi \quad (10)$$

$$G = 2r^2 \cos(2\phi), \quad (11)$$

the SECOND FUNDAMENTAL FORM coefficients are

$$e = (1 + r^2)^2 \quad (12)$$

$$f = 0 \quad (13)$$

$$g = r^2(1 + r^2)^2, \quad (14)$$

and the GAUSSIAN and MEAN CURVATURES are

$$K = -\frac{4}{(1 + r^2)^4} \quad (15)$$

$$H = 0. \quad (16)$$

Letting $z = u + iv$ gives the figure above, with parametrization

$$x = u - \tfrac{1}{3} u^3 + uv^2 \quad (17)$$

$$y = -v - u^2 v + \tfrac{1}{3} v^3 \quad (18)$$

$$z = u^2 - v^2 \quad (19)$$

(do Carmo 1986, Gray 1997, Nordstrand). In this parameterization, the coefficients of the FIRST FUNDAMENTAL FORM are

$$E = (1 + u^2 + v^2)^2 \quad (20)$$

$$F = 0 \quad (21)$$

$$G = (1 + u^2 + v^2)^2, \quad (22)$$

the SECOND FUNDAMENTAL FORM coefficients are

$$e = -2 \quad (23)$$

$$f = 0 \quad (24)$$

$$g = 2, \quad (25)$$

the AREA ELEMENT is

$$dA = (1 + u^2 + v^2)\, du \wedge dv, \quad (26)$$

and the GAUSSIAN and MEAN CURVATURES are

$$K = -\frac{4}{(1 + u^2 + v^2)^4} \quad (27)$$

$$H = 0. \quad (28)$$

Nordstrand gives the implicit form

$$\left(\frac{y^2 - x^2}{2z} + \tfrac{2}{9} z^2 + \tfrac{2}{3}\right)^3$$

$$-6\left[\frac{(y^2-x^2)}{4z}-\tfrac{1}{4}(x^2+y^2+\tfrac{8}{9}z^2)+\tfrac{2}{9}\right]^2=0. \qquad (29)$$

Enormous Theorem

CLASSIFICATION THEOREM

Enriques Surfaces

An Enriques surface X is a smooth compact complex surface having irregularity $q(X)=0$ and nontrivial canonical sheaf K_X such that $K_X^2=O_X$ (Endraß). Such surfaces cannot be embedded in projective 3-space, but there nonetheless exist transformations onto singular surfaces in projective 3-space. There exists a family of such transformed surfaces of degree six which passes through each edge of a TETRAHEDRON twice. A subfamily with tetrahedral symmetry is given by the two-parameter $(r,\ c)$ family of surfaces

$$f_r x_0x_1x_2x_3+c(x_0^2x_1^2x_2^2+x_0^2x_1^2x_3^2+x_0^2x_2^2x_3^2+x_1^2x_2^2x_3^2=0$$

and the polynomial f_r is a sphere with radius r,

$$f_r=(3-r)(x_0^2+x_1^2+x_2^2+x_3^2)$$

$$-2(1+r)(x_0x_1+x_0x_2+x_0x_3+x_1x_2+x_1x_3+x_2x_3)$$

(Endraß).

Entire Modular Form

A MODULAR FORM which is not allowed to have poles in the UPPER HALF-PLANE H or at $i\infty$.

See also MODULAR FORM

Entringer Number

The Entringer numbers $E(n,\ k)$ are the number of PERMUTATIONS of $\{1,\ 2,\ \ldots,\ n+1\}$, starting with $k+1$, which, after initially falling, alternately fall then rise. The Entringer numbers are given by

$$E(0,\ 0)=1$$
$$E(n,\ 0)=0$$

together with the RECURRENCE RELATION

$$E(n,\ k)=E(n,\ k+1)+E(n-1,\ n-k).$$

The numbers $E(n)=E(n,\ n)$ are the SECANT and TANGENT NUMBERS given by the MACLAURIN SERIES

$$\sec x+\tan x = A_0+A_1x+A_2\frac{x^2}{2!}+A_3\frac{x^3}{3!}A_4\frac{x^4}{4!}+A_5\frac{x^5}{5!}+\ldots.$$

Entropy

In physics, the word entropy has important physical implications as the amount of "disorder" of a system. In mathematics, a more abstract definition is used. The (Shannon) entropy of a variable X is defined as

$$H(X)\equiv-\sum_x p(x)\ \ln[p(x)],$$

where $p(x)$ is the probability that X is in the state x, and $p \ln p$ is defined as 0 if $p=0$. The joint entropy of variables X_1, ..., X_n is then defined by

$$H(X_1,\ \ldots,\ X_n) \equiv-\sum_{x_1}\cdots\sum_{x_n} p(x_1,\ \ldots,\ x_n)\ln[p(x_1,\ \ldots,\ x_n)].$$

Envelope

The envelope of a one-parameter family of curves given implicitly by

$$U(x, y, c) = 0, \tag{1}$$

or in parametric form by $(f(t, c), g(t, c))$, is a curve which touches every member of the family. For a curve represented by $(f(t, c), g(t, c))$, the envelope is found by solving

$$0 = \frac{\partial f}{\partial t}\frac{\partial g}{\partial c} - \frac{\partial f}{\partial c}\frac{\partial g}{\partial t}. \tag{2}$$

For a curve represented implicitly, the envelope is given by simultaneously solving

$$\frac{\partial U}{\partial c} = 0 \tag{3}$$

$$U(x, y, c) = 0. \tag{4}$$

Envelope (Form)

Given a differential p-form q in the exterior algebra $\wedge^p V^*$, its envelope is the smallest subspace W such that q is in the subspace $\wedge^p W^* \subset \wedge^p V^*$. Alternatively, W is spanned by the vectors that can be written as the contraction of q with an element of $\wedge^{p-1} V$.

For example, the envelope of dx in $V = \mathbb{R}^2$ is $W = \langle \partial/\partial x \rangle$, and the envelope of $dx_1 \wedge dx_2 + dx_3 \wedge dx_4$ in $V = \mathbb{R}^4$ is all of V.

Here is a *Mathematica* function which will compute the envelope of an antisymmetric tensor.

```
< <DiscreteMath`Combinatorica`;
ContractAll[a_List, b_List] :=   Module[{k =
TensorRank[a] - TensorRank[b]},   If[k >= 0,
Map[Flatten[#1].Flatten[b]   &,   a,   {k}],
ContractAll[b, a]
   ]
  ]  Envelope[a_List?VectorQ] := Select[{a},
#1    !=     Table[0,     {Length[a]}]     &]
Envelope[a_List] := Module[
  {
   z, inds, vects,
   d = Dimensions[a][[1]], r = TensorRank[a]
```

```
  },
  z = Table[0, ##1] & @@ Table[{d}, {r - 1}];
  inds = KSubsets[Range[d], r - 1];
 vects = Map[ContractAll[a, ReplacePart[z, 1,
#1]] &, inds];
 Select[RowReduce[vects], #1 != Table[0, {d}]
&]
 ]
```

Envelope Theorem

Relates EVOLUTES to single paths in the CALCULUS OF VARIATIONS. Proved in the general case by Darboux and Zermelo (1894) and Kneser (1898). It states: "When a single parameter family of external paths from a fixed point O has an ENVELOPE, the integral from the fixed point to any point A on the ENVELOPE equals the integral from the fixed point to any second point B on the ENVELOPE plus the integral along the envelope to the first point on the ENVELOPE, $J_{OA} = J_{OB} + J_{BA}$."

E-Operator

SUMMATION BY PARTS

e-Perfect Number

A number n is called an e-perfect number if $\sigma_e(n) = 2n$, where $\sigma_e(n)$ is the SUM of the E-DIVISORS of n. If m is SQUAREFREE, then $\sigma_e(m) = m$. As a result, if n is e-perfect and m is SQUAREFREE with $m \perp b$, then mn is e-perfect.

The first few e-perfect numbers are 36, 180, 252, 396, 468, ... (Sloane's A054979). There are no ODD e-perfect numbers. The first few primitive e-perfect numbers are 36, 1800, 2700, 17424, ... (Sloane's A054980).

Epicycloid

The path traced out by a point P on the edge of a CIRCLE of RADIUS b rolling on the outside of a CIRCLE of RADIUS a. An epicycloid is therefore an EPITROCHOID with $h = b$. Epicycloids are given by the PARAMETRIC EQUATIONS

$$x = (a+b)\cos\phi - b\cos\left(\frac{a+b}{b}\phi\right) \tag{1}$$

$$y = (a+b)\sin\phi - b\sin\left(\frac{a+b}{b}\phi\right). \tag{2}$$

A polar equation can be derived by computing

$$x^2 = (a+b)^2\cos^2\phi - 2b(a+b)\cos\phi\cos\left(\frac{a+b}{b}\phi\right) + b^2\cos^2\left(\frac{a+b}{b}\phi\right) \tag{3}$$

$$y^2 = (a+b)^2 \sin^2 \phi - 2b(a+b) \sin \phi \sin\left(\frac{a+b}{b} \phi\right)$$
$$+ b^2 \sin^2\left(\frac{a+b}{b} \phi\right), \tag{4}$$

so

$$r^2 = x^2 + y^2 = (a+b)^2 + b^2 - 2b(a+b)$$
$$\times \left\{ \cos\left[\left(\frac{a}{b}+1\right)\phi\right] \cos\ \phi + \sin\left[\left(\frac{a}{b}+1\right)\phi\right] \sin\ \phi \right\}. \tag{5}$$

But

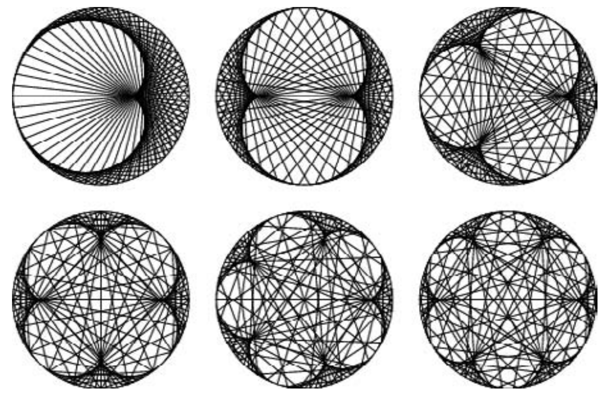
$$\cos \alpha \cos \beta + \sin \alpha \sin \beta = \cos(\alpha - \beta), \tag{6}$$

so

$$r^2 = (a+b)^2 + b^2 - 2b(a+b) \cos\left[\left(\frac{a}{b}+1\right)\phi - \phi\right]$$
$$= (a+b)^2 + b^2 - 2b(a+b) \cos\left(\frac{a}{b}\ \phi\right). \tag{7}$$

Note that ϕ is the parameter here, *not* the polar angle. The polar angle from the center is

$$\tan\ \theta = \frac{y}{x} = \frac{(a+b) \sin\ \phi - b \sin\left(\frac{a+b}{b}\ \phi\right)}{(a+b) \cos\ \phi - b \cos\left(\frac{a+b}{b}\ \phi\right)}. \tag{8}$$



To get n CUSPS in the epicycloid, $b = a/n$, because then n rotations of b bring the point on the edge back to its starting position.

$$r^2 = a^2 \left[\left(1+\frac{1}{n}\right)^2 + \left(\frac{1}{n}\right)^2 - 2\left(\frac{1}{n}\right)\left(1+\frac{1}{n}\right)\cos(n\phi)\right]$$
$$= a^2 \left[1 + \frac{2}{n} + \frac{1}{n^2} + \frac{1}{n^2} - \left(\frac{2}{n}\right)\left(\frac{n+1}{n}\right)\cos(n\phi)\right]$$
$$= a^2 \left[\frac{n^2+2n+2}{n^2} - \frac{2(n+1)}{n^2} \cos(n\phi)\right]$$
$$= \frac{a^2}{n^2}\left[(n^2+2n+2) - 2(n+1) \cos(n\phi)\right], \tag{9}$$

so

$$\tan\ \theta = \frac{a\left(\frac{n+1}{n}\right) \sin\ \phi - \frac{a}{n} \sin[(n+1)\phi]}{a\left(\frac{n+1}{n}\right) \cos\ \phi - \frac{a}{n} \cos[(n+1)\phi]}$$
$$= \frac{(n+1) \sin\ \phi - \sin[(n+1)\phi]}{(n+1) \cos\ \phi - \cos[(n+1)\phi]}. \tag{10}$$

An epicycloid with one cusp is called a CARDIOID, one with two cusps is called a NEPHROID, and one with five cusps is called a RANUNCULOID.

n-epicycloids can also be constructed by beginning with the DIAMETER of a CIRCLE, offsetting one end by a series of steps while at the same time offsetting the other end by steps n times as large. After traveling around the CIRCLE once, an n-cusped epicycloid is produced, as illustrated above (Madachy 1979).

Epicycloids have TORSION

$$\tau = 0 \tag{11}$$

and satisfy

$$\frac{s^2}{a^2} + \frac{\rho^2}{b^2} = 1, \tag{12}$$

where ρ is the RADIUS OF CURVATURE $(1/\kappa)$.

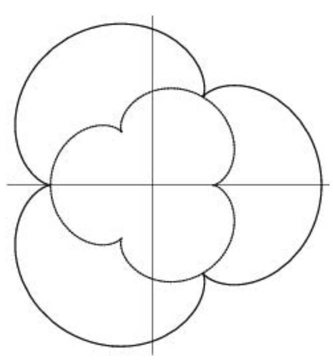
Epicycloid Evolute

The EVOLUTE of the EPICYCLOID

$$x = (a+b)\cos t - b\cos\left[\left(\frac{a+b}{b}\right)t\right]$$



$$y = (a+b)\sin t - b\sin\left[\left(\frac{a+b}{b}\right)t\right]$$

is another EPICYCLOID given by

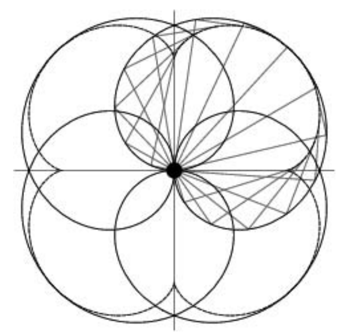
$$x = \frac{a}{a+2b}\left\{(a+b)\cos t + b\cos\left[\left(\frac{a+b}{b}\right)t\right]\right\}$$

$$y = \frac{a}{a+2b}\left\{(a+b)\sin t + b\cos\left[\left(\frac{a+b}{b}\right)t\right]\right\}.$$

Epicycloid Involute

The INVOLUTE of the EPICYCLOID

$$x = (a+b)\cos t - b\cos\left[\left(\frac{a+b}{b}\right)t\right]$$



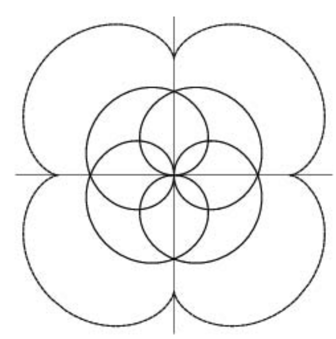
$$y = (a+b)\sin t - b\sin\left[\left(\frac{a+b}{b}\right)t\right]$$

is another EPICYCLOID given by

$$x = \frac{a+2b}{a}\left\{(a+b)\cos t + b\cos\left[\left(\frac{a+b}{b}\right)t\right]\right\}$$

$$y = \frac{a+2b}{a}\left\{(a+b)\sin t + b\cos\left[\left(\frac{a+b}{b}\right)t\right]\right\}.$$

Epicycloid Pedal Curve

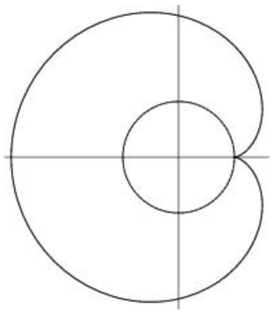


The PEDAL CURVE of an EPICYCLOID with PEDAL POINT at the center, shown for an epicycloid with four cusps, is not a ROSE as claimed by Lawrence (1972).

References

Lawrence, J. D. *A Catalog of Special Plane Curves.* New York: Dover, p. 204, 1972.

Epicycloid Radial Curve



The RADIAL CURVE of an EPICYCLOID is shown above for an epicycloid with four cusps. It is not a ROSE, as claimed by Lawrence (1972).

References

Lawrence, J. D. *A Catalog of Special Plane Curves.* New York: Dover, p. 202, 1972.

Epicycloid1-Cusped

A 1-cusped epicycloid has $b = a$, so $n = 1$. The radius measured from the center of the large circle for a 1-cusped epicycloid is given by EPICYCLOID equation (9) with $n = 1$ so

$$r^2 = \frac{a^2}{n^2}[(n^2+2n+2)-2(n+1)\cos(n\phi)]$$

$$= a^2[(1^2+2\cdot 1+2)-2(1+1)\cos(1\cdot\phi)]$$

$$= a^2(5-4\cos\phi) \quad (1)$$

$$r = a\sqrt{5-4\cos\phi}, \quad (2)$$

and

$$\tan\theta = \frac{2\sin\phi - \sin(2\phi)}{2\cos\phi - \cos(2\phi)}. \quad (3)$$

The 1-cusped epicycloid is just an offset CARDIOID.

Epicycloid–2-Cusped

NEPHROID

Epimenides Paradox

A version of the LIAR'S PARADOX, attributed to the philosopher Epimenides in the sixth century BC. "All Cretans are liars...One of their own poets has said so." This is not a true paradox since the poet may have knowledge that at least one Cretan is, in fact, honest, and so be lying when he says that *all* Cretans are liars. There therefore need be no self-contradiction in what could simply be a false statement by a person who is himself a liar.

A sharper version of the paradox (which has no such loophole) is the EUBULIDES PARADOX, "This statement is false."

See also EUBULIDES PARADOX, LIAR'S PARADOX, SOCRATES' PARADOX

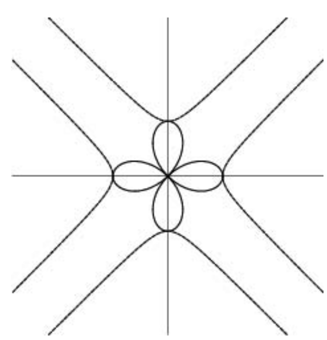
Epimorphism

A MORPHISM $f: Y \to X$ in a CATEGORY is an epimorphism if, for any two morphisms $u, v: X \to Z$, $uf = vf$ implies $u = v$.

See also CATEGORY, MORPHISM

Epispiral

A plane curve with polar equation



$$r = a\sec(n\theta).$$

There are n sections if n is ODD and $2n$ if n is EVEN.

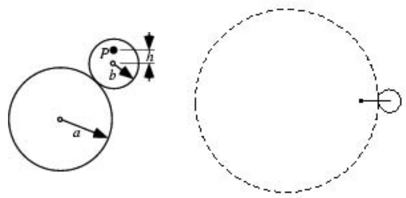
References

Lawrence, J. D. *A Catalog of Special Plane Curves.* New York: Dover, pp. 192–93, 1972.

Epispiral Inverse Curve

The INVERSE CURVE of the EPISPIRAL

$$r = a\sec(n\theta)$$



with INVERSION CENTER at the origin and inversion

radius k is the ROSE

$$r = \frac{k \cos(n\theta)}{a}.$$

See also EPISPIRAL, INVERSE CURVE, ROSE

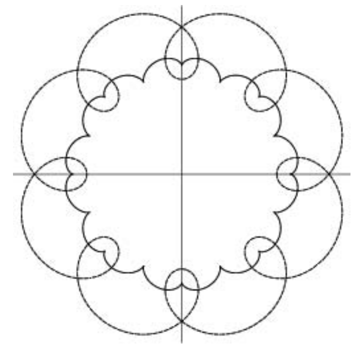
Epitrochoid

The ROULETTE traced by a point P attached to a CIRCLE of radius b rolling around the outside of a fixed CIRCLE of radius a. These curves were studied by Dürer (1525), Desargues (1640), Huygens (1679), Leibniz, Newton (1686), L'Hospital (1690), Jakob Bernoulli (1690), la Hire (1694), Johann Bernoulli (1695), Daniel Bernoulli (1725), Euler (1745, 1781). An epitrochoid appears in Dürer's work *Instruction in Measurement with Compasses and Straight Edge* (1525). He called epitrochoids SPIDER LINES because the lines he used to construct the curves looked like a spider.

The PARAMETRIC EQUATIONS for an epitrochoid are

$$x = (a+b)\cos t - h\cos\left(\frac{a+b}{b}t\right)$$

$$y = (a+b)\sin t - h\sin\left(\frac{a+b}{b}t\right),$$



where h is the distance from P to the center of the rolling CIRCLE. Special cases include the LIMAÇON with $a=b$, the CIRCLE with $a=0$, and the EPICYCLOID with $h=b$.

See also EPICYCLOID, HYPOTROCHOID, SPIROGRAPH, TROCHOID

References

Lawrence, J. D. *A Catalog of Special Plane Curves.* New York: Dover, pp. 168–70, 1972.

Epitrochoid Evolute

The PARAMETRIC EQUATIONS of the EVOLUTE of an EPITROCHOID specified by circle radii a and b with offset h are

$$x = \frac{ah(a+b)c_1(t)\cos t + bc_2(t)\cos\left[\frac{(a+b)t}{b}\right]}{b^3 + (a+b)h^2 - b(a+2b)h\cos\left(\frac{at}{b}\right)} \tag{1}$$

$$y = \frac{ah(a+b)c_1(t)\sin t + bc_2(t)\sin\left[\frac{(a+b)t}{b}\right]}{b^3 + (a+b)h^2 - b(a+2b)h\cos\left(\frac{at}{b}\right)}, \tag{2}$$

where

$$c_1(t) \equiv h - b\cos\left(\frac{at}{b}\right) \tag{3}$$

$$c_2(t) \equiv b - h\cos\left(\frac{at}{b}\right). \tag{4}$$

See also EPITROCHOID, EVOLUTE

Epsilon

In mathematics, a small POSITIVE INFINITESIMAL quantity, usually denoted ϵ or ε, whose LIMIT is usually taken as $\epsilon \to 0$.

The late mathematician P. Erdos also used the term "epsilons" to refer to children (Hoffman 1998, p. 4).

See also EPSILON CONJECTURE, WYNN'S EPSILON METHOD

Equal

Two quantities are said to be equal if they are, in some WELL DEFINED sense, equivalent. Equality of quantities a and b is written $a=b$. Equal is implemented in *Mathematica* as `Equal[`A, B, ...`]`, or $A==B==...$.

A symbol with three horizontal line segments ($\equiv$) resembling the equals sign is used to denote both equality by definition (e.g., $A\equiv B$ means A is DEFINED to be equal to B) and CONGRUENCE (e.g., $13\equiv 1 \pmod{12}$ means 13 divided by 12 leaves a REMAINDER of 1–a fact known to all readers of analog clocks).

See also CONGRUENCE, DEFINED, DIFFERENT, EQUAL BY DEFINITION, EQUALITY, EQUIVALENT, ISOMORPHISM, UNEQUAL

Equal by Definition

DEFINED

Equal Detour Point

The center of an outer SODDY CIRCLE. It has TRIANGLE CENTER FUNCTION

$$\alpha=1+\frac{2\Delta}{a(b+c-a)}=\sec(\tfrac{1}{2}A)\cos(\tfrac{1}{2}B)\cos(\tfrac{1}{2}C)+1.$$

Given a point Y not between A and B, a detour of length

$$|AY|+|YB|-|AB|$$

is made walking from A to B via Y, the point is of equal detour if the three detours from one side to another via Y are equal. If ABC has no ANGLE $>2\sin^{-1}(4/5)$, then the point given by the above TRILINEAR COORDINATES is the unique equal detour point. Otherwise, the ISOPERIMETRIC POINT is also equal detour.

Equal Incircles Theorem

INCIRCLE

Equal Parallelians Point

The point of intersection of the three LINE SEGMENTS, each parallel to one side of a TRIANGLE and touching the other two, such that all three segments are of the same length. The TRILINEAR COORDINATES are

$$bc(ca+ab-bc):ca(ab+bc-ca):ab(bc+ca-ab).$$

References

Kimberling, C. "Equal Parallelians Point." http://cedar.evansville.edu/~ck6/tcenters/recent/eqparal.html.

Equal-Area Projection

A MAP PROJECTION in which areas on a sphere, and the areas of any features contained on it, are mapped to the plane in such a way that two are related by a *constant* scaling factor. No projection can be both equal-area and CONFORMAL, and projections which are neither equal-area nor CONFORMAL are sometimes called APHYLACTIC (Snyder 1987, p. 4). Equal-area projections are also called EQUIVALENT, HOMOLOGRAPHIC, HOMALOGRAPHIC, AUTHALIC, or EQUIAREAL (Lee 1944; Snyder 1987, p. 4).

Equality

A mathematical statement of the equivalence of two quantities. The equality "A is equal to B" is written $A = B$.

See also EQUAL, FORMULA, INEQUALITY

Equally Likely Outcomes Distribution

Let there be a set S with N elements, each of them having the same probability. Then

$$P(S) = P\left(\bigcup_{i=1}^{N} E_i\right) = \sum_{i=1}^{N} P(E_i)$$

$$= P(E_i)\sum_{i=1}^{N} 1 = NP(E_i).$$

Using $P(S) \equiv 1$ gives

$$P(E_i) = \frac{1}{N}.$$

See also UNIFORM DISTRIBUTION

Equation

A mathematical expression stating that two or more quantities are the same as one another, also called an EQUALITY, FORMULA, or IDENTITY.

See also EQUALITY, FORMULA, IDENTITY, INEQUATION

Equiaffinity

An AREA-preserving AFFINITY. Equiaffinities include the CROSSED HYPERBOLIC ROTATION, ELLIPTIC ROTATION, HYPERBOLIC ROTATION, and PARABOLIC ROTATION.

Equiangular Polygon

A POLYGON whose vertex angles are equal (Williams 1979, p. 32).

Equichordal Point

A point $\mathbf{p}$ for which all the CHORDS of a curve C passing through $\mathbf{p}$ are of the same length. In other words, $\mathbf{p}$ is an equichordal point if, for every chord $[\mathbf{x}, \mathbf{y}]$ of length p of the curve C, $\mathbf{p}$ satisfies

$$|\mathbf{x} - \mathbf{p}| + |\mathbf{y} - \mathbf{p}| = p.$$

A function $r(\theta)$ satisfying

$$r(0) = p - r(\pi)$$

corresponds to a curve with equichordal point (0, 0) and chord length p defined by letting $r(\theta)$ be the polar equation of the half-curve for $0 \le \theta \le \pi$ and then superimposing the polar equation $r(\theta) - p$ over the same range. The curves illustrated above correspond

to polar equations OF THE FORM

$$r(\theta) = x + (\tfrac{1}{2} - x)\cos(2\theta)$$

for various values of x.

Although it long remained an outstanding problem (the EQUICHORDAL POINT PROBLEM), it is now known that a plane convex region can have two equichordal points.

Equichordal Point Problem

Is there a plane CONVEX SET having two distinct EQUICHORDAL POINTS? The problem was first proposed by Fujiwara (1916) and Blaschke *et al.* (1917), but long defied solution. Rogers went so far as to remark, "If you are interested in studying the problem, my first advice is: 'Don't'" (Croft *et al.* 1991, p. 9). This advice to the contrary, the problem was recently solved by Rychlik (1997).

Equidistributed Sequence

A sequence of REAL NUMBERS $\{x_n\}$ is equidistributed if the probability of finding x_n in any subinterval is proportional to the subinterval length.

Consider the distribution of the FRACTIONAL PARTS of nr in the intervals bounded by 0, $1/n$, $2/n$, ..., $(n-1)/n$, 1. In particular, the number of empty intervals for $n = 1, 2, ...,$ are given below for E, the EULER-MASCHERONI CONSTANT γ, the GOLDEN RATIO ϕ, and PI.

r	Sloane	# Empty Intervals for $n = 1, 2, ...,$
e	Sloane's A036412	0, 0, 0, 0, 1, 0, 0, 1, 1, 3, 1, 4, 4, 7, 5, ...
γ	Sloane's A046157	0, 0, 0, 1, 0, 0, 0, 1, 2, 2, 3, 0, 3, 5, 3, ...
ϕ	Sloane's A036414	0, 0, 0, 0, 0, 0, 1, 0, 2, 0, 1, 1, 0, 2, 2, ...
π	Sloane's A036416	0, 1, 1, 1, 1, 0, 0, 1, 2, 3, 4, 4, 5, 7, 7, ...

The values of n for which *no* bins are left blank are given in the following table.

r	Sloane	n with no empty intervals
e	Sloane's A036413	1, 2, 3, 4, 6, 7, 32, 35, 39, 71, 465, 536, 1001, ...
γ	Sloane's A046158	1, 2, 3, 5, 6, 7, 12, 19, 26, 97, 123, 149, 272, 395, ...
ϕ	Sloane's A036415	1, 2, 3, 4, 5, 6, 8, 10, 13, 16, 21, 34, 55, 89, 144, ...
π	Sloane's A036417	1, 6, 7, 106, 112, 113, 33102, 33215, ...

Steinhaus (1983) remarks that the highly uniform distribution of frac$(n\phi)$ has its roots in the form of the CONTINUED FRACTION for ϕ.

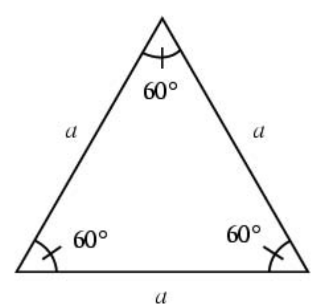
Equilateral Hyperbola

RECTANGULAR HYPERBOLA

Equilateral Polygon



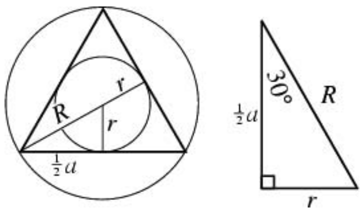
A POLYGON whose side are equal (Williams 1979, pp. 31–2).

See also EQUIANGULAR POLYGON, EQUILATERAL TRIANGLE, POLYGON, REGULAR POLYGON

References

Williams, R. *The Geometrical Foundation of Natural Structure: A Source Book of Design.* New York: Dover, 1979.

Equilateral Triangle



An equilateral triangle is a TRIANGLE with all three sides of equal length a. An equilateral triangle also has three equal 60° ANGLES.

The ALTITUDE h of an equilateral triangle is

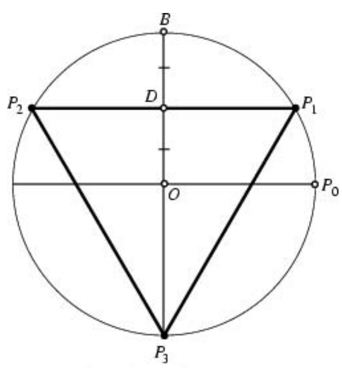
$$h = \tfrac{1}{2}\sqrt{3}a, \tag{1}$$

where a is the side length, so the AREA is

$$A = \tfrac{1}{2}ah = \tfrac{1}{4}\sqrt{3}a^2. \tag{2}$$

The INRADIUS r, CIRCUMRADIUS R, and AREA A can be computed directly from the formulas for a general REGULAR POLYGON with side length a and $n=3$ sides,

$$r=\tfrac{1}{2}a\cot\left(\frac{\pi}{3}\right)=\tfrac{1}{2}a\tan\left(\frac{\pi}{6}\right)=\tfrac{1}{6}\sqrt{3}a \quad (3)$$



$$R=\tfrac{1}{2}a\csc\left(\frac{\pi}{3}\right)=\tfrac{1}{2}a\sec\left(\frac{\pi}{6}\right)=\tfrac{1}{3}\sqrt{3}a \quad (4)$$

$$A=\tfrac{1}{4}na^2\cot\left(\frac{\pi}{3}\right)=\tfrac{1}{4}\sqrt{3}a^2. \quad (5)$$

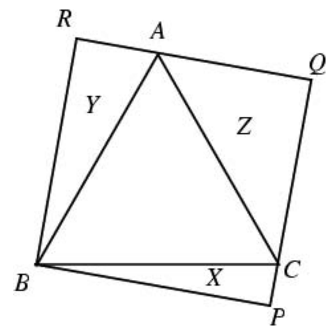
The AREAS of the INCIRCLE and CIRCUMCIRCLE are

$$A_r=\pi r^2=\tfrac{1}{12}\pi a^2 \quad (6)$$

$$A_R=\pi R^2=\tfrac{1}{3}\pi a^2. \quad (7)$$

equilateral triangle construction

GEOMETRIC CONSTRUCTION of an equilateral consists of drawing a diameter of a circle OP_O and then constructing its perpendicular bisector P_3OB. Bisect OB in point D, and extend the line P_1P_2 through D. The resulting figure $P_1P_2P_3$ is then an equilateral triangle. An equilateral triangle may also be constructed (although not using the usual Greek rules, which do *not* permit angle trisection) by TRISECTING all three ANGLES of any TRIANGLE (MORLEY'S THEOREM).

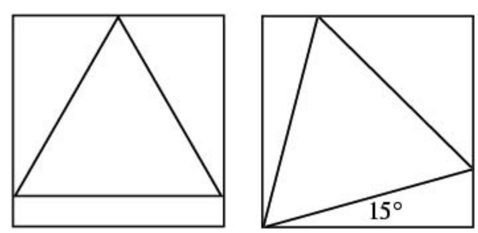


NAPOLEON'S THEOREM states that if three equilateral triangles are drawn on the LEGS of any TRIANGLE (either all drawn inwards or outwards) and the centers of these triangles are connected, the result is another equilateral triangle.

Given the distances of a point from the three corners of an equilateral triangle, a, b, and c, the length of a side s is given by

$$3(a^4+b^4+c^4+s^4)=(a^2+b^2+c^2+s^2)^2 \quad (8)$$

(Gardner 1977, pp. 56–7 and 63). There are infinitely many solutions for which a, b, and c are INTEGERS. In these cases, one of a, b, c, and s is DIVISIBLE by 3, one by 5, one by 7, and one by 8 (Guy 1994, p. 183).



Begin with an arbitrary TRIANGLE and find the EXCENTRAL TRIANGLE. Then find the EXCENTRAL TRIANGLE of that triangle, and so on. Then the resulting triangle approaches an equilateral triangle. The only RATIONAL TRIANGLE is the equilateral triangle (Conway and Guy 1996). A POLYHEDRON composed of only equilateral triangles is known as a DELTAHEDRON.

Let any RECTANGLE be circumscribed about an EQUILATERAL TRIANGLE. Then

$$X+Y=Z, \quad (9)$$

where X, Y, and Z are the AREAS of the triangles in the figure (Honsberger 1985).

The smallest equilateral triangle which can be inscribed in a UNIT SQUARE (left figure) has side length and area

$$s=1 \quad (10)$$

$$A=\tfrac{1}{4}\sqrt{3}\approx 0.4330. \quad (11)$$

The largest equilateral triangle which can be inscribed (right figure) is oriented at an angle of 15° and has side length and area

$$s=\sec(15^\circ)=\sqrt{6}-\sqrt{2} \quad (12)$$

$$A=2\sqrt{3}-3\approx 0.4641 \quad (13)$$

(Madachy 1979).

Equilateral Triangle Packing

TRIANGLE PACKING

Equilibrium Point

An equilibrium point in GAME THEORY is a set of strategies $\{\hat{x}_1, \ldots, \hat{x}_n\}$ such that the ith payoff function $K_i(\mathbf{x})$ is larger or equal for any other ith strategy, i.e.,

$$K_i(\hat{x}_1, \ldots, \hat{x}_n) \geq K_i(\hat{x}_1, \ldots, \hat{x}_{i-1}, x_i, \hat{x}_{i+1}, \ldots, \hat{x}_n).$$

NASH EQUILIBRIUM

Equilic Quadrilateral

A QUADRILATERAL in which a pair of opposite sides have the same length and are inclined at 60° to each other (or equivalently, satisfy $\langle A\rangle + \langle B\rangle = 120°$). Some interesting theorems hold for such quadrilaterals. Let $ABCD$ be an equilic quadrilateral with $AD = BC$ and $\langle A\rangle + \langle B\rangle = 120°$. Then

1. The MIDPOINTS P, Q, and R of the diagonals and the side CD always determine an EQUILATERAL TRIANGLE.
2. If EQUILATERAL TRIANGLE PCD is drawn outwardly on CD, then ΔPAB is also an EQUILATERAL TRIANGLE.
3. If EQUILATERAL TRIANGLES are drawn on AC, DC, and DB away from AB, then the three new VERTICES P, Q, and R are COLLINEAR.

See Honsberger (1985) for additional theorems.

Equinumerous

Let A and B be two classes of POSITIVE INTEGERS. Let $A(n)$ be the number of integers in A which are less than or equal to n, and let $B(n)$ be the number of integers in B which are less than or equal to n. Then if

$$A(n) \sim B(n),$$

A and B are said to be equinumerous.

The four classes of PRIMES $8k+1$, $8k+3$, $8k+5$, $8k+7$ are equinumerous. Similarly, since $8k+1$ and $8k+5$ are both of the form $4k+1$, and $8k+3$ and $8k+7$ are both OF THE FORM $4k+3$, $4k+1$ and $4k+3$ are also equinumerous.

Shanks, D. *Solved and Unsolved Problems in Number Theory, 4th ed.* New York: Chelsea, pp. 21–2 and 31–2, 1993.

Equipollent

Two statements in LOGIC are said to be equipollent if they are deducible from each other.

Two sets A and B are said to be equipollent IFF there is a one-to-one function (i.e., a BIJECTION) from A onto B (Moore 1982, p. 10; Rubin 1967, p. 67; Suppes 1972, p. 91).

The term equipotent is sometimes used instead of equipollent.

Suppes, P. *Axiomatic Set Theory.* New York: Dover, 1972.

Equipotent
EQUIPOLLENT

Equipotential Curve
A curve in 2-D on which the value of a function $f(x, y)$ is a constant. Other synonymous terms are ISARITHM and ISOPLETH. A plot of several equipotential curves is called a CONTOUR PLOT.

See also CONTOUR PLOT, LEMNISCATE

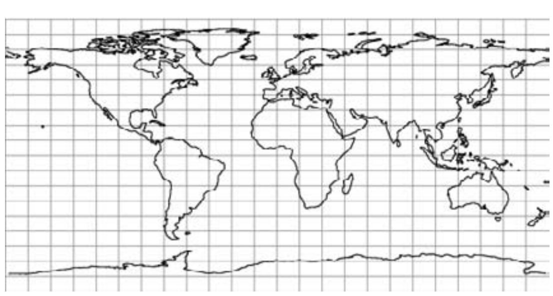
Equiproduct Point
A point, such as interior points of a disk, such that

$$(px)(py) = [\text{const}],$$

where p is the CHORD length.

See also EQUICHORDAL POINT, EQUIRECIPROCAL POINT

Equireciprocal Point
$\mathbf{p}$ is an equireciprocal point if, for every chord $[\mathbf{x}, \mathbf{y}]$ of a curve C, $\mathbf{p}$ satisfies



$$|\mathbf{x}-\mathbf{p}|^{-1} + |\mathbf{y}-\mathbf{p}|^{-1} = c$$

for some constant c. The FOCI of an ELLIPSE are equichordal points.

See also EQUICHORDAL POINT, EQUIPRODUCT POINT

Equirectangular Projection

A CYLINDRICAL EQUIDISTANT PROJECTION, also called a RECTANGULAR PROJECTION, PLANE CHART, PLATE CARRE, or UNPROJECTED MAP, in which the horizontal coordinate is the longitude and the vertical coordinate is the latitude, so the standard parallel is taken as $\phi_1 = 0$.

See also CYLINDRICAL EQUIDISTANT PROJECTION

Equiripple
A distribution of ERROR such that the ERROR remaining is always given approximately by the last term dropped.

Equitangential Curve
TRACTRIX

Equivalence
BICONDITIONAL, EQUIVALENT

Equivalence Class
An equivalence class is defined as a SUBSET OF THE FORM $\{x \in X : xRa\}$, where a is an element of X and the NOTATION "xRy" is used to mean that there is an EQUIVALENCE RELATION between x and y. It can be shown that any two equivalence classes are either equal or disjoint, hence the collection of equivalence classes forms a partition of X. For all $a, b \in X$, we have aRb IFF a and b belong to the same equivalence class.

A set of CLASS REPRESENTATIVES is a SUBSET of X which contains EXACTLY ONE element from each equivalence class.

For n a POSITIVE INTEGER, and a, b INTEGERS, consider the CONGRUENCE $a \equiv b \pmod{n}$, then the equivalence classes are the sets $\{\ldots, -2n, -n, 0, n, 2n, \ldots\}$, $\{\ldots, 1-2n, 1-n, 1, 1+n, 1+2n, \ldots\}$ etc. The standard CLASS REPRESENTATIVES are taken to be 0, 1, 2, ..., $n-1$.

See also CONGRUENCE, COSET

References
Shanks, D. *Solved and Unsolved Problems in Number Theory, 4th ed.* New York: Chelsea, pp. 56–7, 1993.

Equivalence Moves
REIDEMEISTER MOVES

Equivalence Problem
METRIC EQUIVALENCE PROBLEM

Equivalence Relation
An equivalence relation on a set X is a SUBSET of $X \times X$, i.e., a collection R of ordered pairs of elements of X, satisfying certain properties. Write "xRy" to mean (x, y) is an element of R, and we say "x is related to y," then the properties are

1. Reflexive: aRa for all $a \in X$,
2. Symmetric: aRb IMPLIES bRa for all a, $b \in X$
3. Transitive: aRb and bRc imply aRc for all a, b, $c \in X$,

where these three properties are completely independent. Other notations are often used to indicate a relation, e.g., $a \equiv b$ or $a \sim b$.

See also EQUIVALENCE CLASS, TEICHMÜLLER SPACE

References
Skiena, S. *Implementing Discrete Mathematics: Combinatorics and Graph Theory with Mathematica.* Reading, MA: Addison-Wesley, p. 18, 1990.

Equivalent

If $A \Rightarrow B$ and $B \Rightarrow A$ (i.e, $A \Rightarrow B \wedge B \Rightarrow A$, where $\Rightarrow$ denotes IMPLIES), then A and B are said to be equivalent, a relationship which is written symbolically as $A \equiv B$ (Carnap 1958, p. 8), $A \Leftrightarrow B$, or $A \rightleftharpoons B$. Equivalence is implemented in *Mathematica* as `Equal`[A, B, ...]. Binary equivalence has the following TRUTH TABLE (Carnap 1958, p. 10).

A	B	$A \equiv B$
T	T	T
T	F	F
F	T	F
F	F	T

Similarly, ternary equivalence has the following TRUTH TABLE.

A	B	C	$A \equiv B \equiv C$
T	T	T	T
T	T	F	F
T	F	T	F
T	F	F	F
F	T	T	F
F	T	F	F
F	F	T	F
F	F	F	T

The opposite of being equivalent is being NONEQUIVALENT.

Note that the symbol $\equiv$ is confusingly used in at least two other different contexts. If A and B are "equivalent by definition" (i.e., A is DEFINED to be B), this is written $A \equiv B$, and "a is CONGRUENT to b modulo m" is written $a \equiv b \pmod{m}$.

See also BICONDITIONAL, CONNECTIVE, DEFINED, IFF, IMPLIES, NONEQUIVALENT

References
Carnap, R. *Introduction to Symbolic Logic and Its Applications.* New York: Dover, p. 8, 1958.

Equivalent Matrix

Two matrices A and B are equal to each other, written $\mathsf{A} = \mathsf{B}$, if they have the same dimensions $m \times n$ and the same elements $a_{ij} = b_{ij}$ for $i = 1, ..., n$ and $j = 1, ..., m$.

Gradshteyn and Ryzhik (2000) call an $m \times n$ MATRIX A "equivalent" to another $m \times n$ MATRIX B IFF

$$\mathsf{B} = \mathsf{PAQ}$$

for P and Q any suitable nonsingular $m \times n$ and $n \times n$ MATRICES, respectively.

Equivalent Projection

EQUAL-AREA PROJECTION

Eratosthenes Sieve

An ALGORITHM for making tables of PRIMES. Sequentially write down the INTEGERS from 2 to the highest number n you wish to include in the table. Cross out all numbers > 2 which are divisible by 2 (every second number). Find the smallest remaining number > 2. It is 3. So cross out all numbers > 3 which are divisible by 3 (every third number). Find the smallest remaining number > 3. It is 5. So cross out all

numbers > 5 which are divisible by 5 (every fifth number).

Continue until you have crossed out all numbers divisible by $\lfloor \sqrt{n} \rfloor$, where $\lfloor x \rfloor$ is the FLOOR FUNCTION. The numbers remaining are PRIME. This procedure is illustrated in the above diagram which sieves up to 50, and therefore crosses out PRIMES up to $\lfloor \sqrt{50} \rfloor = 7$. If the procedure is then continued up to n, then the number of cross-outs gives the number of distinct PRIME FACTORS of each number.

Erdos Reciprocal Sum Constants

A-SEQUENCE, B_2-SEQUENCE, NONAVERAGING SEQUENCE

Erdos Squarefree Conjecture

The CENTRAL BINOMIAL COEFFICIENT $\binom{2n}{n}$ is never SQUAREFREE for $n > 4$. This was proved true for all sufficiently large n by SÁRKOZY'S THEOREM. Goetgheluck (1988) proved the CONJECTURE true for $4 < n \leq 2^{42205184}$ and Vardi (1991) for $4 < n < 2^{774840978}$. The conjecture was proved true in its entirety by Granville and Ramare (1996).

Erdos-Anning Theorem

If an infinite number of points in the PLANE are all separated by INTEGER distances, then all the points lie on a straight LINE.

Erdos-Heilbronn Conjecture

Erdos and Heilbronn (Erdos and Graham 1980) posed the problem of estimating from below the number of sums $a + b$ where $a \in A$ and $b \in B$ range over given sets $A, B \subseteq \mathbb{Z}/p\mathbb{Z}$ of residues modulo a prime p, so that $a \neq b$. Dias da Silva and Hamidoune (1994) gave a solution, and Alon *et al.* (1995) developed a polynomial method that allows one to handle restrictions of the type $f(a, b) \neq 0$, where f is a polynomial in two variables over $\mathbb{Z}/p\mathbb{Z}$.

Erdos-Kac Theorem

A deeper result than the HARDY-RAMANUJAN THEOREM. Let $N(x, a, b)$ be the number of INTEGERS in $[3, x]$ such that inequality

$$a \leq \frac{\omega(n) - \ln \ln n}{\sqrt{\ln \ln n}} \leq b$$

holds, where $\omega(n)$ is the number of DISTINCT PRIME FACTORS of n. Then

$$\lim_{x\to\infty} N(x, a, b) = \frac{(x + o(x))}{\sqrt{2\pi}} \int_a^b e^{-t^2/2}\, dt.$$

The theorem is discussed in Kac (1959).

Erdos-Mordell Theorem

If O is any point inside a TRIANGLE ΔABC, and P, Q, and R are the feet of the perpendiculars from O upon the respective sides BC, CA, and AB, then

$$OA + OB + OC \geq 2(OP + OQ + OR).$$

Oppenheim (1961) and Mordell (1962) also showed that

$$OA \times OB \times OC \geq (OQ + OR)(OR + OP)(OP + OQ).$$

Erdos-Moser Equation

The DIOPHANTINE EQUATION

$$\sum_{j=1}^{m-1} j^n = m^n.$$

Erdos conjectured that there is no solution to this equation other than the trivial solution $1^1 + 2^1 = 3^1$, although this remains unproved (Guy 1994, pp. 153–54). Moser (1953) proved that there is no solution for $m < 10^{10^6}$, and Butske *et al.* (1999) extended this to $m < 10^{9.3\times 10^6}$, or more specifically, $m < 1.485 \times 10^{9321155}$.

Erdos-Selfridge Function

The Erdos-Selfridge function $g(k)$ is defined as the least integer bigger than $k+1$ such that the LEAST PRIME FACTOR of $\binom{g(k)}{k}$ exceeds k (Ecklund *et al.* 1974, Erdos*et al.* 1993). The best lower bound known is

$$g(k) \geq \exp\left(c\sqrt{\frac{[\ln k]^3}{\ln \ln k}}\right)$$

(Granville and Ramare 1996). Scheidler and Williams (1992) tabulated $g(k)$ up to $k = 140$, and Lukes *et al.* (1997) tabulated $g(k)$ for $135 \leq k \leq 200$. The values for $n = 2, 3, \ldots$ are 4, 7, 7, 23, 62, 143, 44, 159, 46, 47, 174, 2239, ... (Sloane's A046105).

Erf

The "error function" encountered in integrating the GAUSSIAN DISTRIBUTION (which is a normalized form of the GAUSSIAN FUNCTION),

$$\operatorname{erf}(z) \equiv \frac{2}{\sqrt{\pi}} \int_0^z e^{-t^2}\, dt \quad (1)$$

$$= 1 - \operatorname{erfc}(z) \quad (2)$$

$$= \pi^{-1/2} \gamma(\tfrac{1}{2}, z^2), \quad (3)$$

where ERFC is the complementary error function and $\gamma(x, a)$ is the incomplete GAMMA FUNCTION. It can also be defined as a MACLAURIN SERIES

$$\operatorname{erf}(z) = \frac{2}{\sqrt{\pi}} \sum_{n=0}^{\infty} \frac{(-1)^n z^{2n+1}}{n!(2n+1)}. \quad (4)$$

Erf has the values

$$\operatorname{erf}(0) = 0 \quad (5)$$

$$\operatorname{erf}(\infty) = 1. \quad (6)$$

It is an ODD FUNCTION

$$\operatorname{erf}(-z) = -\operatorname{erf}(z), \quad (7)$$

and satisfies

$$\operatorname{erf}(z) + \operatorname{erfc}(z) = 1. \quad (8)$$

Erf may be expressed in terms of a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND M as

$$\operatorname{erf}(z) = \frac{2z}{\sqrt{\pi}} M(\tfrac{1}{2}, \tfrac{3}{2}, -z^2) = \frac{2z}{\sqrt{\pi}} e^{-z^2} M(1, \tfrac{3}{2}, z^2). \quad (9)$$

Erf is bounded by

$$\frac{1}{x+\sqrt{x^2+2}} < e^{x^2} \int_x^\infty e^{-t^2}\,dt \leq \frac{1}{x+\sqrt{x^2+\frac{4}{\pi}}}. \quad (10)$$

Its DERIVATIVE is

$$\frac{d^n}{dz^n}\,\mathrm{erf}(z) = (-1)^{n-1}\frac{2}{\sqrt{\pi}}\,H_{n-1}(z)e^{-z^2}, \quad (11)$$

where H_n is a HERMITE POLYNOMIAL. The first DERIVATIVE is

$$\frac{d}{dz}\,\mathrm{erf}(z) = \frac{2}{\sqrt{\pi}}\,e^{-z^2}, \quad (12)$$

and the integral is

$$\int \mathrm{erf}(z)\,dz = z\,\mathrm{erf}(z) + \frac{e^{-z^2}}{\sqrt{\pi}}. \quad (13)$$

For $x \ll 1$, erf may be computed from

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}}\int_0^x e^{-t^2}\,dt \quad (14)$$

$$= \frac{2}{\sqrt{\pi}}\int_0^x \sum_{k=0}^\infty \frac{(-t^2)^k}{k!}\,dt$$

$$= \frac{2}{\sqrt{\pi}}\int_0^x \sum_{k=0}^\infty \frac{(-1)^k t^{2k}}{k!}\,dt$$

$$= \frac{2}{\sqrt{\pi}}\sum_{k=0}^\infty \frac{x^{2k+1}(-1)^k}{k!(2k+1)} \quad (15)$$

$$= \frac{2}{\sqrt{\pi}}\left(x - \tfrac{1}{3}x^3 + \tfrac{1}{10}x^5 - \tfrac{1}{42}x^7 + \tfrac{1}{216}x^9 - \tfrac{1}{1320}x^{11} + \ldots\right) \quad (16)$$

$$= \frac{2}{\sqrt{\pi}}\,e^{-x^2}x\left[1 + \frac{2x^2}{1\cdot 3} + \frac{(2x^2)^2}{1\cdot 3\cdot 5} + \ldots\right] \quad (17)$$

(Acton 1990). For $x \gg 1$,

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}}\left(\int_0^\infty e^{-t^2}\,dt - \int_x^\infty e^{-t^2}\,dt\right)$$

$$= 1 - \frac{2}{\sqrt{\pi}}\int_x^\infty e^{-t^2}\,dt. \quad (18)$$

Using INTEGRATION BY PARTS gives

$$\int_x^\infty e^{-t^2}\,dt = -\frac{1}{2}\int_x^\infty \frac{1}{t}\,d(e^{-t^2})$$

$$= -\frac{1}{2}\left[\frac{e^{-t^2}}{t}\right]_x^\infty - \frac{1}{2}\int_x^\infty \frac{e^{-t^2}\,dt}{t^2}$$

$$= \frac{e^{-x^2}}{2x} + \frac{1}{4}\int_x^\infty \frac{1}{t^3}\,d(e^{-t^2})$$

$$= \frac{e^{-x^2}}{2x} - \frac{e^{-x^2}}{4x^3} - \ldots, \quad (19)$$

so

$$\mathrm{erf}(x) = 1 - \frac{e^{-x^2}}{\sqrt{\pi}x}\left(1 - \frac{1}{2x^2} - \ldots\right) \quad (20)$$

and continuing the procedure gives the ASYMPTOTIC SERIES

$$\mathrm{erf}(x) = 1 - \frac{e^{-x^2}}{\sqrt{\pi}} \times \left(x^{-1} - \tfrac{1}{2}x^{-3} + \tfrac{3}{4}x^{-5} - \tfrac{15}{8}x^{-7} + \tfrac{105}{16}x^{-9} + \ldots\right). \quad (21)$$

Ramanujan rediscovered the CONTINUED FRACTION formula

$$\int_0^a e^{-t^2}\,dt = \tfrac{1}{2}\sqrt{\pi}\,\mathrm{erf}\,a$$

$$= \tfrac{1}{2}\sqrt{\pi} - \frac{e^{-a^2}}{2a+}\,\frac{1}{a+}\,\frac{2}{2a+}\,\frac{3}{a+}\,\frac{4}{2a+\ldots}, \quad (22)$$

first stated by Laplace and proved by Jacobi (Watson 1928; Hardy 1999, pp. 8–).

A COMPLEX generalization of erf x is defined as

$$w(z) = e^{-z^2}\,\mathrm{erfc}(-iz) \quad (23)$$

$$= e^{-z^2}\left(1 + \frac{2i}{\sqrt{\pi}} + \frac{2i}{\sqrt{\pi}}\int_0^z e^{t^2}dt\right) \quad (24)$$

$$= \frac{i}{\pi}\int_{-\infty}^\infty \frac{e^{-t^2}dt}{z-t} = \frac{2iz}{\pi}\int_0^\infty \frac{e^{-t^2}dt}{z-t}. \quad (25)$$

Erfc

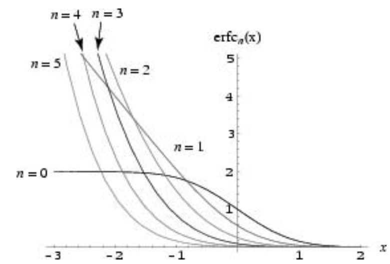
The "complementary error function" defined by

$$\operatorname{erfc}(x) \equiv 1 - \operatorname{erf}(x) \tag{1}$$

$$= \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt \tag{2}$$

$$= \sqrt{\pi}\gamma(\tfrac{1}{2}, z^2), \tag{3}$$

where γ is the incomplete GAMMA FUNCTION. It has the values



$$\operatorname{erfc}(0) = 1 \tag{4}$$

$$\lim_{x\to\infty} \operatorname{erfc}(x) = 0 \tag{5}$$

$$\operatorname{erfc}(-x) = 2 - \operatorname{erfc}(x) \tag{6}$$

$$\int_0^\infty \operatorname{erfc}(x)\, dx = \frac{1}{\sqrt{\pi}} \tag{7}$$

$$\int_0^\infty \operatorname{erfc}^2(x)\, dx = \frac{2-\sqrt{2}}{\sqrt{\pi}}. \tag{8}$$

A generalization is obtained from the ERFC DIFFERENTIAL EQUATION

$$\frac{d^2y}{dz^2} + 2z\frac{dy}{dz} - 2ny = 0 \tag{9}$$

(Abramowitz and Stegun 1972, p. 299; Zwillinger 1997, p. 122). The general solution is then

$$y = A \operatorname{erfc}_n(z) + B \operatorname{erfc}_n(-z), \tag{10}$$

where $\operatorname{erfc}_n(z)$ is the repeated erfc integral. For integral $n \geq 1$,

$$\operatorname{erfc}_n(z) = \underbrace{\int \cdots \int}_{n} \operatorname{erfc}(z)\, dz \tag{11}$$

$$= \frac{2}{\sqrt{2}} \int_z^\infty \frac{(t-z)^n}{n!} e^{-t^2}\, dt \tag{12}$$

$$= 2^{-n} e^{-z^2} \left[\frac{{}_1F_1(\frac{1}{2}(n+1);\ \frac{1}{2};\ z^2)}{\Gamma(1+\frac{1}{2}n)} - \frac{2z\, {}_1F_1(1+\frac{1}{2}n;\ \frac{3}{2};\ z^2)}{\Gamma(\frac{1}{2}(n+1))} \right] \tag{13}$$

(Abramowitz and Stegun 1972), where ${}_1F_1(a;\ b;\ z)$ is a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND and $\Gamma(z)$ is a GAMMA FUNCTION. The first few values, extended by the definition for $n = -1$ and 0, are given by

$$\operatorname{erfc}_{-1}(z) = \frac{2}{\sqrt{\pi}} e^{-z^2} \tag{14}$$

$$\operatorname{erfc}_0(z) = \operatorname{erfc}(z) \tag{15}$$

$$\operatorname{erfc}_1(z) = \frac{e^{-z^2}}{\sqrt{\pi}} - z \operatorname{erfc}(z) \tag{16}$$

$$\mathrm{erfc}_2(z) = \frac{1}{4}\left[(1+2z^2)\,\mathrm{erfc}(z) - \frac{2ze^{-z^2}}{\sqrt{\pi}}\right]. \qquad (17)$$

Erfi

$$\mathrm{erfi}(z) \equiv -i\,\mathrm{erf}(iz).$$

A ASYMPTOTIC SERIES for the erfi function is given by

$$\mathrm{erfi}(x) \sim \pi^{-1/2} x^{-1} e^{x^2}.$$

See also DAWSON'S INTEGRAL, ERF, ERFC

Ergodic Measure

An ENDOMORPHISM is called ergodic if it is true that $T^{-1}A = A$ IMPLIES $m(A) = 0$ or 1, where $T^{-1}A = \{x \in X : T(x) \in A\}$. Examples of ergodic endomorphisms include the MAP $X \to 2x$ mod 1 on the unit interval with LEBESGUE MEASURE, certain AUTOMORPHISMS of the TORUS, and "Bernoulli shifts" (and more generally "Markov shifts").

Given a MAP T and a SIGMA ALGEBRA, there may be many ergodic measures. If there is only one ergodic measure, then T is called uniquely ergodic. An example of a uniquely ergodic transformation is the MAP $x \mapsto x + a$ mod 1 on the unit interval when a is irrational. Here, the unique ergodic measure is LEBESGUE MEASURE.

Ergodic Theory

Ergodic theory can be described as the statistical and qualitative behavior of measurable group and semigroup actions on MEASURE SPACES. The GROUP is most commonly N, R, R+, and Z.

Ergodic theory had its origins in the work of Boltzmann in statistical mechanics problems where time-

and space-distribution averages are equal. Steinhaus (1983, pp. 237–39) gives a practical application to ergodic theory to keeping one's feet dry (when walking along a shoreline without having to constantly turn one's head to anticipate incoming waves. The mathematical origins of ergodic theory are due to von Neumann, Birkhoff, and Koopman in the 1930s. It has since grown to be a huge subject and has applications not only to statistical mechanics, but also to NUMBER THEORY, DIFFERENTIAL GEOMETRY, FUNCTIONAL ANALYSIS, etc. There are also many internal problems (e.g., ergodic theory being applied to ergodic theory) which are interesting.

Ergodic Transformation

A transformation which has only trivial invariant SUBSETS is said to be ergodic.

Erlang Distribution

Given a POISSON DISTRIBUTION with a rate of change λ, the DISTRIBUTION FUNCTION $D(x)$ giving the waiting times until the hth Poisson event is

$$D(x) = 1 - \frac{\Gamma(h,\ x\lambda)}{\Gamma(h)} \tag{1}$$

for $x \in [0,\ \infty)$, where $\Gamma(x)$ is a complete GAMMA FUNCTION, and $\Gamma(a,\ x)$ an INCOMPLETE GAMMA FUNCTION. With h explicitly an integer, this distribution is known as the Erlang distribution, and has probability function

$$P(x) = \frac{\lambda(\lambda x)^{h-1}}{(h-1)!}\, e^{-\lambda x}. \tag{2}$$

It is closely related to the GAMMA DISTRIBUTION, which is obtained by letting $\alpha \equiv h$ (not necessarily an integer) and defining $\theta \equiv 1/\lambda$. When $h = 1$, it simplifies to the EXPONENTIAL DISTRIBUTION.

See also EXPONENTIAL DISTRIBUTION, GAMMA DISTRIBUTION

Erlanger Program

A program initiated by F. Klein in an 1872 lecture to describe geometric structures in terms of their AUTOMORPHISM GROUPS.

Error

The difference between a quantity and its estimated or measured quantity.

See also ABSOLUTE ERROR, PERCENTAGE ERROR, RELATIVE ERROR

Error Curve

GAUSSIAN FUNCTION

Error Function

ERF, ERFC

Error Function Distribution

A NORMAL DISTRIBUTION with MEAN 0,

$$P(x) = \frac{h}{\sqrt{\pi}} e^{-h^2x^2}. \tag{1}$$

The CHARACTERISTIC FUNCTION is

$$\phi(t) = e^{-t^2/(4h^2)}. \tag{2}$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = 0 \tag{3}$$

$$\sigma^2 = \frac{1}{2h^2} \tag{4}$$

$$\gamma_1 = 0 \tag{5}$$

$$\gamma_2 = 0. \tag{6}$$

The CUMULANTS are

$$\kappa_1 = 0 \tag{7}$$

$$\kappa_2 = \frac{1}{2h^2} \tag{8}$$

$$\kappa_n = 0 \tag{9}$$

for $n \geq 3$.

Error Propagation

Given a FORMULA $y = f(x)$ with an ABSOLUTE ERROR in x of dx, the ABSOLUTE ERROR is dy. The RELATIVE ERROR is dy/y. If $x = f(u, v)$, then

$$x_i - \bar{x} = (u_i - \bar{u})\frac{\partial x}{\partial u} + (v_i - \bar{v})\frac{\partial x}{\partial v} + \ldots, \tag{1}$$

where $\bar{x}$ denotes the MEAN, so

$$\sigma_x^2 \equiv \frac{1}{N-1}\sum_{i=1}^{N}(x_i - \bar{x})^2$$

$$= \frac{1}{N-1}\sum_{i=1}^{N}\left[(u_i - \bar{u})^2\left(\frac{\partial x}{\partial u}\right)^2 + (v_i - \bar{v})^2\left(\frac{\partial x}{\partial v}\right)^2\right.$$

$$\left. + 2(u_i - \bar{u})(v_i - \bar{v})\left(\frac{\partial x}{\partial u}\right)\left(\frac{\partial x}{\partial v}\right) + \ldots\right]. \tag{2}$$

The definitions of VARIANCE and COVARIANCE then give

$$\sigma_u^2 \equiv \frac{1}{N-1}\sum_{i=1}^{N}(u_i - \bar{u})^2 \tag{3}$$

$$\sigma_v^2 \equiv \frac{1}{N-1}\sum_{i=1}^{N}(v_i - \bar{v})^2 \tag{4}$$

$$\sigma_{uv} \equiv \frac{1}{N-1}\sum_{i=1}^{N}(u_i - \bar{u})(v_i - \bar{v}) \tag{5}$$

(where $\sigma_{ii} \equiv \sigma_i^2$), so

$$\sigma_x^2 = \sigma_u^2\left(\frac{\partial x}{\partial u}\right)^2 + \sigma_v^2\left(\frac{\partial x}{\partial v}\right)^2 + 2\sigma_{uv}\left(\frac{\partial x}{\partial u}\right)\left(\frac{\partial x}{\partial v}\right) + \ldots. \tag{6}$$

If u and v are uncorrelated, then $\sigma_{uv} = 0$ so

$$\sigma_x^2 = \sigma_u^2\left(\frac{\partial x}{\partial u}\right)^2 + \sigma_v^2\left(\frac{\partial x}{\partial v}\right)^2. \tag{7}$$

Now consider addition of quantities with errors. For $x = au \pm bv$, $\partial x/\partial u = a$ and $\partial x/\partial v = \pm b$, so

$$\sigma_x^2 = a^2\sigma_u^2 + b^2\sigma_v^2 \pm 2ab\sigma_{uv}. \qquad (8)$$

For division of quantities with $x = \pm au/v$, $\partial x/\partial u = \pm a/v$ and $\partial x/\partial v = \mp au/v^2$, so

$$\sigma_x^2 = \frac{a^2}{v^2}\sigma_u^2 + \frac{a^2u^2}{v^4}\sigma_v^2 - 2\frac{a}{v}\frac{au}{v^2}\sigma_{uv}. \qquad (9)$$

$$\left(\frac{\sigma_x}{x}\right)^2 = \frac{a^2}{v^2}\frac{v^2}{a^2u^2}\sigma_u^2 + \frac{a^2u^2}{v^4}\frac{v^2}{a^2u^2} - 2\left(\frac{a}{v}\right)\left(\frac{au}{v^2}\right)\sigma_{uv}$$

$$= \left(\frac{\sigma_u}{u}\right)^2 + \left(\frac{\sigma_v}{v}\right)^2 - 2\left(\frac{\sigma_{uv}}{u}\right)\left(\frac{\sigma_{uv}}{v}\right). \qquad (10)$$

For exponentiation of quantities with

$$x = a^{\pm bu} = (e^{\ln a})^{\pm bu} = e^{\pm b(\ln a)u}, \qquad (11)$$

$$\frac{\partial x}{\partial u} = \pm b(\ln a)e^{\pm b \ln au} = \pm b(\ln a)x, \qquad (12)$$

so

$$\sigma_x = \sigma_u b(\ln a)x \qquad (13)$$

$$\frac{\sigma_x}{x} = b \ln a\sigma_u. \qquad (14)$$

If $a = e$, then

$$\frac{\sigma_x}{x} = b\sigma_u. \qquad (15)$$

For LOGARITHMS of quantities with $x = a\ln(\pm bu)$, $\partial x/\partial u = a(\pm b)/(\pm bu) = a/u$, so

$$\sigma_x^2 = \sigma_u^2\left(\frac{a^2}{u^2}\right) \qquad (16)$$

$$\sigma_x = a\frac{\sigma_u}{u}. \qquad (17)$$

For multiplication with $x = \pm auv$, $\partial x/\partial u = \pm av$ and $\partial x/\partial v = \pm au$, so

$$\sigma_x^2 = a^2v^2\sigma_u^2 + a^2u^2\sigma_v^2 + 2a^2uv\sigma_{uv} \qquad (18)$$

$$\left(\frac{\sigma_x}{x}\right)^2 = \frac{a^2v^2}{a^2u^2v^2}\sigma_u^2 + \frac{a^2u^2}{a^2u^2v^2}\sigma_v^2 + \frac{2a^2uv}{a^2u^2v^2}\sigma_{uv}$$

$$= \left(\frac{\sigma_u}{u}\right)^2 + \left(\frac{\sigma_v}{v}\right)^2 + 2\left(\frac{\sigma_{uv}}{u}\right)\left(\frac{\sigma_{uv}}{v}\right). \qquad (19)$$

For POWERS, with $x = au^{\pm b}$, $\partial x/\partial u = \pm abu^{\pm b-1} = \pm bx/u$, so

$$\sigma_x^2 = \sigma_u^2\frac{b^2x^2}{u^2} \qquad (20)$$

$$\frac{\sigma_x}{x} = b\frac{\sigma_u}{u}. \qquad (21)$$

Error-Correcting Code

An error-correcting code is an algorithm for expressing a sequence of numbers such that any errors which are introduced can be detected and corrected (within certain limitations) based on the remaining numbers. The study of error-correcting codes and the associated mathematics is known as CODING THEORY.

Error detection is much simpler than error correction, and one or more "check" digits are commonly embedded in credit card numbers in order to detect mistakes. Early space probes like Mariner used a type of error-correcting code called a block code, and more recent space probes use convolution codes. Error-correcting codes are also used in CD players, high speed modems, and cellular phones. Modems use error detection when they compute CHECKSUMS, which are sums of the digits in a given transmission modulo some number. The ISBN used to identify books also incorporates a check DIGIT.

A powerful check for 13 DIGIT numbers consists of the following. Write the number as a string of DIGITS $a_1, a_2, a_3 \ldots a_{13}$. Take $a_1 + a_3 + \cdots + a_{13}$ and double. Now add the number of DIGITS in ODD positions which are > 4 to this number. Now add $a_2 + a_4 + \cdots + a_{12}$. The check number is then the number required to bring the last DIGIT to 0. This scheme detects all single DIGIT errors and all TRANSPOSITIONS of adjacent DIGITS except 0 and 9.

Let $A(n, d)$ denote the maximal number of n (0,1)-vectors having the property that any two of the set differ in at least d places. The corresponding vectors can correct $[(d-1)/2]$ errors. $A(n, d, w)$ is the number of $A(n, d)$s with precisely w 1s (Sloane and Plouffe 1995). Since it is not possible for n-vectors to differ in $d > n$ places and since n-vectors which differ in all n places partition into disparate sets of two,

$$A(n,\ d)=\begin{cases}1 & n<d\\ 2 & n=d.\end{cases}$$

Values of $A(n,\ d)$ can be found by labeling the 2^n (0,1)-n-vectors, finding all unordered pairs $(a_i,\ a_j)$ of n-vectors which differ from each other in at least d places, forming a GRAPH from these unordered pairs, and then finding the CLIQUE NUMBER of this graph. Unfortunately, finding the size of a clique for a given GRAPH is an NP-COMPLETE PROBLEM.

Essential Supremum

The functions f and g have the same essential supremum

The essential supremum is the proper generalization to MEASURABLE FUNCTIONS of the MAXIMUM. The technical difference is that the values of a function on a set of MEASURE ZERO don't affect the essential supremum.

Given a MEASURABLE FUNCTION $f: X \to \mathbb{R}$, where X is a MEASURE SPACE with measure μ, the essential supremum is the smallest number α such that

$$\mu(\{x \text{ such that } f(x) > \alpha\}$$

has MEASURE ZERO. If no such number exists, as in the case of $f(x) = 1/x$ on $(0, 1)$, then the essential supremum is ∞.

The essential supremum of the absolute value of a function $|f|$ is usually denoted $\|f\|_\infty$, and this serves as the norm for L-INFINITY-SPACE.

See also L-INFINITY-SPACE, L_P-SPACE, L2-SPACE, MEASURE, MEASURABLE FUNCTION, MEASURE SPACE

Estimate

An estimate is an educated guess for an unknown quantity or outcome based on known information. The making of estimates is an important part of statistics, since care is needed to provide as accurate an estimate as possible using as little input data as possible. Often, an estimate for the uncertainty ΔE of an estimate E can also be determined statistically. A rule that tells how to calculate an estimate based on the measurements contained in a sample is called an ESTIMATOR.

See also BIAS (ESTIMATOR), ERROR, ESTIMATOR

References

Iyanaga, S. and Kawada, Y. (Eds.). "Statistical Estimation and Statistical Hypothesis Testing." Appendix A, Table 23 in *Encyclopedic Dictionary of Mathematics.* Cambridge, MA: MIT Press, pp. 1486–489, 1980.

Estimator

An estimator is a rule that tells how to calculate an ESTIMATE based on the measurements contained in a sample. For example, the "sample MEAN" AVERAGE $\bar{x}$ is an estimator for the population MEAN μ.

The mean square error of an estimator $\tilde{\theta}$ is defined by

$$\text{MSE} \equiv \left\langle (\tilde{\theta} - \theta)^2 \right\rangle.$$

Let B be the BIAS, then

$$\text{MSE} = \left\langle [(\tilde{\theta} - \langle \tilde{\theta} \rangle) + B(\tilde{\theta})]^2 \right\rangle$$

$$= \left\langle (\tilde{\theta} - \langle \tilde{\theta} \rangle)^2 \right\rangle + B^2(\tilde{\theta}) \equiv V(\tilde{\theta}) + B^2(\tilde{\theta}),$$

where V is the estimator VARIANCE.

See also BIAS (ESTIMATOR), ERROR, ESTIMATE, K-STATISTIC, UNBIASED ESTIMATOR

Eta Function

DEDEKIND ETA FUNCTION, DIRICHLET ETA FUNCTION, JACOBI THETA FUNCTIONS

Et-Function

A function which arises in FRACTIONAL CALCULUS.

$$E_t(\nu, a) = \frac{1}{\Gamma(\nu)} e^{at} \int_0^t x^{\nu-1} e^{-ax}\, dx = t^\nu e^{at} \gamma(\nu, at), \tag{1}$$

where $\gamma(a, \xi)$ is the incomplete GAMMA FUNCTION and $\Gamma(z)$ the complete GAMMA FUNCTION. The E_t function satisfies the RECURRENCE RELATION

$$E_t(\nu, a) = aE_t(\nu + 1, a) + \frac{t^\nu}{\Gamma(\nu + 1)}. \tag{2}$$

A special value is

$$E_t(0, a) = e^{at}. \tag{3}$$

Euclid Number

The nth Euclid number is defined by

$$E_n \equiv 1 + \prod_{i=1}^{n} p_i = 1 + p_n\#,$$

where p_i is the ith PRIME and $p_n\#$ is the PRIMORIAL. The first few E_n are 3, 7, 31, 211, 2311, 30031, 510511, 9699691, 223092871, 6469693231, ... (Sloane's A006862; Tietze 1965, p. 19).

The largest factors of E_n for $n = 1, 2, ...$ are 3, 7, 31, 211, 2311, 509, 277, 27953, ... (Sloane's A002585). The n of the first few PRIME Euclid numbers E_n are 1, 2, 3, 4, 5, 11, 75, 171, 172, 384, 457, 616, 643, ... (Sloane's A014545), and the largest known Euclid number is E_{4413}. It is not known if there are an INFINITE number of PRIME Euclid numbers (Guy 1994, Ribenboim 1996).

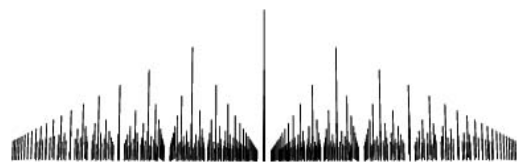
Euclid's Axioms

EUCLID'S POSTULATES



Euclid's Elements

ELEMENTS

Euclid's Fifth Postulate

EUCLID'S POSTULATES

Euclid's Orchard

An array of "trees" of unit height located at integer-coordinate points in a POINT LATTICE. When viewed from a corner along the line $y = x$ in normal perspective, a QUADRANT of Euclid's orchard turns into the modified DIRICHLET FUNCTION (Gosper).

See also DIRICHLET FUNCTION, GREATEST COMMON DIVISOR, ORCHARD-PLANTING PROBLEM

Euclid's Postulates

1. A straight LINE SEGMENT can be drawn joining any two points.
2. Any straight LINE SEGMENT can be extended indefinitely in a straight LINE.
3. Given any straight LINE SEGMENT, a CIRCLE can be drawn having the segment as RADIUS and one endpoint as center.
4. All RIGHT ANGLES are congruent.
5. If two lines are drawn which intersect a third in such a way that the sum of the inner angles on one side is less than two RIGHT ANGLES, then the two lines inevitably must intersect each other on that side if extended far enough. This postulate is equivalent to what is known as the PARALLEL POSTULATE.

Euclid's fifth postulate cannot be proven as a theorem, although this was attempted by many people. Euclid himself used only the first four postulates (for the first 28 propositions of the ELEMENTS, but was forced to invoke the PARALLEL POSTULATE on the 29th. In 1823, Janos Bolyai and Nicolai Lobachevsky independently realized that entirely self-consistent "NON-EUCLIDEAN GEOMETRIES" could be created in which the parallel postulate *did not hold.* (Gauss had also discovered but suppressed the existence of non-Euclidean geometries.)

Euclid's Principle

EUCLID'S THEOREMS

Euclid's Theorems

A theorem sometimes called "Euclid's First Theorem" or EUCLID'S PRINCIPLE states that if p is a PRIME and $p|ab$, then $p|a$ or $p|b$ (where | means DIVIDES). A COROLLARY is that $p|a^n \Rightarrow p|a$ (Conway and Guy 1996). The FUNDAMENTAL THEOREM OF ARITHMETIC is another COROLLARY (Hardy and Wright 1979).

Euclid's Second Theorem states that the number of PRIMES is INFINITE. This theorem, also called the INFINITUDE OF PRIMES theorem, was proved by Euclid in Proposition IX.20 of the ELEMENTS (Tietze 1965, pp. 7–). Ribenboim (1989) gives nine (and a half) proofs of this theorem. Euclid's elegant proof proceeds as follows. Given a finite sequence of consecutive PRIMES 2, 3, 5, ..., p, the number

$$N = 2 \cdot 3 \cdot 5 \cdots p + 1, \quad (1)$$

known as the ith EUCLID NUMBER when $p = p_i$ is the ith PRIME, is either a new PRIME or the product of PRIMES. If N is a PRIME, then it must be greater than the previous PRIMES, since one plus the product of PRIMES must be greater than each PRIME composing the product. Now, if N is a product of PRIMES, then at least one of the PRIMES must be greater than p. This can be shown as follows.

If N is COMPOSITE and has no prime factors greater than p, then one of its factors (say F) must be one of the PRIMES in the sequence, 2, 3, 5, ..., p. It therefore DIVIDES the product $2 \cdot 3 \cdot 5 \cdots p$. However, since it is a factor of N, it also DIVIDES N. But a number which DIVIDES two numbers a and $b < a$ also DIVIDES their difference $a - b$, so F must also divide

$$N - (2 \cdot 3 \cdot 5 \cdots p) = (2 \cdot 3 \cdot 5 \cdots p + 1) - (2 \cdot 3 \cdot 5 \cdots p) = 1. \quad (2)$$

However, in order to divide 1, F must be 1, which is contrary to the assumption that it is a PRIME in the sequence 2, 3, 5, ... It therefore follows that if N is composite, it has at least one factor greater than p. Since N is either a PRIME greater than p or contains a prime factor greater than p, a PRIME larger than the largest in the finite sequence can always be found, so there are an infinite number of PRIMES. Hardy (1967) remarks that this proof is "as fresh and significant as when it was discovered" so that "two thousand years have not written a wrinkle" on it.

A similar argument shows that $p! \pm 1$ and

$$1 \cdot 3 \cdot 5 \cdot 7 \cdots p + 1 \quad (3)$$

must be either PRIME or be divisible by a PRIME $> p$. Kummer used a variation of this proof, which is also a proof by contradiction. It assumes that there exist only a finite number of PRIMES $N = p_1, p_2, ..., p_r$. Now consider $N - 1$. It must be a product of PRIMES, so it has a PRIME divisor p_i in common with N. Therefore, $p_i | N - (N-1) = 1$ which is nonsense, so we have proved the initial assumption is wrong by contradiction.

It is also true that there are runs of COMPOSITE NUMBERS which are arbitrarily long. This can be seen by defining

$$n \equiv j! = \prod_{i=1}^{j} i, \quad (4)$$

where $j!$ is a FACTORIAL. Then the $j-1$ consecutive numbers $n+2$, $n+3$, ..., $n+j$ are COMPOSITE, since

$$n + 2 = (1 \cdot 2 \cdots j) + 2 = 2(1 \cdot 3 \cdot 4 \cdots n + 1) \quad (5)$$

$$n + 3 = (1 \cdot 2 \cdots j) + 3 = 3(1 \cdot 2 \cdot 4 \cdot 5 \cdots n + 1) \quad (6)$$

$$n + j = (1 \cdot 2 \cdots j) + j = j[1 \cdot 2 \cdots (j-1) + 1]. \quad (7)$$

Guy (1981, 1988) points out that while $p_1 p_2 \cdots p_n + 1$ is not necessarily PRIME, letting q be the next PRIME after $p_1 p_2 \cdots p_n + 1$, the number $q - p_1 p_2 \cdots p_n + 1$ is almost always a PRIME, although it has not been proven that this must *always* be the case.

Euclidean Algorithm

An ALGORITHM for finding the GREATEST COMMON DIVISOR of two numbers a and b, also called Euclid's algorithm. The algorithm can also be defined for more general RINGS than just the integers $\mathbb{Z}$. There are even PRINCIPAL RINGS which are not EUCLIDEAN but where one can define the equivalent of the Euclidean algorithm. The algorithm for rational numbers was given in Book VII of Euclid's *Elements*, and the algorithm for reals appeared in Book X, and is the earliest example of an INTEGER RELATION algorithm (Ferguson *et al.* 1999).

The Euclidean algorithm is an example of a P-PROBLEM whose time complexity is bounded by a quadratic function of the length of the input values (Banach and Shallit). Let $a = bq + r$, then find a number u which DIVIDES both a and b (so that $a = su$ and $b = tu$), then u also DIVIDES r since

$$r = a - bq = su - qtu = (s - qt)u. \tag{1}$$

Similarly, find a number v which DIVIDES b and r (so that $b = s'v$ and $r = t'v$), then v DIVIDES a since

$$a = bq + r = s'vq + t'v = (s'q + t')v. \tag{2}$$

Therefore, every common DIVISOR of a and b is a common DIVISOR of b and r, so the procedure can be iterated as follows.

$$q_1 = \left\lfloor \frac{a}{b} \right\rfloor \quad a = bq_1 + r_1 \quad r_1 = a - bq_1 \tag{3}$$

$$q_2 = \left\lfloor \frac{b}{r_1} \right\rfloor \quad b = q_2 r_1 + r_2 \quad r_2 = b - q_2 r_1 \tag{4}$$

$$q_3 = \left\lfloor \frac{r_1}{r_2} \right\rfloor \quad r_1 = q_3 r_2 + r_3 \quad r_3 = r_1 - q_3 r_2 \tag{5}$$

$$q_4 = \left\lfloor \frac{r_2}{r_3} \right\rfloor \quad r_2 = q_4 r_3 + r_4 \quad r_4 = r_2 - q_4 r_3 \tag{6}$$

$$q_n = \left\lfloor \frac{r_{n-2}}{r_{n-1}} \right\rfloor \quad r_{n-2} = q_n r_{n-1} + r_n \quad r_n = r_{n-2} - q_n r_{n-1} \tag{7}$$

$$q_{n+1} = \left\lfloor \frac{r_{n-1}}{r_n} \right\rfloor \quad r_{n-1} = q_{n+1} r_n + 0 \quad r_n = r_{n-1}/q_{n+1}. \tag{8}$$

For integers, the algorithm terminates when q_{n+1} divides r_{n-1} exactly, at which point r_n corresponds to the GREATEST COMMON DIVISOR of a and b, $\mathrm{GCD}(a, b) = r_n$. For real numbers, the algorithm yields either an exact relation or an infinite sequence of approximate relations (Ferguson *et al.* 1999).

Lamé showed that the number of steps needed to arrive at the GREATEST COMMON DIVISOR for two numbers less than n is

$$\text{steps} \le \frac{\log_{10} n}{\log_{10} \phi} + \frac{\log_{10} \sqrt{5}}{\log_{10} \phi} \tag{9}$$

where ϕ is the GOLDEN MEAN, or ≤ 5 times the number of digits in the smaller number (Wells 1986, p. 59). Numerically, Lamé's expression evaluates to

$$\text{steps} \le 4.785 \log_{10} n + 1.6723. \tag{10}$$

As shown by LAMÉ'S THEOREM, the worst case occurs when the ALGORITHM is applied to two consecutive FIBONACCI NUMBERS. Heilbronn showed that the average number of steps is $12 \ln 2/\pi^2 \log_{10} n = 0.843 \log_{10} n$ for all pairs (n, b) with $b < n$. Kronecker showed that the shortest application of the ALGORITHM uses least absolute remainders. The QUOTIENTS obtained are distributed as shown in the following table (Wagon 1991).

Quotient	%
1	41.5
2	17.0
3	9.3

For details, see Uspensky and Heaslet (1939) or Knuth (1973). Let $T(m, n)$ be the number of divisions required to compute $\mathrm{GCD}(m, n)$ using the Euclidean algorithm, and define $T(m, 0) = 0$ if $m \ge 0$. Then the function $T(m, n)$ is given by the RECURRENCE RELATION

$$T(m, n) = \begin{cases} 1 + T(n, m \bmod n) & \text{for } m \ge n \\ 1 + T(n, m) & \text{for } m < n. \end{cases} \tag{11}$$

Tabulating this function for $0 \le m < n$ gives

$$\begin{array}{cccccc} 0 \\ 0 & 1 \\ 0 & 1 & 2 \\ 0 & 1 & 1 & 2 \\ 0 & 1 & 2 & 3 & 2 \\ 0 & 1 & 1 & 1 & 2 & 2 \end{array}$$

(Sloane's A051010). The maximum numbers of steps for a given $n = 1, 2, 3, \ldots$ are 1, 2, 2, 3, 2, 3, 4, 3, 3, 4, 4, 5, ... (Sloane's A034883).

Define the functions

$$T(n) = \frac{1}{n} \sum_{0 \le m < n} T(m, n) \tag{12}$$

$$\tau(n) = \frac{1}{\phi(n)} \sum_{0 < m < n_{\mathrm{GCD}(m,\, n)=1}} T(m, n) \tag{13}$$

$$A(N) = \frac{1}{N^2} \sum_{1 \le m < N_{1 \le n \le N}} T(m, n), \tag{14}$$

where $\phi(n)$ is the TOTIENT FUNCTION, $T(n)$ is the average number of divisions when n is fixed and m chosen at random, $\tau(n)$ is the average number of divisions when n is fixed and m is a random number coprime to n, and $A(N)$ is the average number of divisions when m and n are both chosen at random in $[1, N]$. The first few values of $T(n)$ are 0, 1/2, 1, 1, 8/5, 7/6, 13/7, 7/4, ... (Sloane's A051011 and A051012).

Norton (1990) showed that

$$T(n) = \frac{12 \ln 2}{\pi^2}\left[\ln n - \sum_{d|n} \frac{\Lambda(d)}{d}\right] + C + \frac{1}{n}\sum_{d|n} \phi(d)\mathcal{O}(d^{-1/6+\epsilon}), \quad (15)$$

where $\Lambda(d)$ is the VON MANGOLDT FUNCTION and C is PORTER'S CONSTANT. Porter (1975) showed that

$$\tau(n) = \frac{12 \ln 2}{\pi^2} \ln n + C + \mathcal{O}(n^{-1/6} + \epsilon), \quad (16)$$

and Norton (1990) proved that

$$A(N) = \frac{12 \ln 2}{\pi^2}\left[\ln N - \tfrac{1}{2} + \frac{6}{\pi^2}\zeta'(2)\right] + C - \tfrac{1}{2} + \mathcal{O}(N^{-1/6+\epsilon}), \quad (17)$$

where $\zeta'(z)$ is the derivative of the RIEMANN ZETA FUNCTION.

There exist 21 QUADRATIC FIELDS in which there is a Euclidean algorithm (Inkeri 1947, Barnes and Swinnerton-Dyer 1952).

Although various attempts were made to generalize the algorithm to find INTEGER RELATIONS between $n \geq 3$ variables, none were successful until the discovery of the FERGUSON-FORCADE ALGORITHM (Ferguson *et al.* 1999). Several other INTEGER RELATION algorithms have now been discovered.

Euclidean Norm

L2-NORM

Euclidean Number

A Euclidean number is a number which can be obtained by repeatedly solving the QUADRATIC EQUATION. Euclidean numbers, together with the RATIONAL NUMBERS, can be constructed using classical GEOMETRIC CONSTRUCTIONS. However, the cases for which the values of the TRIGONOMETRIC FUNCTIONS SINE, COSINE, TANGENT, etc., can be written in closed form involving square roots of REAL NUMBERS are much more restricted.

Euclidean Plane

The 2-D EUCLIDEAN SPACE denoted $\mathbb{R}^2$.

See also COMPLEX PLANE, EUCLIDEAN SPACE

Euclidean Ring

A RING without zero divisors in which an integer norm and an associated division algorithm (i.e., a EUCLIDEAN ALGORITHM) can be defined. For signed integers, the usual norm is the ABSOLUTE VALUE and the division algorithm gives the ordinary QUOTIENT and REMAINDER. For polynomials, the norm is the degree.

Important examples of Euclidean rings (besides $\mathbb{Z}$) are the GAUSSIAN INTEGERS and $\mathbb{C}[x]$, the RING of polynomials with complex coefficients. All Euclidean rings are also PRINCIPAL RINGS.

See also EUCLIDEAN ALGORITHM, PRINCIPAL RING, RING

References

Wilson, J. C. "A Principle Ring that is Not a Euclidean Ring." *Math. Mag.* 34–8, 1973.

Euclidean Space

Euclidean n-space is the SPACE of all n-tuples of REAL NUMBERS, $(x_1, x_2, ..., x_n)$ and is denoted $\mathbb{R}^n$. It is sometimes also called Cartesian space. $\mathbb{R}^n$ is a VECTOR SPACE and has LEBESGUE COVERING DIMENSION n. Elements of $\mathbb{R}^n$ are called n-VECTORS. $\mathbb{R}^1 = \mathbb{R}$ is the set of REAL NUMBERS (i.e., the REAL LINE), and $\mathbb{R}^2$ is called the EUCLIDEAN PLANE. In Euclidean space, COVARIANT and CONTRAVARIANT quantities are equivalent so $\vec{e}^j = \vec{e}_j$.

Euclid-Mullin Sequence

The sequence of numbers obtained by letting $a_i = 2$, and defining

$$a_n = 1\text{pf}\left(1 + \prod_{k=1}^{n-1} a_k\right)$$

where lpf(n) is the LEAST PRIME FACTOR. The first few terms are 2, 3, 7, 43, 13, 53, 5, 6221671, 38709183810571, 139, ... (Sloane's A000945). Only 43 terms of the sequence are known; the 44th requires factoring a composite 180-digit number.

See also EUCLID NUMBER, LEAST PRIME FACTOR

Eudoxus's Kampyle

KAMPYLE OF EUDOXUS

Euler Angles

According to EULER'S ROTATION THEOREM, any ROTATION may be described using three ANGLES. If the ROTATIONS are written in terms of ROTATION MATRICES B, C, and D, then a general ROTATION A can be written as

$$\mathsf{A} = \mathsf{BCD}. \tag{1}$$

The three angles giving the three rotation matrices are called Euler angles. There are several conventions for Euler angles, depending on the axes about which the rotations are carried out. Write the MATRIX A as

$$\mathsf{A} \equiv \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}. \tag{2}$$

The so-called "x-convention," illustrated above, is the most common definition. In this convention, the rotation given by Euler angles (ϕ, θ, ψ)), where the first rotation is by an angle ϕ about the z-AXIS, the second is by an angle $\theta \in [0, \pi]$ about the x-AXIS, and the third is by an angle ψ about the z-AXIS (again). Note, however, that several notational conventions for the angles are in common use. Goldstein (1960, pp. 145–48) and Landau and Lifschitz (1976) use (ϕ, θ, ψ), Tuma (1974) says (ψ, θ, ϕ) is used in aeronautical engineering in the analysis of space vehicles (but claims that (ϕ, θ, ψ) is used in the analysis of gyroscopic motion), while Bate *et al.* (1971) use (Ω, i, ω). Goldstein remarks that continental authors usually use (ψ, θ, ϕ), and warns that left-handed coordinate systems are also in occasional use (Osgood 1937, Margenau and Murphy 1956–4). Here, the notation (ϕ, θ, ψ) is used, a convention also followed by *Mathematica*'s `RotateMatrix3D[`*phi*, *theta*, *psi*`]` in the *Mathematica* add-on package ``Geometry`Rotations` `` (which can be loaded with the command ``<<Geometry` ``) and `RotateShape[`*g*, *phi*, *theta*, *psi*`]` in the *Mathematica* add-on package ``Graphics`Shapes` `` (which can be loaded with the command ``<<Graphics` ``) commands. In the x-convention, the component rotations are then given by

$$\mathsf{D} \equiv \begin{bmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{3}$$

$$\mathsf{C} \equiv \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & \sin\theta \\ 0 & -\sin\theta & \cos\theta \end{bmatrix} \tag{4}$$

$$\mathsf{B} \equiv \begin{bmatrix} \cos\psi & \sin\psi & 0 \\ -\sin\psi & \cos\psi & 0 \\ 0 & 0 & 1 \end{bmatrix}, \tag{5}$$

so

$$a_{11} = \cos\psi\cos\phi - \cos\theta\sin\phi\sin\psi$$
$$a_{12} = \cos\psi\sin\phi + \cos\theta\cos\phi\sin\psi$$
$$a_{13} = \sin\psi\sin\theta$$
$$a_{21} = -\sin\psi\cos\phi - \cos\theta\sin\phi\cos\psi$$
$$a_{22} = -\sin\psi\sin\phi + \cos\theta\cos\phi\cos\psi$$
$$a_{23} = \cos\psi\sin\theta$$
$$a_{31} = \sin\theta\sin\phi$$
$$a_{32} = -\sin\theta\cos\phi$$
$$a_{33} = \cos\theta$$

To obtain the components of the ANGULAR VELOCITY ω in the body axes, note that for a MATRIX

$$\mathsf{A} \equiv [\mathbf{A}_1 \quad \mathbf{A}_2 \quad \mathbf{A}_3], \tag{6}$$

it is true that

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} \omega_x \\ \omega_y \\ \omega_z \end{bmatrix} = \begin{bmatrix} a_{11}\omega_x + a_{12}\omega_y + a_{13}\omega_z \\ a_{21}\omega_x + a_{22}\omega_y + a_{23}\omega_z \\ a_{31}\omega_x + a_{32}\omega_y + a_{33}\omega_z \end{bmatrix} \tag{7}$$

$$= \mathbf{A}_1\omega_x + \mathbf{A}_2\omega_y + \mathbf{A}_3\omega_z. \tag{8}$$

Now, ω_z corresponds to rotation about the ϕ axis, so look at the ω_z component of $\mathsf{A}\boldsymbol{\omega}$,

$$\boldsymbol{\omega}_\phi = \mathbf{A}_1\omega_z = \begin{bmatrix} \sin\psi\sin\theta \\ \cos\psi\sin\theta \\ \cos\theta \end{bmatrix}\dot\phi. \tag{9}$$

The line of nodes corresponds to a rotation by θ about the ξ-axis, so look at the ω_ξ component of $\mathsf{B}\boldsymbol{\omega}$,

$$\boldsymbol{\omega}_\theta = \mathbf{B}_1\omega_\xi = \mathbf{B}_1\dot\theta = \begin{bmatrix} \cos\psi \\ -\sin\psi \\ 0 \end{bmatrix}\dot\theta. \tag{10}$$

Similarly, to find rotation by ψ about the remaining axis, look at the ω_ψ component of $\mathsf{B}\boldsymbol{\omega}$,

$$\boldsymbol{\omega}_\psi = \mathbf{B}_3\omega_\psi = \mathbf{B}_3\psi = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}\dot\psi. \tag{11}$$

Combining the pieces gives

$$\boldsymbol{\omega} = \begin{bmatrix} \sin\psi\sin\theta\,\dot\phi + \cos\psi\dot\theta \\ \cos\psi\sin\theta\,\dot\phi - \sin\psi\dot\theta \\ \cos\theta\dot\phi + \dot\psi. \end{bmatrix} \tag{12}$$

For more details, see Goldstein (1980, p. 176) and Landau and Lifschitz (1976, p. 111).

The x-convention Euler angles are given in terms of the CAYLEY-KLEIN PARAMETERS by

$$\phi = -2i\ln\left[\pm\frac{\alpha^{1/2}\gamma^{1/4}}{\beta^{1/4}(1+\beta\gamma)^{1/4}}\right],\ -2i\ln\left[\pm\frac{i\alpha^{1/2}\gamma^{1/4}}{\beta^{1/4}(1+\beta\gamma)^{1/4}}\right] \tag{13}$$

$$\psi = -2i\ln\left[\pm\frac{\alpha^{1/2}\beta^{1/4}}{\gamma^{1/4}(1+\beta\gamma)^{1/4}}\right],\ -2i\ln\left[\pm\frac{i\alpha^{1/2}\beta^{1/4}}{\gamma^{1/4}(1+\beta\gamma)^{1/4}}\right] \tag{14}$$

$$\theta = \pm 2\cos^{-1}\left(\pm\sqrt{1+\beta\gamma}\right). \tag{15}$$

In the "y-convention,"

$$\phi_x \equiv \phi_y + \tfrac{1}{2}\pi \tag{16}$$

$$\psi_x \equiv \psi_y - \tfrac{1}{2}\pi. \tag{17}$$

Therefore,

$$\sin\phi_x = \cos\phi_y \tag{18}$$

$$\cos\phi_x = -\sin\phi_y \tag{19}$$

$$\sin\psi_x = -\cos\psi_y \tag{20}$$

$$\cos\psi_x = \sin\psi_y, \tag{21}$$

giving rotation matrices

$$\mathsf{D} \equiv \begin{bmatrix} -\sin\phi & \cos\phi & 0 \\ -\cos\phi & -\sin\phi & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{22}$$

$$\mathsf{C} \equiv \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & \sin\theta \\ 0 & -\sin\theta & \cos\theta \end{bmatrix} \tag{23}$$

$$\mathsf{B} \equiv \begin{bmatrix} \sin\psi & -\cos\psi & 0 \\ \cos\psi & \sin\psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{24}$$

and A is given by

$$a_{11} = -\sin\psi\sin\phi + \cos\theta\cos\phi\cos\psi$$
$$a_{12} = \sin\psi\cos\phi + \cos\theta\sin\phi\cos\psi$$
$$a_{13} = -\cos\psi\sin\theta$$
$$a_{21} = -\cos\psi\sin\phi - \cos\theta\cos\phi\sin\psi$$
$$a_{22} = \cos\psi\cos\phi - \cos\theta\sin\phi\sin\psi$$
$$a_{23} = \sin\psi\sin\theta$$
$$a_{31} = \sin\theta\cos\phi$$
$$a_{32} = \sin\theta\sin\phi$$
$$a_{33} = \cos\theta.$$

In the "*xyz*" (pitch-roll-yaw) convention, θ is pitch, ψ is roll, and ϕ is yaw.

$$D \equiv \begin{bmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (25)$$

$$C \equiv \begin{bmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & 0 \\ \sin\theta & 0 & \cos\theta \end{bmatrix} \quad (26)$$

$$B \equiv \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\psi & \sin\psi \\ 0 & -\sin\psi & \cos\psi \end{bmatrix} \quad (27)$$

and A is given by

$$\begin{aligned} a_{11} &= \cos\theta\cos\phi \\ a_{12} &= \cos\theta\sin\phi \\ a_{13} &= -\sin\theta \\ a_{21} &= \sin\psi\sin\theta\cos\phi - \cos\psi\sin\phi \\ a_{22} &= \sin\psi\sin\theta\sin\phi + \cos\psi\cos\phi \\ a_{23} &= \cos\theta\sin\psi \\ a_{31} &= \cos\psi\sin\theta\cos\phi + \sin\psi\sin\phi \\ a_{32} &= \cos\psi\sin\theta\sin\phi - \sin\psi\cos\phi \\ a_{33} &= \cos\theta\cos\psi. \end{aligned}$$

Varshalovich (1988, pp. 21–3) use the notation (α, β, γ) or $(\alpha', \beta', \gamma')$ to denote the Euler angles, and give three different angle conventions, none of which corresponds to the x-convention.

A set of parameters sometimes used instead of angles are the EULER PARAMETERS e_0, e_1, e_2 and e_3, defined by

$$e_0 \equiv \cos\left(\frac{\phi}{2}\right) \quad (28)$$

$$\mathbf{e} \equiv \begin{bmatrix} e_1 \\ e_2 \\ e_3 \end{bmatrix} = \hat{\mathbf{n}} \sin\left(\frac{\phi}{2}\right). \quad (29)$$

Using EULER PARAMETERS (which are QUATERNIONS), an arbitrary ROTATION MATRIX can be described by

$$\begin{aligned} a_{11} &= e_0^2 + e_1^2 - e_2^2 - e_3^2 \\ a_{12} &= 2(e_1 e_2 + e_0 e_3) \\ a_{13} &= 2(e_1 e_3 - e_0 e_2) \\ a_{21} &= 2(e_1 e_2 - e_0 e_3) \\ a_{22} &= e_0^2 - e_1^2 + e_2^2 - e_3^2 \\ a_{23} &= 2(e_2 e_3 + e_0 e_1) \\ a_{31} &= 2(e_1 e_3 + e_0 e_2) \\ a_{32} &= 2(e_2 e_3 - e_0 e_1) \\ a_{33} &= e_0^2 - e_1^2 - e_2^2 + e_3^2 \end{aligned}$$

(Goldstein 1960, p. 153).

If the coordinates of two pairs of n points $\mathbf{x}_i$ and $\mathbf{x}'_i$ are known, one rotated with respect to the other, then the Euler rotation matrix can be obtained in a straightforward manner using LEAST SQUARES FITTING. Write the points as arrays of vectors, so

$$[\mathbf{x}'_i \cdots \mathbf{x}'_n] = A[\mathbf{x}_1 \cdots \mathbf{x}_n]. \quad (30)$$

Writing the arrays of vectors as matrices gives

$$X' = AX \quad (31)$$

$$X'X^T = AXX^T, \quad (32)$$

and solving for A gives

$$A = X'X^T(XX^T)^{-1}. \quad (33)$$

However, we want the angles θ, ϕ, and ψ, not their combinations contained in the MATRIX A. Therefore, write the 3×3 MATRIX

$$A = \begin{bmatrix} f_1(\theta, \phi, \psi) & f_2(\theta, \phi, \psi) & f_3(\theta, \phi, \psi) \\ f_4(\theta, \phi, \psi) & f_5(\theta, \phi, \psi) & f_6(\theta, \phi, \psi) \\ f_7(\theta, \phi, \psi) & f_7(\theta, \phi, \psi) & f_9(\theta, \phi, \psi) \end{bmatrix} \quad (34)$$

as a 1×9 VECTOR

$$\mathbf{f} = \begin{bmatrix} f_1(\theta, \phi, \psi) \\ \vdots \\ f_9(\theta, \phi, \psi) \end{bmatrix}. \quad (35)$$

Now set up the matrices

$$\begin{bmatrix} \left.\frac{\partial f_1}{\partial\theta}\right|_{\theta_i, \phi_i, \psi_i} & \left.\frac{\partial f_1}{\partial\phi}\right|_{\theta_i, \phi_i, \psi_i} & \left.\frac{\partial f_1}{\partial\psi}\right|_{\theta_i, \phi_i, \psi_i} \\ \vdots & \vdots & \vdots \\ \left.\frac{\partial f_9}{\partial\theta}\right|_{\theta_i, \phi_i, \psi_i} & \left.\frac{\partial f_9}{\partial\phi}\right|_{\theta_i, \phi_i, \psi_i} & \left.\frac{\partial f_9}{\partial\psi}\right|_{\theta_i, \phi_i, \psi_i} \end{bmatrix} \begin{bmatrix} d\theta \\ d\phi \\ d\psi \end{bmatrix} = d\mathbf{f}. \quad (36)$$

Using NONLINEAR LEAST SQUARES FITTING then gives solutions which converge to (θ, ϕ, ψ).

Euler Brick

A RECTANGULAR PARALLELEPIPED ("BRICK") with integer edges $a > b > c$ and face diagonals d_{ij} given by

$$d_{ab} = \sqrt{a^2 + b^2} \quad (1)$$

$$d_{ac} = \sqrt{a^2 + c^2} \quad (2)$$

$$d_{bc} = \sqrt{b^2 + c^2}. \quad (3)$$

The problem is also called the brick problem, diagonals problem, perfect box problem, perfect cuboid problem, or rational cuboid problem.

The smallest solution with integer edges and face diagonals has sides $(a, b, c) = (240, 117, 44)$ and face DIAGONALS $d_{ab} = 267$, $d_{ac} = 244$, and $d_{bc} = 125$, and was discovered by Halcke (1719; Dickson 1952, pp. 497–00). Interest in this problem was high during the 18th century, and Saunderson (1740) found a parametric solution, while Euler (1770, 1772) found at least two parametric solutions. Kraitchik gave 257 cuboids with the ODD edge less than 1 million (Guy 1994, p. 174). F. Helenius has compiled a list of the 5003 smallest (measured by the longest edge) Euler bricks. The first few are (240, 117, 44), (275, 252, 240), (693, 480, 140), (720, 132, 85), (792, 231, 160), ... (Sloane's A031173, A031174, and A031175). Parametric solutions for Euler bricks are also known.

No solution is known to the more general problem in which the oblique SPACE DIAGONAL

$$d_{abc} = \sqrt{a^2 + b^2 + c^2} \quad (4)$$

is also an INTEGER. If such a brick exists, the smallest side must be at least 1,281,000,000 (R. Rathbun 1996). Such a solution is equivalent to solving the DIOPHANTINE EQUATIONS

$$A^2 + B^2 = C^2 \quad (5)$$

$$A^2 + D^2 = E^2 \quad (6)$$

$$B^2 + D^2 = F^2 \quad (7)$$

$$B^2 + E^2 = G^2. \quad (8)$$

A solution with integral SPACE DIAGONAL and two out of three face diagonals is $a = 672$, $b = 153$, and $c = 104$, giving $d_{ab} = 3\sqrt{52777}$, $d_{ac} = 680$, $d_{bc} = 185$, and $d_{abc} = 697$, which was known to Euler. A solution giving integral space and face diagonals with only a single nonintegral EDGE is $a = 18720$, $b = \sqrt{211773121}$, and $c = 7800$, giving $d_{ab} = 23711$, $d_{ac} = 20280$, $d_{bc} = 16511$, and $d_{abc} = 24961$.

Euler Chain

A CHAIN whose EDGES consist of all graph EDGES.

Euler Characteristic

Let a closed surface have GENUS g. Then the POLYHEDRAL FORMULA generalizes to the POINCARÉ FORMULA

$$\chi \equiv V - E + F = \chi(g), \quad (1)$$

where

$$\chi(g) = 2 - 2g \quad (2)$$

is the Euler characteristic, sometimes also known as the EULER-POINCARÉ CHARACTERISTIC. The POLYHEDRAL FORMULA corresponds to the special case $g = 0$. The only compact closed surfaces with Euler characteristic 0 are the KLEIN BOTTLE and TORUS (Dodson and Parker 1997, p. 125).

In terms of the INTEGRAL CURVATURE of the surface K,

$$\iint K\, da = 2\pi\chi. \quad (3)$$

The Euler characteristic is sometimes also called the EULER NUMBER. It can also be expressed as

$$\chi = p_0 - p_1 + p_2, \quad (4)$$

where p_i is the ith BETTI NUMBER of the space.

Euler Constant

e, EULER-MASCHERONI CONSTANT, MACLAURIN-CAUCHY THEOREM

Euler Curvature Formula

The curvature of a surface satisfies

$$\kappa = \kappa_1 \cos^2\theta + \kappa_2 \sin^2\theta,$$

where κ is the normal CURVATURE in a direction making an ANGLE θ with the first principal direction and κ_1 and κ_2 are the PRINCIPAL CURVATURES.

See also PRINCIPAL CURVATURES

Euler Differential Equation

The general nonhomogeneous differential equation is given by

$$x^2 \frac{d^2y}{dx^2} + \alpha x \frac{dy}{dx} + \beta y = S(x), \tag{1}$$

and the homogeneous equation is

$$x^2 y'' + \alpha x y' + \beta y = 0 \tag{2}$$

$$y'' + \frac{\alpha}{x} y' + \frac{\beta}{x^2} y = 0. \tag{3}$$

Now attempt to convert the equation from

$$y'' + p(x)y' + q(x)y = 0 \tag{4}$$

to one with constant COEFFICIENTS

$$\frac{d^2y}{dz^2} + A \frac{dy}{dz} + By = 0 \tag{5}$$

by using the standard transformation for linear SECOND-ORDER ORDINARY DIFFERENTIAL EQUATIONS. Comparing (3) and (5), the functions $p(x)$ and $q(x)$ are

$$p(x) \equiv \frac{\alpha}{x} = \alpha x^{-1} \tag{6}$$

$$q(x) \equiv \frac{\beta}{x^2} = \beta x^{-2}. \tag{7}$$

Let $B \equiv \beta$ and define

$$z \equiv B^{-1/2} \int \sqrt{q(x)}\, dx = \beta^{-1/2} \int \sqrt{\beta x^{-2}}\, dx$$
$$= \int x^{-1}\, dx = \ln x. \tag{8}$$

Then A is given by

$$A \equiv \frac{q'(x) + 2p(x)q(x)}{2[q(x)]^{3/2}} B^{1/2}$$
$$= \frac{-2\beta x^{-3} + 2(\alpha x^{-1})(\beta x^{-2})}{2(\beta x^{-2})^{3/2}} \beta^{1/2}$$
$$= \alpha - 1, \tag{9}$$

which is a constant. Therefore, the equation becomes a second-order ODE with constant COEFFICIENTS

$$\frac{d^2y}{dz^2} + (\alpha - 1)\frac{dy}{dz} + \beta y = 0. \tag{10}$$

Define

$$r_1 \equiv \tfrac{1}{2}\left(-A + \sqrt{A^2 - 4B}\right)$$
$$= \tfrac{1}{2}\left[1 - \alpha + \sqrt{(\alpha-1)^2 - 4\beta}\right] \tag{11}$$

$$r_2 \equiv \tfrac{1}{2}\left(-A - \sqrt{A^2 - 4B}\right)$$
$$= \tfrac{1}{2}\left[1 - \alpha - \sqrt{(\alpha-1)^2 - 4\beta}\right] \tag{12}$$

and

$$a \equiv \tfrac{1}{2}(1 - \alpha) \tag{13}$$

$$b \equiv \tfrac{1}{2}\sqrt{4\beta - (\alpha - 1)^2}. \tag{14}$$

The solutions are

$$y = \begin{cases} c_1 e^{r_1 z} + c_2 e^{r_2 z} & (\alpha-1)^2 > 4\beta \\ c_1 + c_2 z)e^{az} & (\alpha-1)^2 = 4 \\ c^{az}[c_1 \cos(bz) + c_2 \sin(bz)] & (\alpha-1)^2 < 4\beta. \end{cases} \tag{15}$$

In terms of the original variable x,

$$y = \begin{cases} c_1|x|^{r_1} + c_2|x|^{r_2} & (\alpha-1)^2 > 4\beta \\ (c_1 + c_2 \ln|x|)|x|^a & (\alpha-1)^2 = 4\beta \\ |x|^a[c_1 \cos(b \ln|x|) + c_2 \sin(b \ln|x|)] & (\alpha-1)^2 < 4\beta. \end{cases} \tag{16}$$

Zwillinger (1997, p. 120) gives two other types of equations known as Euler differential equations,

$$y' = \pm\sqrt{\frac{ay^4 + by^3 + cy^2 + dy + e}{ax^3 + bx^3 + cx^2 + dx + e}} \tag{17}$$

(Valiron 1950, p. 201) and

$$y' + y^2 = \alpha x^m \quad (18)$$

(Valiron 1950, p. 212), the latter of which can be solved in terms of Bessel functions.

Euler Equation

EULER DIFFERENTIAL EQUATION, EULER'S EQUATIONS OF INVISCID MOTION, EULER FORMULA, EULER-LAGRANGE DIFFERENTIAL EQUATION

Euler Formula

The Euler formula states

$$e^{ix} = \cos x + i \sin x, \quad (1)$$

where I is the IMAGINARY NUMBER. Note that Euler's POLYHEDRAL FORMULA is sometimes also called the Euler formula, as is the EULER CURVATURE FORMULA. The equivalent expression

$$ix = \ln(\cos x + i \sin x) \quad (2)$$

had previously been published by Cotes (1714). The special case of the formula with $x = \pi$ gives the beautiful identity

$$e^{i\pi} + 1 = 0, \quad (3)$$

an equation connecting the fundamental numbers I, PI, E, 1, and 0 (ZERO).

The Euler formula can be demonstrated using a series expansion

$$e^{ix} = \sum_{n=0}^{\infty} \frac{(ix)^n}{n!}$$

$$= \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!} + i \sum_{n=1}^{\infty} \frac{(-1)^{n-1} x^{2n-1}}{(2n-1)!}$$

$$= \cos x + i \sin x. \quad (4)$$

It can also be proven using a COMPLEX integral. Let

$$z \equiv \cos\theta + i \sin\theta \quad (5)$$

$$dz = (-\sin\theta + i\cos\theta)\, d\theta = i(\cos\theta + i \sin\theta)\, d\theta$$
$$= iz\, d\theta \quad (6)$$

$$\int \frac{dz}{z} = \int i\, d\theta \quad (7)$$

$$\ln z = i\theta, \quad (8)$$

so

$$z = e^{i\theta} \equiv \cos\theta + i \sin\theta. \quad (9)$$

Euler Four-Square Identity

The amazing polynomial identity

$$(a_1^2 + a_2^2 + a_3^2 + a_4^2)(b_1^2 + b_2^2 + b_3^2 + b_4^2)$$
$$= (a_1 b_1 - a_2 b_2 - a_3 b_3 - a_4 b_4)^2$$
$$+ (a_1 b_2 + a_2 b_1 + a_3 b_4 - a_4 b_3)^2$$
$$+ (a_1 b_3 - a_2 b_4 + a_3 b_1 + a_4 b_2)^2$$
$$+ (a_1 b_4 + a_2 b_3 - a_3 b_2 + a_4 b_1)^2,$$

communicated by Euler in a letter to Goldbach on April 15, 1750 (incorrectly given as April 15, 1705–before Euler was born–in Conway and Guy 1996, p. 232). The identity also follows from the fact that the norm of the product of two QUATERNIONS is the product of the norms (Conway and Guy 1996).

Euler Integral

Euler integration was defined by Schanuel and subsequently explored by Rota, Chen, and Klain. The Euler integral of a FUNCTION $f:\mathbb{R}\to\mathbb{R}$ (assumed to be piecewise-constant with finitely many discontinuities) is the sum of

$$f(x)-\tfrac{1}{2}[f(x_+)+f(x_-)]$$

over the finitely many discontinuities of f. The n-D Euler integral can be defined for classes of functions $\mathbb{R}^n\to\mathbb{R}$. Euler integration is additive, so the Euler integral of $f+g$ equals the sum of the Euler integrals of f and g.

Euler Line

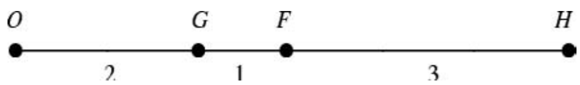
The line on which the ORTHOCENTER H, CENTROID G, CIRCUMCENTER O, DE LONGCHAMPS POINT L, NINE-POINT CENTER F, and the TANGENTIAL TRIANGLE CIRCUMCIRCLE O_T of a TRIANGLE lie. The INCENTER lies on the Euler line only if the TRIANGLE is an ISOSCELES TRIANGLE. The Euler line consists of all points with TRILINEAR COORDINATES $\alpha:\beta:\gamma$ which satisfy

$$\begin{vmatrix}\alpha & \beta & \gamma\\ \cos A & \cos B & \cos C\\ \cos B\cos C & \cos C\cos A & \cos A\cos B\end{vmatrix}=0, \quad (1)$$

which simplifies to

$$\alpha\cos A(\cos^2 B-\cos^2 C)+\beta\cos B(\cos^2 C-\cos^2 A) +\gamma\cos C(\cos^2 A-\cos^2 B)=0. \quad (2)$$

This can also be written



$$\alpha\sin(2A)\sin(B-C)+\beta\sin(2B)\sin(C-A) +\gamma\sin(2C)\sin(A-B)=0. \quad (3)$$

The Euler line may also be given parametrically in EXACT TRILINEAR COORDINATES by

$$P(\lambda)=O+\lambda H \quad (4)$$

where the following table summarized important TRIANGLES CENTERS corresponding to various values of λ (including the factor of 1/2 omitted by Oldknow 1996).

λ	TRIANGLE CENTER
-1	POINT AT INFINITY
$-\frac{1}{2}$	DE LONGCHAMPS POINT L
0	CIRCUMCENTER O
$\frac{1}{2}$	CENTROID G
1	NINE-POINT CENTER F
∞	ORTHOCENTER H

The circumcenter O, nine-point center F, centroid G, and orthocenter H form a harmonic range with

$$GO = \tfrac{1}{2} HG \tag{5}$$

$$OG = \tfrac{1}{3} HO \tag{6}$$

$$OF = \tfrac{1}{2} HO \tag{7}$$

$$FG = \tfrac{1}{6} HO \tag{8}$$

(Honsberger 1995, p. 7).

The Euler line intersects the Soddy line in the de Longchamps point, and the Gergonne line in the Evans point. The isotomic conjugate of the Euler line is called Jerabek's hyperbola (Casey 1893, Vandeghen 1965).

See also Centroid (Triangle), Circumcenter, Evans Point, Gergonne Line, Jerabek's Hyperbola, de Longchamps Point, Nine-Point Center, Orthocenter, Soddy Line, Tangential Triangle

Euler Measure

Define the Euler measure of a polyhedral set as the Euler integral of its indicator function. It is easy to show by induction that the Euler measure of a closed bounded convex polyhedron is always 1 (independent of dimension), while the Euler measure of a d-D relative-open bounded convex polyhedron is $(-1)^d$.

Euler Number

The Euler numbers, also called the secant numbers or zig numbers, are defined for $|x|<\pi/2$ by

$$\operatorname{sech} x - 1 \equiv -\frac{E_1^* x^2}{2!} + \frac{E_2^* x^4}{4!} - \frac{E_3^* x^6}{6!} + \ldots \tag{1}$$

$$\sec x - 1 \equiv \frac{E_1^* x^2}{2!} + \frac{E_2^* x^4}{4!} - \frac{E_3^* x^6}{6!} + \ldots, \tag{2}$$

where sech is the hyperbolic secant and sec is the secant. Euler numbers give the number of odd alternating permutations and are related to Genocchi numbers. The base e of the natural logarithm is sometimes known as Euler's number.

Some values of the Euler numbers are

$$E_1^* = 1$$

$$E_2^* = 5$$

$$E_3^* = 61$$

$$E_4^* = 1,385$$

$$E_5^* = 50,521$$

$$E_6^* = 2,702,765$$

$$E_7^* = 199,360,981$$

$$E_8^* = 19,391,512,145$$

$$E_9^* = 2,404,879,675,441$$

$$E_{10}^* = 370,371,188,237,525$$

$$E_{11}^* = 69,348,874,393,137,901$$

$$E_{12}^* = 15,514,534,163,557,086,905$$

(Sloane's A000364). The first few prime Euler numbers E_n* occur for $n = 2$, 3, 19, 227, 255, ... (Sloane's A014547) up to a search limit of $n = 1415$.

The slightly different convention defined by

$$E_{2n} = (-1)^n E_n^* \tag{3}$$

$$E_{2n+1} = 0 \tag{4}$$

is frequently used. These are, for example, the Euler numbers computed by the *Mathematica* function `EulerE[n]`. This definition has the particularly simple series definition

$$\operatorname{sech} x \equiv \sum_{k=0}^{\infty} \frac{E_k x^k}{k!} \tag{5}$$

and is equivalent to

$$E_n = 2^n E_n(\tfrac{1}{2}), \tag{6}$$

where $E_n(x)$ is an EULER POLYNOMIAL. The Euler numbers have the ASYMPTOTIC SERIES

$$E_{2n} \sim (-1)^n 8\sqrt{\frac{n}{\pi}}\left(\frac{4n}{\pi e}\right)^{2n}. \tag{7}$$

To confuse matters further, the EULER CHARACTERISTIC is sometimes also called the "Euler number."

Euler Number (Finite Complex)

The Euler number of a finite complex K is defined by

$$\chi(K) = \sum (-1)^p \operatorname{rank}(C_p(K)).$$

The Euler number is a topological invariant.

See also EULER CHARACTERISTIC, LEFSCHETZ NUMBER

References

Munkres, J. R. *Elements of Algebraic Topology.* Perseus Press, p. 124, 1993.

Euler Parameters

The four parameters e_0, e_1, e_2, and e_3 describing a finite rotation about an arbitrary axis. The Euler parameters are defined by

$$e_0 \equiv \cos\left(\frac{\phi}{2}\right) \tag{1}$$

$$\mathbf{e} \equiv \begin{bmatrix} e_1 \\ e_2 \\ e_3 \end{bmatrix} = \hat{\mathbf{n}} \sin\left(\frac{\phi}{2}\right), \tag{2}$$

and are a QUATERNION in scalar-vector representation

$$(e_0, \mathbf{e}) = e_0 + e_1 i + e_2 j + e_3 k. \tag{3}$$

Because EULER'S ROTATION THEOREM states that an arbitrary rotation may be described by only three parameters, a relationship must exist between these four quantities

$$e_0^2 + \mathbf{e} \cdot \mathbf{e} = e_0^2 + e_1^2 + e_2^2 + e_3^2 = 1 \tag{4}$$

(Goldstein 1980, p. 153). The rotation angle is then related to the Euler parameters by

$$\cos\phi = 2e_0^2 - 1 = e_0^2 - \mathbf{e} \cdot \mathbf{e} = e_0^2 - e_1^2 - e_2^2 - e_3^2 \tag{5}$$

$$\hat{\mathbf{n}} \sin\phi = 2\mathbf{e} e_0. \tag{6}$$

The Euler parameters may be given in terms of the EULER ANGLES by

$$e_0 = \cos[\tfrac{1}{2}(\phi+\psi)] \cos(\tfrac{1}{2}\theta) \tag{7}$$

$$e_1 = \sin[\tfrac{1}{2}(\phi-\psi)] \sin(\tfrac{1}{2}\theta) \tag{8}$$

$$e_2 = \cos[\tfrac{1}{2}(\phi-\psi)] \sin(\tfrac{1}{2}\theta) \tag{9}$$

$$e_3 = \sin[\tfrac{1}{2}(\phi+\psi)] \cos(\tfrac{1}{2}\theta) \tag{10}$$

(Goldstein 1980, p. 155).

Using the Euler parameters, the ROTATION FORMULA becomes

$$\mathbf{r}' = \mathbf{r}(e_0^2 - e_1^2 - e_2^2 - e_3^2) + 2\mathbf{e}(\mathbf{e} \cdot \mathbf{r}) + (\mathbf{r} \times \hat{\mathbf{n}}) \sin\phi, \tag{11}$$

and the ROTATION MATRIX becomes

$$\begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} = \mathsf{A} \begin{bmatrix} x \\ y \\ z \end{bmatrix}, \tag{12}$$

where the elements of the matrix are

$$a_{ij} = \delta_{ij}(e_0^2 - e_k e_k) + 2e_i e_j + 2\epsilon_{ijk} e_0 e_k. \tag{13}$$

Here, EINSTEIN SUMMATION has been used, δ_{ij} is the KRONECKER DELTA, and ϵ_{ijk} is the PERMUTATION SYMBOL. Written out explicitly, the matrix elements are

$$a_{11} = e_0^2 + e_1^2 - e_2^2 - e_3^2 \tag{14}$$

$$a_{12} = 2(e_1 e_2 + e_0 e_3) \tag{15}$$

$$a_{13} = 2(e_1 e_3 - e_0 e_2) \tag{16}$$

$$a_{21} = 2(e_1 e_2 - e_0 e_3) \tag{17}$$

$$a_{22} = e_0^2 - e_1^2 + e_2^2 - e_3^2 \quad (18)$$

$$a_{23} = 2(e_2e_3 + e_0e_1) \quad (19)$$

$$a_{31} = 2(e_1e_3 + e_0e_2) \quad (20)$$

$$a_{32} = 2(e_2e_3 - e_0e_1) \quad (21)$$

$$a_{33} = e_0^2 - e_1^2 - e_2^2 + e_3^2. \quad (22)$$

Euler Polyhedral Formula

POLYHEDRAL FORMULA

Euler Polynomial

The Euler polynomial $E_n(x)$ is given by the APPELL SEQUENCE with

$$g(t) = \tfrac{1}{2}(e^t + 1), \quad (1)$$

giving the GENERATING FUNCTION

$$\frac{2e^{xt}}{e^t + 1} \equiv \sum_{n=0}^{\infty} E_n(x)\frac{t^n}{n!}. \quad (2)$$

Roman (1984, p. 100) defines a generalization $E_n^{(\alpha)}(x)$ for which $E_n(x) = E_n^{(1)}(x)$. Euler polynomials are related to the BERNOULLI NUMBERS by

$$E_{n-1}(x) = \frac{2^n}{n}\left[B_n\left(\frac{x+1}{2}\right) - B_n\left(\frac{x}{2}\right)\right] \quad (3)$$

$$= \frac{2}{n}\left[B_n(x) - 2^n B_n\left(\frac{x}{2}\right)\right] \quad (4)$$

$$E_{n-2}(x) = 2\binom{n}{2}^{-1}\sum_{k=0}^{n-2}\binom{n}{2}[(2^{n-k}-1)B_{n-k}B_k(x)], \quad (5)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. Setting $x = 1/2$ and normalizing by 2^n gives the EULER NUMBER

$$E_n = 2^n E_n(\tfrac{1}{2}). \quad (6)$$

Call $E_n' = E_n(0)$, then the first few terms are $-1/2$, 0, 1/4, $-1/2$, 0, 17/8, 0, 31/2, 0, ... The terms are the same but with the SIGNS reversed if $x = 1$. These values can be computed using the double sum

$$E_n(0) = 2^{-n}\sum_{j=1}^{n}\left[(-1)^{j+n+1}j^k\sum_{k=0}^{n-j}\binom{n+1}{k}\right]. \quad (7)$$

The BERNOULLI NUMBERS B_n for $n > 1$ can be expressed in terms of the E_n' by

$$B_n = -\frac{nE_{n-1}'}{2(2^n-1)}. \quad (8)$$

The Newton expansion of the Euler polynomials is given by

$$E_n(x) = \sum_{j=0}^{n}\sum_{k=j}^{n}\binom{-1}{j}\frac{1}{2j}(k)_j S(n,\ k)(x)_{k-j}, \quad (9)$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, $(k)_j$ is a FALLING FACTORIAL, and $S(n,\ k)$ is a STIRLING NUMBER OF THE SECOND KIND (Roman 1984, p. 101).
The Euler polynomials satisfy the identity

$$\sum_{k=0}^{n}\binom{n}{2}E_k(z)E_{n-k}(w) = 2(1-w-z)E_n(z+w) + 2E_{n+1}(z+w) \quad (10)$$

for n a NONNEGATIVE INTEGER.

Euler Polynomial Identity

EULER FOUR-SQUARE IDENTITY

Euler Power Conjecture

EULER'S SUM OF POWERS CONJECTURE

Euler Product

For $s > 1$, the RIEMANN ZETA FUNCTION is given by

$$\zeta(s) \equiv \sum_{n=1}^{\infty} \frac{1}{n^s} = \prod_{n=1}^{\infty} \frac{1}{1 - \frac{1}{p_n^s}},$$

where p_i is the ith PRIME. This is Euler's product (Whittaker and Watson 1990).

Let $s \to 1$, then the terms in the product for upper limits $n = 1, 2, ...,$ are given by 2, 4, 6, 15/2, 35/4, 77/8, 1001/96, 17017/1536, ... (Sloane's A050298 and A050299). The limiting case as $n \to \infty$ gives MERTENS THEOREM,

$$e^{\gamma} = \lim_{n\to\infty} \frac{1}{\ln n} \prod_{i=1}^{n} \frac{1}{1 - \frac{1}{pi}},$$

where γ is the EULER-MASCHERONI CONSTANT.

Euler Quartic Conjecture

Euler conjectured that there are no POSITIVE INTEGER solutions to the quartic DIOPHANTINE EQUATION

$$A^4 = B^4 + C^4 + D^4.$$

This conjecture was disproved by Elkies (1988), who found an infinite class of solutions.

Euler Square

A square ARRAY made by combining n objects of two types such that the first and second elements form LATIN SQUARES. Euler squares are also known as GRAECO-LATIN SQUARES, GRAECO-ROMAN SQUARES, or LATIN-GRAECO SQUARES. For many years, Euler squares were known to exist for $n = 3$, 4, and for every ODD n except $n = 3k$. EULER'S GRAECO-ROMAN SQUARES CONJECTURE maintained that there do not exist Euler squares of order $n = 4k + 2$ for $k = 1, 2, ...$. However, such squares were found to exist in 1959, refuting the CONJECTURE.

Euler Sum

In response to a letter from Goldbach, Euler considered DOUBLE SUMS OF THE FORM

$$s_h(m, n) = \sum_{k=1}^{\infty}\left(1+\frac{1}{2}+\ldots+\frac{1}{k}\right)^m (k+1)^{-n} \quad (1)$$

$$= \sum_{k=1}^{\infty}[\gamma+\psi_0(k+1)]^m (k+1)^{-n} \quad (2)$$

with $m \geq 1$ and $n \geq 2$ and where γ is the EULER-MASCHERONI CONSTANT and $\Psi(x) = \psi_0(x)$ is the DIGAMMA FUNCTION. Euler found explicit formulas in terms of the RIEMANN ZETA FUNCTION for $s(1, n)$ with $n \geq 2$, and E. Au-Yeung numerically discovered

$$\sum_{k=1}^{\infty}\left(1+\frac{1}{2}+\ldots+\frac{1}{k}\right)^2 k^{-2} = \tfrac{17}{4}\zeta(4), \quad (3)$$

where $\zeta(z)$ is the RIEMANN ZETA FUNCTION, which was subsequently rigorously proven true (Borwein and Borwein 1995). Sums involving k^{-n} can be re-expressed in terms of sums the form $(k+1)^{-n}$ via

$$\sum_{k=1}^{\infty}\left(1+\frac{1}{2^m}+\ldots+\frac{1}{k^m}\right)k^{-n}$$

$$= \sum_{k=0}^{\infty}\left[1+\frac{2}{2^m}+\ldots+\frac{1}{(k+1)^m}\right](k+1)^{-n}$$

$$= \sum_{k=1}^{\infty}\left(1+\frac{1}{2^m}+\ldots+\frac{1}{k^m}\right)(k+1)^{-n} + \sum_{k=1}^{\infty} k^{-(m+n)}$$

$$\equiv \sigma_h(m, n) + \zeta(m+n) \quad (4)$$

$$\sum_{k=1}^{\infty}\left(1+\frac{1}{2}+\ldots+\frac{1}{k}\right)^2 k^{-n}$$
$$= s_h(2, n) + 2s_h(1, n+1) + \zeta(n+2), \quad (5)$$

where σ_h is defined below.

Bailey *et al.* (1994) subsequently considered sums OF THE FORMS

$$s_h(m, n) = \sum_{k=1}^{\infty}\left(1+\frac{1}{2}+\ldots+\frac{1}{k}\right)^m (k+1)^{-n} \quad (6)$$

$$s_a(m, n) = \sum_{k=1}^{\infty}\left[1-\frac{1}{2}+\ldots+\frac{(-1)^{k+1}}{k}\right]^m (k+1)^{-n} \quad (7)$$

$$a_h(m, n) = \sum_{k=1}^{\infty}\left(1+\frac{1}{2}+\ldots+\frac{1}{k}\right)^m (-1)^{k+1}(k+1)^{-n} \quad (8)$$

$$a_a(m, n) = \sum_{k=1}^{\infty}\left(1-\frac{1}{2}+\ldots+\frac{(-1)^{k+1}}{k}\right)^m (-1)^{k+1}$$
$$\times (k+1)^{-n} \quad (9)$$

$$\sigma_h(m, n) = \sum_{k=1}^{\infty}\left(1+\frac{1}{2^m}+\ldots+\frac{1}{k^m}\right)(k+1)^{-n} \quad (10)$$

$$\sigma_a(m, n) = \sum_{k=1}^{\infty}\left(1-\frac{1}{2^m}+\ldots+\frac{(-1)^{k+1}}{k^m}\right)(k+1)^{-n} \quad (11)$$

$$\alpha_h(m, n) = \sum_{k=1}^{\infty}\left(1+\frac{1}{2^m}+\ldots+\frac{1}{k^m}\right)(-1)^{k+1}$$
$$\times (k+1)^{-n} \quad (12)$$

$$\alpha_a(m, n) = \sum_{k=1}^{\infty}\left(1-\frac{1}{2^m}+\ldots+\frac{(-1)^{k+1}}{k^m}\right)(-1)^{k+1}$$
$$\times (k+1)^{-n}, \quad (13)$$

where s_h and s_a have the special forms

$$s_h = \sum_{k=1}^{\infty}[\gamma+\psi_0(n+1)]^m (k+1)^{-n} \quad (14)$$

$$a_a = \sum_{k=1}^{\infty}\{\ln 2 + \tfrac{1}{2}(-1)^n[\psi_0(\tfrac{1}{2}n+\tfrac{1}{2}) - \psi_0(\tfrac{1}{2}n+1)]\}^m$$
$$\times (k+1)^{-m}. \quad (15)$$

Analytic single or double sums over $\zeta(z)$ can be constructed for

$$s_h(2, n) = \tfrac{1}{3}n(n+1)\zeta(n+2) + \zeta(2)\zeta(n)$$
$$-\tfrac{1}{2}n\sum_{k=0}^{n-2}\zeta(n-k)\zeta(k+2) \quad (16)$$

$$s_h(2, 2n-1) = \tfrac{1}{6}(2n^2-7n-3)\zeta(2n+1) + \zeta(2)\zeta(2n-1)$$
$$-\tfrac{1}{2}\sum_{k=1}^{n-2}(2k-1)\zeta(2n-1-2k)\zeta(2k+2) \quad (17)$$

$$\sigma_h(2, 2n-1)$$
$$= -\tfrac{1}{2}(2n^2+n+1)\zeta(2n+1) + \zeta(2)\zeta(2n-1) \quad (18)$$

$\sigma_h(m \text{ even}, n \text{ odd})$

$$= \tfrac{1}{2}\left[\binom{m+n}{m} - 1\right]\zeta(m+n) + \zeta(m)\zeta(n) - \sum_{j=1}^{m+n}\left[\binom{2j-2}{m-1} + \binom{2j-2}{n-1}\right] \quad (19)$$

$\sigma_h(m \text{ odd}, n \text{ even})$

$$= -\tfrac{1}{2}\left[\binom{m+n}{m} + 1\right]\zeta(m+n) + \sum_{k=1}^{m+n}\left[\binom{2j-2}{m-1} + \binom{2j-2}{n-1}\right] \quad (20)$$

where $\binom{n}{m}$ is a BINOMIAL COEFFICIENT. Explicit formulas inferred using the PSLQ ALGORITHM include

$$s_h(2, 2) = \tfrac{3}{2}\zeta(4) + \tfrac{1}{2}[\zeta(2)]^2 \quad (21)$$

$$= \tfrac{11}{360}\pi^4 \quad (22)$$

$$s_h(2, 4) = \tfrac{2}{3}\zeta(6) - \tfrac{1}{3}\zeta(2)\zeta(4) + \tfrac{1}{3}[\zeta(2)]^3 - [\zeta(3)]^2 \quad (23)$$

$$= \tfrac{37}{22680}\pi^6 - [\zeta(3)]^2 \quad (24)$$

$$s_h(3, 2) = \tfrac{15}{2}\zeta(5) + \zeta(2)\zeta(3) \quad (25)$$

$$s_h(3, 3) = -\tfrac{33}{16}\zeta(6) + 2[\zeta(3)]^2 \quad (26)$$

$$s_h(3, 4) = \tfrac{119}{16}\zeta(7) - \tfrac{33}{4}\zeta(3)\zeta(4) + 2\zeta(2)\zeta(5) \quad (27)$$

$$s_h(3, 6) = \tfrac{197}{24}\zeta(9) - \tfrac{33}{4}\zeta(4)\zeta(5) - \tfrac{37}{8}\zeta(3)\zeta(6) + [\zeta(3)]^3 + 3\zeta(2)\zeta(7) \quad (28)$$

$$s_h(4, 2) = \tfrac{859}{24}\zeta(6) + 3[\zeta(3)]^2 \quad (29)$$

$$s_h(4, 3) = -\tfrac{109}{8}\zeta(7) + \tfrac{37}{2}\zeta(3)\zeta(4) - 5\zeta(2)\zeta(5) \quad (30)$$

$$s_h(4, 5) = -\tfrac{29}{2}\zeta(9) + \tfrac{37}{2}\zeta(4)\zeta(5) + \tfrac{33}{4}\zeta(3)\zeta(6) - \tfrac{8}{3}[\zeta(3)]^3 - 7\zeta(2)\zeta(7) \quad (31)$$

$$s_h(5, 2) = \tfrac{1855}{16}\zeta(7) + 33\zeta(3)\zeta(4) + \tfrac{57}{2}\zeta(2)\zeta(5) \quad (32)$$

$$s_h(5, 4) = \tfrac{890}{9}\zeta(9) + 66\zeta(4)\zeta(5) - \tfrac{4295}{24}\zeta(3)\zeta(6) - 5[\zeta(3)]^3 + \tfrac{265}{8}\zeta(2)\zeta(7) \quad (33)$$

$$s_h(6, 3) = -\tfrac{3073}{12}\zeta(9) - 243\zeta(4)\zeta(5) + \tfrac{2097}{4}\zeta(3)\zeta(6) + \tfrac{67}{3}[\zeta(3)]^3 - \tfrac{651}{8}\zeta(2)\zeta(7) \quad (34)$$

$$s_h(7, 2) = \tfrac{134701}{36}\zeta(9) + \tfrac{15697}{8}\zeta(4)\zeta(5) + \tfrac{29555}{24}\zeta(3)\zeta(6) + 56[\zeta(3)]^3 + \tfrac{3287}{4}\zeta(2)\zeta(7), \quad (35)$$

$$a_h(2, 2) = -2\mathrm{Li}_4(\tfrac{1}{2}) - \tfrac{1}{12}(\ln 2)^4 + \tfrac{99}{48}\zeta(4) - \tfrac{7}{4}\zeta(3)\ln 2 + \tfrac{1}{2}\zeta(2)(\ln 2)^2 \quad (36)$$

$$a_h(2, 3) = -4\mathrm{Li}_5(\tfrac{1}{2}) - 4(\ln 2)\mathrm{Li}_4(\tfrac{1}{2}) - \tfrac{2}{15}(\ln 2)^5 + \tfrac{107}{32}\zeta(5) - \tfrac{7}{4}\zeta(3)(\ln 2)^2 + \tfrac{2}{3}\zeta(2)(\ln 2)^3 + \tfrac{3}{8}\zeta(2)\zeta(3) \quad (37)$$

$$a_h(3, 2) = 6\mathrm{Li}_5(\tfrac{1}{2}) + 6(\ln 2)\mathrm{Li}_4(\tfrac{1}{2}) + \tfrac{1}{5}(\ln 2)^5 - \tfrac{33}{8}\zeta(5) + \tfrac{21}{8}\zeta(3)(\ln 2)^2 - \zeta(2)(\ln 2)^3 - \tfrac{15}{16}\zeta(2)\zeta(3), \quad (38)$$

and

$$a_a(2, 2) = -4\mathrm{Li}_4(\tfrac{1}{2}) - \tfrac{1}{6}(\ln 2)^4 + \tfrac{37}{16}\zeta(4) + \tfrac{7}{4}\zeta(3)(\ln 2) - 2\zeta(\ln 2)^2 \quad (39)$$

$$a_a(2, 3) = 4(\ln 2)\mathrm{Li}_4(\tfrac{1}{2}) + \tfrac{1}{6}(\ln 2)^5 - \tfrac{79}{32}\zeta(5) + \tfrac{11}{8}\zeta(4)(\ln 2) - \zeta(2)(\ln 2)^3 \quad (40)$$

$$a_a(3, 2) = 30\mathrm{Li}_5(\tfrac{1}{2}) - \tfrac{1}{4}(\ln 2)^5 - \tfrac{1813}{64}\zeta(5) + \tfrac{285}{16}\zeta(4)(\ln 2) + \tfrac{21}{8}\zeta(3)(\ln 2)^2 - \tfrac{7}{2}\zeta(2)(\ln 2)^3 + \tfrac{3}{4}\zeta(2)\zeta(3), \quad (41)$$

where Li_n is a POLYLOGARITHM, and $\zeta(z)$ is the RIEMANN ZETA FUNCTION (Bailey and Plouffe). Of these, only $s_h(3, 2)$, $s_h(3, 3)$ and the identities for $s_a(m, n)$, $a_h(m, n)$ and $a_a(m, n)$ have been rigorously established.

Euler System

A mathematical structure first introduced by Kolyvagin (1990) and defined as follows. Let T be a finite-dimensional p-adic representation of the GALOIS GROUP of a NUMBER FIELD K. Then an Euler system for T is a collection of COHOMOLOGY CLASSES $\mathbf{c}_F \in H^1(F, T)$ for a family of Abelian extensions F of K, with a relation between $\mathbf{c}_{F'}$ and $\mathbf{c}_F$ whenever $F \subset F'$ (Rubin 2000, p. 4).

Wiles' proof of FERMAT'S LAST THEOREM via the TANIYAMA-SHIMURA CONJECTURE made use of Euler systems.

Euler Totient Function

TOTIENT FUNCTION

Euler Transform

There are (at least) three types of Euler transforms (or transformations). The first is a set of transformations of HYPERGEOMETRIC FUNCTIONS, called EULER'S HYPERGEOMETRIC TRANSFORMATIONS.

The second type of Euler transform is a technique for SERIES CONVERGENCE IMPROVEMENT which takes a convergent alternating series

$$\sum_{k=0}^{\infty}(-1)^k a_k = a_0 - a_1 + a_2 - \ldots \quad (1)$$

into a series with more rapid convergence to the same value to

$$s = \sum_{k=0}^{\infty} \frac{(-1)^k \Delta^k a_0}{2^{k+1}}, \quad (2)$$

where the FORWARD DIFFERENCE is defined by

$$\Delta^k a_0 = \sum_{m=0}^{k} \equiv (-1)^m \binom{k}{m} a_{k-m} \quad (3)$$

(Abramowitz and Stegun 1972; Beeler *et al.* 1972).

The third type of Euler transform is a relationship between certain types of INTEGER SEQUENCES (Sloane and Plouffe 1995, pp. 20–1). If a_1, a_2, ... and b_1, b_2, ... are related by

$$1 + \sum_{n=1}^{\infty} b_n x^n = \prod_{i=1}^{\infty} \frac{1}{(1 - x^i)^{a_1}} \quad (4)$$

or, in terms of GENERATING FUNCTIONS $A(x)$ and $B(x)$,

$$1 + B(x) = \exp\left[\sum_{k=1}^{\infty} \frac{A(x^k)}{k}\right], \quad (5)$$

then $\{b_n\}$ is said to be the Euler transform of $\{a_n\}$ (Sloane and Plouffe 1995, p. 20). The Euler transform can be effected by introducing the intermediate series c_1, c_2, ... given by

$$c_n = \sum_{d|n} d a_d, \quad (6)$$

then

$$b_n = \frac{1}{n}\left[c_n + \sum_{k=1}^{n-1} c_k b_{n-k}\right], \quad (7)$$

with $b_1 = c_1$. Similarly, the inverse transform can be effected by computing the intermediate series as

$$c_n = n b_n - \sum_{k=1}^{n-1} c_k b_{n-1}, \quad (8)$$

then

$$a_n = \frac{1}{n} \sum_{d|n} \mu\left(\frac{n}{d}\right) c_d, \quad (9)$$

where $\mu(n)$ is the MÖBIUS FUNCTION.

In GRAPH THEORY, if a_n is the number of UNLABELED CONNECTED GRAPHS on n nodes satisfying some property, then b_n is the *total* number of UNLABELED GRAPHS (connected or not) with the same property. This application of the Euler transform is called RIDDELL'S FORMULA for unlabeled graph (Sloane and Plouffe 1995, p. 20).

There are also important number theoretic applications of the Euler transform. For example, if there are a_1 kinds of parts of size 1, a_2 kinds of parts of size 2, etc., in a given type of partition, then the Euler transform b_n of a_n is the number of partitions of n into these integer parts. For example, if $a_n = 1$ for all n, then b_n is the number of partitions of n into integer parts. Similarly, if $a_n = 1$ for n PRIME and $a_n = 0$ for n composite, then b_n is the number of partitions of n into prime parts (Sloane and Plouffe 1995, p. 21). Other applications are given by Andrews (1986), Andrews and Baxter (1989), and Cameron (1989).

Euler Walk

EULERIAN TRAIL

Euler Zigzag Number

The number of ALTERNATING PERMUTATIONS for n elements is sometimes called an Euler zigzag number. Denote the number of ALTERNATING PERMUTATIONS on n elements for which the first element is k by $E(n,\ k)$. Then $E(1,\ 1) = 1$ and

$$E(n,\ k) = \begin{cases} 0 & \text{for } k \geq n \text{ or } k < 1 \\ E(n,\ k+1) + E(n-1,\ n-k) & \text{otherwise.} \end{cases}$$

where $E(n,\ k)$ is an ENTRINGER NUMBER.

Euler's 6n+1 Theorem

Every PRIME OF THE FORM $6n+1$ can be written in the form $x^2 + 3y^2$.

Euler's Addition Theorem

Let $g(x) \equiv (1-x^2)(1-k^2x^2)$. Then

$$\int_0^a \frac{dx}{\sqrt{g(x)}} + \int_0^b \frac{dx}{\sqrt{g(x)}} = \int_0^c \frac{dx}{\sqrt{g(x)}},$$

where

$$c \equiv \frac{b\sqrt{g(a)} + a\sqrt{g(b)}}{\sqrt{1 - k^2a^2b^2}}.$$

Euler's Circle

NINE-POINT CIRCLE

Euler's Conjecture

Define $g(k)$ as the quantity appearing in WARING'S PROBLEM, then Euler conjectured that

$$g(k) = 2^k + \left\lfloor \left(\frac{3}{2}\right)^k \right\rfloor - 2,$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION.

See also WARING'S PROBLEM

Euler's Criterion

For p an ODD PRIME and a POSITIVE INTEGER a which is not a multiple of p,

$$a^{(p-1)/2} \equiv \left(\frac{a}{p}\right) \pmod{p},$$

where $(a|p)$ is the LEGENDRE SYMBOL.

Euler's Factorization Method

A factorization algorithm which works by expressing N as a QUADRATIC FORM in two different ways. Then

$$N=a^2+b^2=c^2+d^2, \tag{1}$$

so

$$a^2-c^2=d^2-b^2 \tag{2}$$

$$(a-c)(a+c)=(d-b)(d+b). \tag{3}$$

Let k be the GREATEST COMMON DIVISOR of $a-c$ and $d-b$ so

$$a-c=kl \tag{4}$$

$$d-b=km \tag{5}$$

$$(l,\ m)=1, \tag{6}$$

(where $(l,\ m)$ denotes the GREATEST COMMON DIVISOR of l and m), and

$$l(a+c)=m(d+b). \tag{7}$$

But since $(l,\ m)=1$, $m|a+c$ and

$$a+c=mn, \tag{8}$$

which gives

$$b+d=ln, \tag{9}$$

so we have

$$[(\tfrac{1}{2}k)^2+(\tfrac{1}{2}n)^2](l^2+m^2)=\tfrac{1}{4}(k^2+n^2)(l^2+m^2)$$

$$=\tfrac{1}{4}[(kn)^2+(kl)^2+(nm)^2+(nl)^2]$$

$$=\tfrac{1}{4}[(d-b)^2+(a-c)^2+(a+c)^2+(d+b)^2]$$

$$=\tfrac{1}{4}(2a^2+2b^2+2c^2+2d^2)$$

$$=\tfrac{1}{4}(2N+2N)=N. \tag{10}$$

Euler conjectured that there do not exist GRAECO-ROMAN SQUARES (now known as EULER SQUARES) of order $n=4k+2$ for $k=1,\ 2,\ \ldots$. In fact, MacNeish (1921–922) published a purported proof of this conjecture (Bruck and Ryser 1949). While it is true that no such square of order six exists, such squares were found to exist for *all* other orders of the form $4k+2$ by Bose, Shrikhande, and Parker in 1959 (Wells 198, p. 77), refuting the CONJECTURE (and establishing unequivocally the invalidity of MacNeish's "proof").

Euler's Homogeneous Function Theorem

Let $f(x,\ y)$ be a HOMOGENEOUS FUNCTION of order n so that

$$f(tx,\ ty) = t^n f(x,\ y). \qquad (1)$$

Then define $x' \equiv xt$ and $y' \equiv yt$. Then

$$nt^{n-1} f(x,\ y) = \frac{\partial f}{\partial x'} \frac{\partial x'}{\partial t} + \frac{\partial f}{\partial y'} \frac{\partial y'}{\partial t}$$

$$= x \frac{\partial f}{\partial x'} + y \frac{\partial f}{\partial y'} = x \frac{\partial f}{\partial (xt)} + y \frac{\partial f}{\partial (yt)}. \qquad (2)$$

Let $t = 1$, then

$$x \frac{\partial f}{\partial x} + y \frac{\partial f}{\partial y} = nf(x,\ y). \qquad (3)$$

This can be generalized to an arbitrary number of variables

$$x_i \frac{\partial f}{\partial x_i} = nf(\mathbf{x}), \qquad (4)$$

where EINSTEIN SUMMATION has been used.

Euler's Hypergeometric Transformations

$$ {}_2F_1(a,\ b;\ c;\ z) = \int_0^1 \frac{t^{b-1}(1-t)^{c-b-1}}{(1-tz)^a}\,dt, \qquad (1)$$

where ${}_2F_1(a,\ b;\ c;\ z)$ is a HYPERGEOMETRIC FUNCTION. The solution can be written using the Euler's transformations

$$t \to t \qquad (2)$$

$$t \to 1-t \qquad (3)$$

$$t \to (1-z-tz)^{-1} \qquad (4)$$

$$t \to \frac{1-t}{1-tz} \qquad (5)$$

in the equivalent forms

$$ {}_2F_1(a,\ b;\ c;\ z)$$

$$= (1-z)^{-a}\,{}_2F_1(a,\ c-b;\ c;\ z/(z-1)) \qquad (6)$$

$$= (1-z)^{-b}\,{}_2F_1(c-a,\ b;\ c;\ z/(z-1)) \qquad (7)$$

$$= (1-z)^{c-a-b}\,{}_2F_1(c-a,\ c-b;\ c;\ z). \qquad (8)$$

Euler's Rule

The numbers $2^n pq$ and $2^n r$ are an AMICABLE PAIR if the three INTEGERS

$$p \equiv 2^m(2^{n-m}+1)-1 \qquad (1)$$

$$q \equiv 2^n(2^{n-m}+1)-1 \qquad (2)$$

$$r \equiv 2^{n+m}(2^{n-m}+1)^2-1 \qquad (3)$$

are all PRIME NUMBERS for some POSITIVE INTEGER m satisfying $1 \le m \le n-1$ (Dickson 1952, p. 42). However, there are many AMICABLE PAIRS which do not

satisfy Euler's rule, so it is a SUFFICIENT but not NECESSARY condition for amicability. Euler's rule is a generalization of THÂBIT IBN KURRAH RULE.

For example, Euler's rule is satisfied for $(n, m) =$ (2, 1), (4, 4), (6, 7), (8, 1), (40, 29), ..., corresponding to the triples $(p, q, r) =$ (5, 11, 71), (23, 47, 1151), (191, 383, 73727), ..., giving the AMICABLE PAIRS (220, 284), (17296, 18416), (9363584, 9437056), ...

Euler's Series Transformation

Accelerates the rate of CONVERGENCE for an ALTERNATING SERIES

$$S = \sum_{s=0}^{\infty} (-1)^s u_s$$
$$= u_0 - u_1 + u_2 - \ldots - u_{n-1} + \sum_{s=0}^{\infty} \frac{(-1)^2}{2^{s+1}} [\Delta^s u_n] \quad (1)$$

for n EVEN and Δ the FORWARD DIFFERENCE operator

$$\Delta^k u_n \equiv \sum_{m=0}^{k} (-1)^m \binom{k}{m} u_{n+k-m}, \quad (2)$$

where $\binom{k}{m}$ are BINOMIAL COEFFICIENTS. The POSITIVE terms in the series can be converted to an ALTERNATING SERIES using

$$\sum_{r=1}^{\infty} v_r = \sum_{r=1}^{\infty} (-1)^{r-1} w_r, \quad (3)$$

where

$$w_r \equiv v_r + 2v_{2r} + 4v_{4r} + 8v_{8r} + \ldots. \quad (4)$$

Euler's Spiral

CORNU SPIRAL

Euler's Sum of Powers Conjecture

Euler conjectured that at least n nth POWERS are required for $n > 2$ to provide a sum that is itself an nth POWER. The conjecture was disproved by Lander and Parkin (1967) with the counterexample

$$27^5 + 84^5 + 110^5 + 133^5 = 144^5.$$

Ekl (1998) defined Euler's extended conjecture as the assertion that there are no solutions to the $k.m.n$ DIOPHANTINE EQUATION

$$a_1^k + a_2^k + \ldots + a_m^k = b_1^k + b_2^k + \ldots + b_n^k,$$

with a_i and b_i not necessarily distinct, such that $m + n < k$. There are no known counterexamples to this conjecture (Ekl 1998). Ekl (1998) defines the Euler conjecture number as the minimum known value of $\Delta \equiv m + n - k$. The following table gives the smallest known values.

k	Soln.	Δ	Reference
4	4.1.3	0	Elkies 1988
5	5.1.4	0	Lander *et al.* 1967

Euler's Theorem

A generalization of FERMAT'S LITTLE THEOREM. Euler published a proof of the following more general theorem in 1736. Let $\phi(n)$ denote the TOTIENT FUNCTION. Then

$$a^{\phi(n)} \equiv 1 \pmod{n}$$

for all a RELATIVELY PRIME to n.

See also CHINESE HYPOTHESIS, EULER'S DISPLACEMENT THEOREM, EULER'S DISTRIBUTION THEOREM, FERMAT'S LITTLE THEOREM, TOTIENT FUNCTION

Euler's Totient Rule

The number of bases in which $1/p$ is a REPEATING DECIMAL (actually, repeating b-ary) of length l is the same as the number of FRACTIONS $0/(p-1)$, $1/(p-1)$, ..., $(p-2)/(p-1)$ which have reduced DENOMINATOR l. For example, in bases 2, 3, ..., 6, 1/7 is given by

$$\begin{aligned}\tfrac{1}{7} &= 0.001001001001\ldots_2\\ &= 0.010212010212\ldots_3\\ &= 0.021021021020\ldots_4\\ &= 0.032412032412\ldots_5\\ &= 0.050505050505\ldots_6,\end{aligned}$$

which have periods 3, 6, 3, 6, and 2, respectively, corresponding to the DENOMINATORS 6, 3, 2, 3, and 6 of

$$\frac{1}{6}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \text{ and } \frac{5}{6}.$$

Euler's Triangle

The triangle of numbers $A_{n,k}$ given by

$$A_{n,1} = A_{n,n} = 1$$

and the RECURRENCE RELATION

$$A_{n+1,k} = kA_{n,k} + (n+2-k)A_{n,k-1}$$

for $k \in [2, n]$, where $A_{n,k}$ are EULERIAN NUMBERS.

1

1 1

1 4 1

1 11 11 1

1 26 66 26 1

1 57 302 302 57 1

The numbers 1, 1, 1, 1, 4, 1, 1, 11, 11, 1, ... are Sloane's A008292. Amazingly, the Z-TRANSFORMS of t^n

$$\frac{(z-1)^n}{T^n z} Z[t^n] = \frac{(1-z)^n}{T^n z} \lim_{x\to 0} \frac{\partial^n}{\partial x^n}\left(\frac{z}{z-e^{-xT}}\right)$$

are generators for Euler's triangle.

A SPHERICAL TRIANGLE is sometimes also called Euler's triangle.

EulerE

EULER NUMBER, EULER POLYNOMIAL

EulerGamma

EULER-MASCHERONI CONSTANT

Eulerian Circuit

An EULERIAN TRAIL which starts and ends at the same VERTEX. In other words, it is a GRAPH CYCLE which uses each EDGE exactly once. The term EULERIAN CYCLE is also used synonymously with Eulerian circuit. For technical reasons, Eulerian circuits are easier to study mathematically than are HAMILTONIAN CIRCUITS. As a generalization of the KÖNIGSBERG BRIDGE PROBLEM, Euler showed (without proof) that a CONNECTED GRAPH has an Eulerian circuit IFF it has no VERTICES of ODD DEGREE.

FLEURY'S ALGORITHM is an elegant, but inefficient, method of generating Eulerian circuit. An Eulerian cycle of a graph may be found using `EulerianCycle[g]` in the *Mathematica* add-on package `DiscreteMath'Combinatorica'` (which can be loaded with the command `<<DiscreteMath'`).

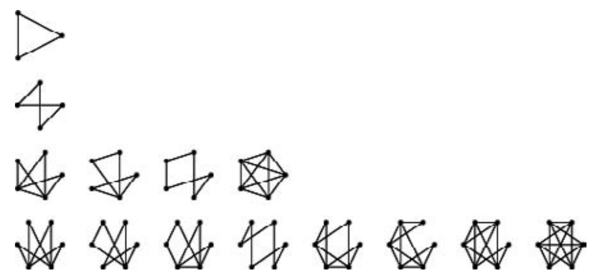
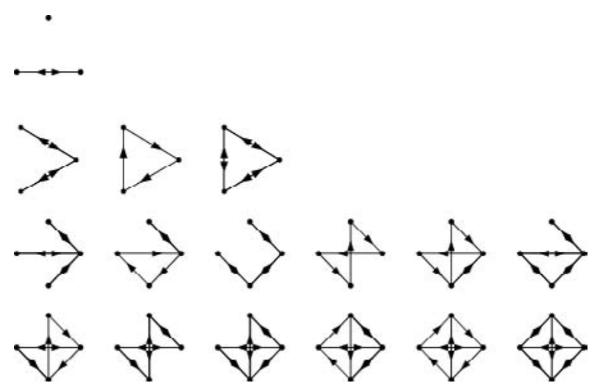
Eulerian Cycle



EULERIAN CIRCUIT

Eulerian Graph



A GRAPH containing an EULERIAN CIRCUIT. Finding the largest SUBGRAPH of graph having an odd number of vertices which is Eulerian is an NP-COMPLETE PROBLEM (Skiena 1990, p. 194).

An UNDIRECTED GRAPH is Eulerian IFF every VERTEX has EVEN DEGREE. The numbers of Eulerian graphs with $n = 1, 2, \ldots$ nodes are 1, 1, 2, 3, 7, 16, 54, 243, ... (Sloane's A002854; Robinson 1969; Mallows and Sloane 1975; Buekenhout 1995, p. 881; Colbourn and Dinitz 1996, p. 687). There is an explicit formula giving these numbers.

Euler showed (without proof) that a CONNECTED GRAPH is Eulerian IFF it has no VERTICES of ODD DEGREE. The numbers of connected Eulerian graphs with $n = 1, 2, \ldots$ nodes are 1, 0, 1, 1, 4, 8, 37, 184, ... (Sloane's A003049; Robinson 1969; Liskovec 1972; Harary and Palmer 1973, p. 117).

A DIRECTED GRAPH is Eulerian IFF every VERTEX has equal INDEGREE and OUTDEGREE. A planar BIPARTITE GRAPH is DUAL to a PLANAR Eulerian graph and vice versa. The numbers of Eulerian digraphs on $n = 1, 2, \ldots$ nodes are 1, 1, 3, 12, ...

Eulerian Integral of the First Kind

Legendre and Whittaker and Watson's (1990) term for the BETA INTEGRAL

$$\int_0^1 x^p(1-x)^q\,dx,$$

whose solution is the BETA FUNCTION $B(p+1,\ q+1)$.

See also BETA FUNCTION, BETA INTEGRAL, EULERIAN INTEGRAL OF THE SECOND KIND

References

Whittaker, E. T. and Watson, G. N. *A Course in Modern Analysis, 4th ed.* Cambridge, England: Cambridge University Press, 1990.

Eulerian Integral of the Second Kind

For $\Re[n] > -1$ and $\Re[z] > 0$,

$$\prod(z,\ n) = n^z \int_0^1 (1-x)^n x^{z-1}\,dx \tag{1}$$

$$= \frac{n!}{(z)_{n+1}}\, n^z \tag{2}$$

$$= B(z,\ n+1), \tag{3}$$

where $(z)_n$ is the POCHHAMMER SYMBOL and $B(p,\ q)$ is the BETA FUNCTION.

See also BETA FUNCTION, BETA INTEGRAL, EULERIAN INTEGRAL OF THE FIRST KIND

Eulerian Number

The number of PERMUTATION RUNS of length n with $k \leq n$, denoted $\left\langle {n \atop k} \right\rangle$, $A_{n,\,k}$, or $A(n,\ k)$. The Eulerian numbers are given explicitly by the sum

$$\left\langle {n \atop k} \right\rangle = \sum_{j=0}^{k} (-1)^j \binom{n+1}{j} (k-j)^n. \tag{1}$$

Making the definition

$$b_{n,\,1} = 1 \tag{2}$$

$$b_{1,\,n} = 1 \tag{3}$$

together with the RECURRENCE RELATION

$$b_{n,\,k} = nb_{n,\,k-1} + kb_{n-1,\,k} \tag{4}$$

for $n > k$ then gives

$$\left\langle {n \atop k} \right\rangle = b_{k,\,n-k+1}. \tag{5}$$

The arrangement of the numbers into a triangle gives EULER'S TRIANGLE, whose entries are 1, 1, 1, 1, 4, 1, 1, 11, 11, 1, ... (Sloane's A008292). Therefore, they represent a sort of generalization of the BINOMIAL COEFFICIENTS where the defining RECURRENCE RELATION weights the sum of neighbors by their row and column numbers, respectively.

The Eulerian numbers satisfy

$$\sum_{k=1}^{n} \left\langle {n \atop k} \right\rangle = n!. \tag{6}$$

Eulerian numbers also arise in the surprising context of integrating the SINC FUNCTION, and also in sums of the form

$$\sum_{k=1}^{\infty} k^n r^k = \mathrm{Li}_{-n}(r) = \frac{r}{(1-r)^{n+1}} \sum_{i=1}^{n} \left\langle {n \atop k} \right\rangle r^{n-i}, \tag{7}$$

where $\mathrm{Li}_m(z)$ is the POLYLOGARITHM function.

Euler-Jacobi Pseudoprime

An Euler-Jacobi pseudoprime to a base a is an ODD COMPOSITE numbers such that $(a, n)=1$ and the JACOBI SYMBOL (a/n) satisfies

$$\left(\frac{a}{n}\right) \equiv a^{(n-1)/2} \pmod n.$$

(Guy 1994; but note that Guy calls these simply "Euler pseudoprimes"). No ODD COMPOSITE number is an Euler-Jacobi pseudoprime for all bases a RELATIVELY PRIME to it. This class includes some CARMICHAEL NUMBERS, all STRONG PSEUDOPRIMES to base a, and all EULER PSEUDOPRIMES to base a. An Euler pseudoprime is pseudoprime to at most 1/2 of all possible bases less than itself.

The first few base-2 Euler-Jacobi pseudoprimes are 561, 1105, 1729, 1905, 2047, 2465, ... (Sloane's A047713), and the first few base-3 Euler-Jacobi pseudoprimes are 121, 703, 1729, 1891, 2821, 3281, 7381, ... (Sloane's A048950). The number of base-2 Euler-Jacobi primes less than 10^2, 10^3, ... are 0, 1, 12, 36, 114, ... (Sloane's A055551).

Euler-Lagrange Derivative

The derivative

$$\frac{\delta L}{\delta q} \equiv \frac{\partial L}{\partial q} - \frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}}\right)$$

appearing in the EULER-LAGRANGE DIFFERENTIAL EQUATION.

Euler-Lagrange Differential Equation

A fundamental equation of CALCULUS OF VARIATIONS which states that if J is defined by an INTEGRAL OF THE FORM

$$J = \int f(x,\ y,\ \dot{y})\,dx, \tag{1}$$

where

$$\dot{y} \equiv \frac{dy}{dt}, \tag{2}$$

then J has a STATIONARY VALUE if the Euler-Lagrange differential equation

$$\frac{\partial f}{\partial y} - \frac{d}{dt}\left(\frac{\partial f}{\partial \dot{y}}\right) = 0 \tag{3}$$

is satisfied. If time DERIVATIVE NOTATION is replaced instead by space variable notation, the equation becomes

$$\frac{\partial f}{\partial y} - \frac{d}{dx}\frac{\partial f}{\partial y_x} = 0. \tag{4}$$

In many physical problems, f_x (the PARTIAL DERIVA-

TIVE of f with respect to x) turns out to be 0, in which case a manipulation of the Euler-Lagrange differential equation reduces to the greatly simplified and partially integrated form known as the BELTRAMI IDENTITY,

$$f - y_x \frac{\partial f}{\partial y_x} = C. \tag{5}$$

For three independent variables (Arfken 1985, pp. 924–44), the equation generalizes to

$$\frac{\partial f}{\partial u} - \frac{\partial}{\partial x}\frac{\partial f}{\partial u_x} - \frac{\partial}{\partial y}\frac{\partial f}{\partial u_y} - \frac{\partial}{\partial z}\frac{\partial f}{\partial u_z} = 0. \tag{6}$$

Problems in the CALCULUS OF VARIATIONS often can be solved by solution of the appropriate Euler-Lagrange equation.

To derive the Euler-Lagrange differential equation, examine

$$\delta J \equiv \delta \int L(q, \dot q, t)\, dt = \int \left(\frac{\partial L}{\partial q}\,\delta q + \frac{\partial L}{\partial \dot q}\,\delta \dot q\right) dt$$

$$= \int \left[\frac{\partial L}{\partial q}\,\delta q + \frac{\partial L}{\partial \dot q}\,\frac{d(\delta q)}{dt}\right] dt, \tag{7}$$

since $\delta \dot q = d(\delta q)/dt$. Now, integrate the second term by PARTS using

$$u = \frac{\partial L}{\partial \dot q} \qquad dv = d(\delta q) \tag{8}$$

$$du = \frac{d}{dt}\left(\frac{\partial L}{\partial \dot q}\right) dt \qquad v = \delta q, \tag{9}$$

so

$$\int \frac{\partial L}{\partial \dot q}\,\frac{d(\delta q)}{dt}\, dt = \int \frac{\partial L}{\partial \dot q}\, d(\delta q)$$

$$= \left[\frac{\partial L}{\partial \dot q}\,\delta q\right]_{t_1}^{t_2} - \int_{t_1}^{t_2} \left(\frac{d}{dt}\frac{\partial L}{\partial \dot q}\, dt\right) \delta q. \tag{10}$$

Combining (7) and (10) then gives

$$\delta J = \left[\frac{\partial L}{\partial \dot q}\,\delta q\right]_{t_1}^{t_2} + \int_{t_1}^{t_2} \left(\frac{\partial L}{\partial q} - \frac{d}{dt}\frac{\partial L}{\partial \dot q}\right) \delta q\, dt. \tag{11}$$

But we are varying the path only, not the endpoints, so $\delta q(t_1) = \delta q(t_2) = 0$ and (11) becomes

$$\delta J = \int_{t_1}^{t_2} \left(\frac{\partial L}{\partial q} - \frac{d}{dt}\frac{\partial L}{\partial \dot q}\right) \delta q\, dt. \tag{12}$$

We are finding the STATIONARY VALUES such that $\delta J = 0$. These must vanish for any small change δq, which gives from (12),

$$\frac{\partial L}{\partial q} - \frac{d}{dt}\left(\frac{\partial L}{\partial \dot q}\right) = 0. \tag{13}$$

This is the Euler-Lagrange differential equation.

The variation in J can also be written in terms of the parameter κ as

$$\delta J = \int [f(x,\ y + \kappa v,\ \dot y + \kappa \dot v) - f(x,\ y,\ \dot y)]\, dt$$

$$= \kappa I_1 + \tfrac{1}{2}\kappa^2 I_2 + \tfrac{1}{6}\kappa^3 I_3 + \tfrac{1}{24}\kappa^4 I_4 + \ldots, \tag{14}$$

where

$$v = \delta y \tag{15}$$

$$\dot v = \delta \dot y \tag{16}$$

and the first, second, etc., variations are

$$I_1 = \int (v f_y + \dot v f_{\dot y})\, dt \tag{17}$$

$$I_2 = \int (v^2 f_{yy} + 2 v \dot v f_{y\dot y} + \dot v^2 f_{\dot y \dot y})\, dt \tag{18}$$

$$I_3 = \int (v^3 f_{yyy} + 3 v^2 \dot v f_{yy\dot y} + 3 v \dot v^2 f_{y\dot y\dot y} + \dot v^3 f_{\dot y\dot y\dot y})\, dt \tag{19}$$

$$I_4 = \int (v^4 f_{yyyy} + 4 v^3 \dot v f_{yyy\dot y} + 6 v^2 \dot v^2 f_{yy\dot y\dot y} + 4 v \dot v^3 f_{y\dot y\dot y\dot y}$$
$$+ \dot v^4 f_{\dot y\dot y\dot y\dot y})\, dt. \tag{20}$$

The second variation can be re-expressed using

$$\frac{d}{dt}(v^2 \lambda) = v^2 \dot\lambda + 2 v \dot v \lambda, \tag{21}$$

so

$$I_2 + [v^2 \lambda]_2^1 = \int_1^2 [v^2(f_{yy} + \dot\lambda) + 2 v \dot v (f_{y\dot y} + \lambda) + \dot v^2 f_{\dot y\dot y}]\, dt. \tag{22}$$

But

$$[v^2 \lambda]_2^1 = 0. \tag{23}$$

Now choose λ such that

$$f_{\dot y\dot y}(f_{yy} + \dot\lambda) = (f_{y\dot y} + \lambda)^2 \tag{24}$$

and z such that

$$f_{y\dot y} + \lambda = -\frac{f_{\dot y\dot y}}{z}\frac{dz}{dt} \tag{25}$$

so that z satisfies

$$f_{\dot y\dot y}\ddot z + \dot f_{\dot y\dot y}\dot z - (f_{yy} - \dot f_{y\dot y}) z = 0. \tag{26}$$

It then follows that

$$I_2 = \int f_{\dot y \dot y}\left(\dot v + \frac{f_{y\dot y} + \lambda}{f_{\dot y \dot y} v}\right)^2 dt = \int f_{\dot y \dot y}\left(\dot v - \frac{v}{z}\frac{dz}{dt}\right)^2. \quad (27)$$

Euler-Lucas Pseudoprime

Let $U(P, Q)$ and $V(P, Q)$ be Lucas sequences generated by P and Q, and define

$$D \equiv P^2 - 4Q.$$

Then

$$\begin{cases} U_{(n-(D/n))/2} \equiv 0 \pmod{n} & \text{when } (Q/n) = 1 \\ V_{(n-(D/n))/2} \equiv D \pmod{n} & \text{when } (Q/n) = -1, \end{cases}$$

where (Q/n) is the Legendre symbol. An odd composite number n such that $(n, QD) = 1$ (i.e., n and QD are relatively prime) is called an Euler-Lucas pseudoprime with parameters (P, Q).

Euler-Maclaurin Integration Formulas

The Euler-Maclaurin integration and sums formulas can be derived from Darboux's formula by substituting the Bernoulli polynomial $B_n(t)$ in for the function $\phi(t)$. Differentiating the identity

$$B_n(t+1) - B_n(t) = nt^{n-1} \quad (1)$$

$n-k$ times gives

$$B_n^{(n-k)}(t+1) - \phi_n^{(n-k)}(t) = n(n-1)\cdots kt^{k-1}. \quad (2)$$

Plugging in $t=0$ gives $B_n^{(n-k)}(1) = B_n^{(n-k)}(0)$. From the Maclaurin series of $B_n(z)$ with $k > 0$, we have

$$B_n^{(n-2k-1)}(0) = 0 \quad (3)$$

$$B_n^{(n-2k)}(0) = \frac{n!}{(2k)!} B_{2k} \quad (4)$$

$$B_n^{(n-1)}(0) = \tfrac{1}{2} n! \quad (5)$$

$$B_n^{(n)}(0) = n!, \quad (6)$$

where B_n is a Bernoulli number, and substituting these values of $B_n^{(n-k)}(1)$ and $B_n^{(n-k)}(0)$ into Darboux's formula gives

$$(z-a)f'(a) = f(z) - f(a) - \frac{z-a}{2}[f'(z) - f'(a)]$$
$$+ \sum_{m=1}^{n-1} \frac{B_{2m}(z-a)^{2m}}{(2m)!}[f^{(2m)}(z) - f^{(2m)}(a)]$$
$$- \frac{(z-a)^{2n+1}}{(2n)!}\int_0^1 B_{2n}(t) f^{(2n+1)}[a-(z-a)t]\,dt, \quad (7)$$

which is the Euler-Maclaurin integration formula (Whittaker and Watson 1990, p. 128).

In certain cases, the last term tends to 0 as $n \to \infty$, and an infinite series can then be obtained for $f(z) - f(a)$. In such cases, sums may be converted to integrals by inverting the formula to obtain the Euler-Maclaurin sum formula

$$\sum_{k=1}^{n-1} f_k = \int_0^n f(k)dk - \tfrac{1}{2}[f(0) + f(n)]$$
$$+ \sum_{k=1}^{\infty} \frac{B_{2n}}{(2n)!}[f^{(2n-1)}(n) - f^{(2n-1)}(0)], \quad (8)$$

which, when expanded, gives

$$\sum_{k=1}^{n-1} f_k = \int_0^n f(k)\,dk - \tfrac{1}{2}[f(0) + f(n)] + \tfrac{1}{12}[f'(n) - f'(0)]$$
$$- \tfrac{1}{720}[f'''(n) - f'''(0)] + \tfrac{1}{30240}[f^{(5)}(n) - f^{(5)}(0)]$$
$$- \tfrac{1}{1209600}[f^{(7)} - f^{(7)}(0)] + \ldots \quad (9)$$

(Abramowitz and Stegun 1972, p. 16). The Euler-Maclaurin sum formula is implemented in *Mathematica* as the function `NSum` with option `Method->Integrate`.

The second Euler-Maclaurin integration formula is used when $f(x)$ is tabulated at n values $f_{3/2}, f_{5/2}, \ldots, f_{n-1/2}$:

$$\int_{x_1}^{x_n} f(x)\,dx = h[f_{3/2} + f_{5/2} + f_{7/2} + \ldots + f_{n-3/2} + f_{n-1/2}]$$
$$- \sum_{k=1}^{\infty} \frac{B_{2k}h^{2k}}{(2k)!}(1 - 2^{-2k+1})[f_n^{(2k-1)} - f_1^{(2k-1)}]. \quad (10)$$

Euler-Maclaurin Sum Formula

EULER-MACLAURIN INTEGRATION FORMULAS

Euler-Mascheroni Constant

The Euler-Mascheroni constant is denoted γ (or sometimes C) and has the numerical value

$$\gamma \approx 0.577215664901532860606512090082402431042\ldots \quad (1)$$

(Sloane's A001620). The Euler-Mascheroni constant was denoted γ and calculated to 16 digits by Euler in 1781. It is therefore sometimes known as Euler's constant. No quadratically converging algorithm for computing γ is known (Bailey 1988). X. Gourdon and P. Demichel computed a record 108 million digits of γ in October 1999 (Gourdon and Sebah).

The Euler-Mascheroni constant is implemented in *Mathematica* as `EulerGamma`. It is not known if this constant is IRRATIONAL, let alone TRANSCENDENTAL (Wells 1986, p. 28). If γ is a simple fraction a/b, then it is known that $b > 10^{10,000}$ (Brent 1977; Wells 1986, p. 28). Conway and Guy (1996) are "prepared to bet that it is transcendental," although they do not expect a proof to be achieved within their lifetimes.

The CONTINUED FRACTION of the Euler-Mascheroni constant is [0, 1, 1, 2, 1, 2, 1, 4, 3, 13, 5, 1, 1, 8, 1, 2, 4, 1, 1, 40, ...] (Sloane's A002852). The first few CONVERGENTS are 1, 1/2, 3/5, 4/7, 11/19, 15/26, 71/123, 228/395, 3035/5258, 15403/26685, ... (Sloane's A046114 and A046115). The positions at which the digits 1, 2, ... first occur in the CONTINUED FRACTION are 2, 4, 9, 8, 11, 69, 24, 14, 139, 52, 22, ... (Sloane's A033149). The sequence of largest terms in the CONTINUED FRACTION is 1, 2, 4, 13, 40, 49, 65, 399, 2076, ... (Sloane's A033091), which occur at positions 2, 4, 8, 10, 20, 31, 34, 40, 529, ... (Sloane's A033092).

The Euler-Mascheroni constant arises in many integrals

$$\gamma \equiv -\int_0^\infty e^{-x}\ln x\,dx \quad (2)$$

$$= \int_0^\infty \left(\frac{1}{1-e^{-x}} - \frac{1}{x}\right)e^{-x}\,dx \quad (3)$$

$$= \int_0^\infty \frac{1}{x}\left(\frac{1}{1+x} - e^{-x}\right)dx \quad (4)$$

(Whittaker and Watson 1990, p. 246), and sums

$$\gamma \equiv 1 + \sum_{k=2}^\infty \left[\frac{1}{k} + \ln\left(\frac{k-1}{k}\right)\right] \quad (5)$$

$$= \lim_{n\to\infty}(H_n - \ln n) \quad (6)$$

$$= \sum_{n=2}^\infty (-1)^n \frac{\zeta(n)}{n} \quad (7)$$

$$= \ln\left(\frac{4}{\pi}\right) - \sum_{n=1}^\infty \frac{(-1)^n \zeta(n+1)}{2^n(n+1)}, \quad (8)$$

where H_n is a HARMONIC NUMBER (Graham *et al.* 1994, p. 278) and $\zeta(z)$ is the RIEMANN ZETA FUNCTION.

γ is also given by the EULER PRODUCT

$$e^\gamma = \lim_{n\to\infty} \frac{1}{\ln n} \prod_{i=1}^n \frac{1}{1 - \frac{1}{pi}}, \quad (9)$$

where the product is over PRIMES p. Another connection with the PRIMES was provided by Dirichlet's 1838 proof that the average number of DIVISORS of all numbers from 1 to n is asymptotic to

$$\frac{\sum_{i=1}^n \sigma_0(i)}{n} \sim \ln n + 2\gamma - 1 \quad (10)$$

(Conway and Guy 1996). de la Vallée Poussin (1898) proved that, if a large number n is divided by all PRIMES $\leq n$, then the average amount by which the QUOTIENT is less than the next whole number is γ.

INFINITE PRODUCTS involving γ also arise from the BARNES' G-FUNCTION with POSITIVE INTEGER n. The cases $G(2)$ and $G(3)$ give

$$\prod_{n=1}^\infty e^{-1+1/2(n)}\left(1+\frac{1}{n}\right)^n = \frac{e^{1+\gamma/2}}{\sqrt{2\pi}} \quad (11)$$

$$\prod_{n=1}^\infty e^{-2+2/n}\left(1+\frac{2}{n}\right)^n = \frac{e^{3+2\gamma}}{\sqrt{2\pi}}. \quad (12)$$

The Euler-Mascheroni constant is also given by the limits

$$\gamma = -\Gamma'(1) \tag{13}$$

(Whittaker and Watson 1990, p. 236),

$$\gamma = \lim_{s \to 1} \zeta(s) - \frac{1}{s-1} \tag{14}$$

(Whittaker and Watson 1990, p. 271), and

$$\gamma = \lim_{x \to \infty} \left[x - \Gamma\left(\frac{1}{x}\right) \right] \tag{15}$$

(Le Lionnais 1983).

The difference between the nth convergent in (6) and γ is given by

$$\sum_{k=1}^{n} \frac{1}{k} - \ln n - \gamma = \int_{n}^{\infty} \frac{x - \lfloor x \rfloor}{x^2}\, dx, \tag{16}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION, and satisfies the INEQUALITY

$$\frac{1}{2(n+1)} < \sum_{k=1}^{n} \frac{1}{k} - \ln n - \gamma < \frac{1}{2n} \tag{17}$$

(Young 1991). A series with accelerated convergence is

$$\gamma = \tfrac{3}{2} - \ln 2 - \sum_{m=2}^{\infty} (-1)^m \frac{m-1}{m} [\zeta(m) - 1] \tag{18}$$

(Flajolet and Vardi 1996). Another series is

$$\gamma = \sum_{n=1}^{\infty} (-1)^n \frac{\lfloor \lg n \rfloor}{n} \tag{19}$$

(Vacca 1910, Gerst 1969), where LG is the LOGARITHM to base 2. The convergence of this series can be greatly improved using Euler's CONVERGENCE IMPROVEMENT transformation to

$$\gamma = \sum_{k=1}^{\infty} 2^{-(k+1)} \sum_{j=0}^{k-1} \frac{1}{\binom{2^{k-j}+j}{j}}, \tag{20}$$

where $\binom{a}{b}$ is a BINOMIAL COEFFICIENT (Beeler *et al.* 1972, with $k-j$ replacing the undefined i). Bailey (1988) gives

$$\gamma = \frac{2^n}{e^{2n}} \sum_{m=0}^{\infty} \frac{2^{mn}}{(m+1)!} \sum_{t=0}^{m} \frac{1}{t+1} - n \ln 2 + \mathcal{O}\left(\frac{1}{2^n e^{2n}}\right), \tag{21}$$

which is an improvement over Sweeney (1963).

The symbol γ is sometimes also used for

$$\gamma' \equiv e^{\gamma} \approx 1.781072 \tag{22}$$

(Gradshteyn and Ryzhik 2000, p. xxvii).

Odena (1982–983) gave the strange approximation

$$(0.11111111)^{1/4} = 0.577350\ldots, \tag{23}$$

and Castellanos (1988) gave

$$(\tfrac{7}{83})^{2/9} = 0.57721521\ldots \tag{24}$$

$$\left(\frac{520^2 + 22}{52^4}\right)^{1/6} = 0.5772156634\ldots \tag{25}$$

$$\left(\frac{80^3 + 92}{61^4}\right)^{1/6} = 0.57721566457\ldots \tag{26}$$

$$\frac{990^3 - 55^3 - 79^2 - 4^2}{70^5} = 0.5772156649015295\ldots. \tag{27}$$

Euler-Mascheroni Integrals

Define

$$I_n \equiv (-1)^n \int_0^\infty (\ln z)^n e^{-z}\, dz, \tag{1}$$

then

$$I_0 = \int_0^\infty e^{-z}\, dz = [-e^{-z}]_0^\infty = (0+1) = 1 \tag{2}$$

$$I_1 = -\int_0^\infty (\ln z) e^{-z}\, dz = \gamma \tag{3}$$

$$I_2 = \gamma^2 + \tfrac{1}{6}\pi^2 \tag{4}$$

$$I_3 = \gamma^3 + \tfrac{1}{2}\gamma\pi^2 + 2\zeta(3) \tag{5}$$

$$I_4 = \gamma^4 + \gamma^2\pi^2 - \tfrac{3}{20}\pi^4 + 8\gamma\zeta(3), \tag{6}$$

where γ is the EULER-MASCHERONI CONSTANT and $\zeta(3)$ is APÉRY'S CONSTANT.

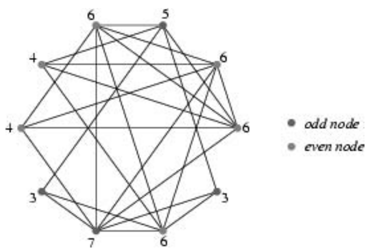
Even Divisor Function

The sum of powers of EVEN DIVISORS of a number. It is the analog of the DIVISOR FUNCTION for even divisors only and is written $\sigma_k^{(e)}(n)$. It is given simply in terms of the usual DIVISOR FUNCTION by



$$\sigma_k^{(e)}(n) = \begin{cases} 0 & \text{for } n \text{ odd} \\ 2^k \sigma_k(n/2) & \text{for } n \text{ even.} \end{cases}$$

See also Divisor Function, Odd Divisor Function

Even Function

A function $f(x)$ such that $f(x) = f(-x)$. An even function times an odd function is odd.

Even Node

A node in a graph is said to be an even node if its vertex degree is even.

See also Graph, Node (Graph), Odd Node, Vertex Degree

Even Number

An integer of the form $N = 2n$, where n is an integer. The even numbers are therefore ..., -4, -2, 0, 2, 4, 6, 8, 10, ... (Sloane's A005843). Since the even numbers are integrally divisible by two, $N \equiv 0 \pmod 2$ for even N. An even number N for which $N \equiv 2 \pmod 4$ is called a singly even number, and an even number N for which $N \equiv 0 \pmod 4$ is called a doubly even number. An integer which is not even is called an odd number. The generating function of the even numbers is

$$\frac{2x}{(x-1)^2} = 2x + 4x^2 + 6x^3 + 8x^4 + \ldots.$$

Even Part

The even part $\text{Ev}(n)$ of a positive integer n is defined by

$$\text{Ev}(n) = 2^{b(n)},$$

where $b(n)$ is the exponent of the exact power of 2 dividing n. The values for $n = 1, 2, ...$, are 1, 2, 1, 4, 1, 2, 1, 8, 1, 2, 1, ... (Sloane's A006519). The even part function can be implemented in *Mathematica* as

```
EvenPart[0]:=1
  EvenPart[n_Integer]:=2^IntegerExponent[n,2]
```

Even Prime

The unique even prime number 2. All other primes are odd primes.

The sequence 2, 4, 6, 10, 14, 22, 26, 34, 38, ... (Sloane's A001747) consisting of the number 2 together with the primes multiplied by 2 is sometimes also called the even primes, since these are the even numbers $n = 2k$ that are divisible by just 1, 2, k, and $2k$.

Event

An event is a certain subset of a probability space. Events are therefore collections of outcomes on which probabilities have been assigned. Events are sometimes assumed to form a Borel field (Papoulis 1984, p. 29).

Eventually Periodic

A PERIODIC SEQUENCE such as $\{1, 1, 1, 2, 1, 2, 1, 2, 1, 2, 1, 1, 2, 1, \ldots\}$ which is periodic from some point onwards.

See also PERIODIC SEQUENCE

Everett Interpolation

EVERETT'S FORMULA

Everett's Formula

$$f_p = (1-p)f_0 + pf_1 + E_2\delta_0^2 + F_2\delta_1^2 + E_4\delta_0^4 + F_4\delta_1^4 + E_6\delta_0^6 + F_6\delta_1^6 + \ldots, \tag{1}$$

for $p \in [0,\ 1]$, where δ is the CENTRAL DIFFERENCE and

$$E_{2n} \equiv G_{2n} - G_{2n+1} \equiv B_{2n} - B_{2n+1} \tag{2}$$

$$F_{2n} \equiv G_{2n+1} \equiv B_{2n} + B_{2n+1}, \tag{3}$$

where G_k are the COEFFICIENTS from GAUSS'S BACKWARD FORMULA and GAUSS'S FORWARD FORMULA and B_k are the COEFFICIENTS from BESSEL'S FINITE DIFFERENCE FORMULA. The E_ks and F_ks also satisfy

$$E_{2n}(p) = F_{2n}(q) \tag{4}$$

$$F_{2n}(p) = E_{2n}(q), \tag{5}$$

for

$$q \equiv 1 - p. \tag{6}$$

See also BESSEL'S FINITE DIFFERENCE FORMULA

Eversion

A curve on the unit sphere $\mathbb{S}^2$ is an eversion if it has no corners or cusps (but it may be self-intersecting). These properties are guaranteed by requiring that the curve's velocity never vanishes. A mapping $\boldsymbol{\sigma}: \mathbb{S}^1 \to \mathbb{S}^2$ forms an immersion of the CIRCLE into the SPHERE IFF, for all $\theta \in \mathbb{R}$,

$$\left|\frac{d}{d\theta}[\boldsymbol{\sigma}(e^{i\theta})]\right| > 0.$$

Smale (1958) showed it is possible to turn a SPHERE inside out (SPHERE EVERSION) using eversion.

See also SPHERE EVERSION

References

Smale, S. "A Classification of Immersions of the Two-Sphere." *Trans. Amer. Math. Soc.* **90**, 281–90, 1958.

Evolute

An evolute is the locus of centers of curvature (the envelope) of a plane curve's normals. The original curve is then said to be the INVOLUTE of its evolute. Given a plane curve represented parametrically by $(f(t),\ g(t))$, the equation of the evolute is given by

$$x = f - R\sin\tau \tag{1}$$

$$y = g + R\cos\tau, \tag{2}$$

where (x, y) are the coordinates of the running point, R is the RADIUS OF CURVATURE

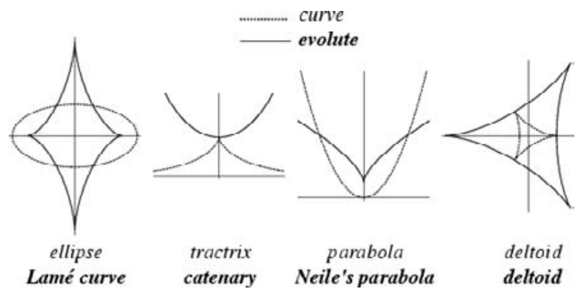
$$R = \frac{(f'^2 + g'^2)^{3/2}}{f'g'' - f''g'}, \tag{3}$$

and τ is the angle between the unit TANGENT VECTOR

$$\hat{\mathbf{T}} = \frac{\mathbf{x}'}{|\mathbf{x}'|} = \frac{1}{\sqrt{f'^2 + g'^2}}\begin{bmatrix} f' \\ g' \end{bmatrix} \tag{4}$$

and the x-AXIS,

$$\cos\tau = \hat{\mathbf{T}} \cdot \hat{\mathbf{x}} \tag{5}$$



$$\sin\tau = \hat{\mathbf{T}} \cdot \hat{\mathbf{y}}. \tag{6}$$

Combining gives

$$x = f - \frac{(f'^2 + g'^2)g'}{f'g'' - f''g'} \tag{7}$$

$$y = g + \frac{(f'^2 + g'^2)f'}{f'g'' - f''g'}. \tag{8}$$

The definition of the evolute of a curve is independent of parameterization for any differentiable function (Gray 1997). If E is the evolute of a curve I, then I is said to be the INVOLUTE of E. The centers of the OSCULATING CIRCLES to a curve form the evolute to that curve (Gray 1997, p. 111).

The following table lists the evolutes of some common curves, some of which are illustrated above.

Curve	Evolute
ASTROID	ASTROID 2 times as large
CARDIOID	CARDIOID 1/3 as large
CAYLEY'S SEXTIC	NEPHROID
CIRCLE	point (0, 0)
CYCLOID	equal CYCLOID
DELTOID	DELTOID 3 times as large
ELLIPSE	ELLIPSE EVOLUTE
EPICYCLOID	enlarged EPICYCLOID
HYPOCYCLOID	similar HYPOCYCLOID
LIMAÇON	CIRCLE CATACAUSTIC for a point source
LOGARITHMIC SPIRAL	equal LOGARITHMIC SPIRAL
NEPHROID	NEPHROID 1/2 as large
PARABOLA	NEILE'S PARABOLA
TRACTRIX	CATENARY

Evolution Strategies

A DIFFERENTIAL EVOLUTION method used to minimize functions of real variables. Evolution strategies are significantly faster at numerical optimization than traditional GENETIC ALGORITHMS and also more likely to find a function's true GLOBAL EXTREMUM.

See also DIFFERENTIAL EVOLUTION, GENETIC ALGORITHM, OPTIMIZATION THEORY

Exact Covering System

A system of congruences a_i mod n_i with $1 \le i \le k$ is called a COVERING SYSTEM if every INTEGER y satisfies $y \equiv a_i \pmod n$ for at least one value of i. A covering system in which each integer is covered by just one congruence is called an exact covering system.

See also COVERING SYSTEM

References

Guy, R. K. "Exact Covering Systems." §F14 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 253–56, 1994.

Exact Differential

A differential OF THE FORM

$$df = P(x, y)\,dx + Q(x, y)\,dy \tag{1}$$

is exact (also called a TOTAL DIFFERENTIAL) if $\int df$ is path-independent. This will be true if

$$df = \frac{\partial f}{\partial x}\,dx + \frac{\partial f}{\partial y}\,dy, \tag{2}$$

so P and Q must be OF THE FORM

$$P(x, y) = \frac{\partial f}{\partial x} \quad Q(x, y) = \frac{\partial f}{\partial y}. \tag{3}$$

But

$$\frac{\partial P}{\partial y} = \frac{\partial^2 f}{\partial y \partial x} \tag{4}$$

$$\frac{\partial Q}{\partial x} = \frac{\partial^2 f}{\partial x \partial y}, \tag{5}$$

so

$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}. \tag{6}$$

See also PFAFFIAN FORM, INEXACT DIFFERENTIAL

Exact Period

LEAST PERIOD

Exact Sequence

An exact sequence is a sequence of maps

$$\alpha_i : A_i \to A_{i+1} \tag{1}$$

between a sequence of spaces A_i, which satisfies

$$\text{im } \alpha_i = \ker \alpha_{i+1}, \tag{2}$$

where "im" denotes the IMAGE and "ker" the KERNEL. That is, for $a \in A_i$, $\alpha_i(a) = 0$ IFF $a = \alpha_{i-1}(b)$ for some $b \in A_{i-1}$. It follows that $\alpha_{i+1} \circ \alpha_i = 0$. The notion of exact sequence makes sense when the spaces are GROUPS, MODULES, CHAIN COMPLEXES, or SHEAVES. The notation for the maps may be suppressed and the sequence written on a single line as

$$\ldots \to A_{i-1} \to A_i \to A_{i+1} \to \ldots. \tag{3}$$

An exact sequence may be of either finite or infinite length. The special case of length five,

$$0 \to A \to B \to C \to 0, \tag{4}$$

beginning and ending with zero, meaning the zero module $\{0\}$, is called a SHORT EXACT SEQUENCE. An infinite exact sequence is called a LONG EXACT SEQUENCE. For example, the sequence where $A_i = \mathbb{Z}/4\mathbb{Z}$ and α_i is given by multiplying by 2,

$$\ldots \overset{\times 2}{\to} \mathbb{Z}/4\mathbb{Z} \overset{\times 2}{\to} \mathbb{Z}/4\mathbb{Z} \overset{\times 2}{\to} \ldots, \tag{5}$$

is a long exact sequence because at each stage the kernel and image are equal to the SUBGROUP $\{0, 2\}$.

Special information is conveyed when one of the spaces A_i is the ZERO MODULE. For instance, the sequence

$$0 \to A \to B \tag{6}$$

is exact IFF the map $A \to B$ is INJECTIVE. Similarly,

$$A \to B \to 0 \tag{7}$$

is exact IFF the map $A \to B$ is SURJECTIVE.

Exact Trilinear Coordinates

The TRILINEAR COORDINATES $\alpha : \beta : \gamma$ of a point P relative to a TRIANGLE are PROPORTIONAL to the directed distances $a' : b' : c'$ from P to the side lines (i.e, $a' = k\alpha$, $b' = k\beta$, $c' = k\gamma$). Letting k be the constant of proportionality,

$$k \equiv \frac{2\Delta}{a\alpha + b\beta + c\gamma},$$

where Δ is the AREA of ΔABC and a, b, and c are the lengths of its sides. When the trilinears are chosen so that $k = 1$, the coordinates are known as exact trilinear coordinates.

See also TRILINEAR COORDINATES

Exactly One

"Exactly one" means "one and only one," sometimes also referred to as "JUST ONE." J. H. Conway has also humorously suggested "onee" (one and only one) by analogy with IFF (if and only if), "twoo" (two and only two), and "threee" (three and only three). This refinement is sometimes needed in formal mathematical discourse because, for example, if you have two apples, you also have one apple, but you do not have *exactly one* apple.

In 2-valued LOGIC, exactly one is equivalent to the exclusive or operator XOR,

$$P(E) \text{ XOR } P(F) = P(E) + P(F) - 2P(E \cap F).$$

See also IFF, PRECISELY UNLESS, XNOR, XOR

Exactly When

IFF

Excenter

The center J_i of an EXCIRCLE. There are three excenters for a given TRIANGLE, denoted J_1, J_2, J_3. The INCENTER I and excenters J_i of a TRIANGLE are an ORTHOCENTRIC SYSTEM.

$$\overline{OI}^2 + \overline{OJ_1}^2 + \overline{OJ_2}^2 + \overline{OJ_3}^2 = 12R^2,$$

where O is the CIRCUMCENTER, J_i are the excenters, and R is the CIRCUMRADIUS (Johnson 1929, p. 190). Denote the MIDPOINTS of the original TRIANGLE M_1, M_2, and M_3. Then the lines J_1M_1, J_2M_2, and J_3M_3 intersect in a point known as the MITTENPUNKT.

See also CENTROID (ORTHOCENTRIC SYSTEM), EXCEN-

TER-EXCENTER CIRCLE, EXCENTRAL TRIANGLE, EXCIRCLE, INCENTER, MITTENPUNKT

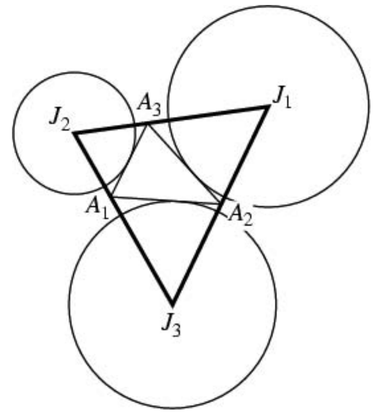
Wells, D. *The Penguin Dictionary of Curious and Interesting Geometry.* London: Penguin, pp. 115–16, 1991.

Excenter-Excenter Circle

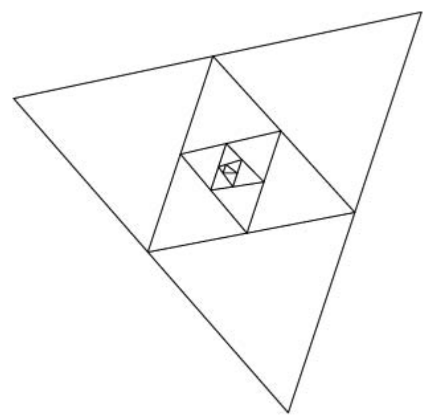
Given a TRIANGLE $\Delta A_1A_2A_3$, the points A_1, I, and J_1 lie on a line, where I is the INCENTER and J_1 is the EXCENTER corresponding to A_1. Furthermore, the circle with J_2J_3 as the diameter has Q as its center, where P is the intersection of A_1J_1 with the CIRCUMCIRCLE of $A_1A_2A_3$ and Q is the point opposite P on the CIRCUMCIRCLE. The circle with diameter J_2J_3 also passes through A_2 and A_3 and has radius

$$r = \tfrac{1}{2} a_1 \csc\left(\tfrac{1}{2}\alpha_1\right) = 2R\cos\left(\tfrac{1}{2}\alpha_1\right).$$



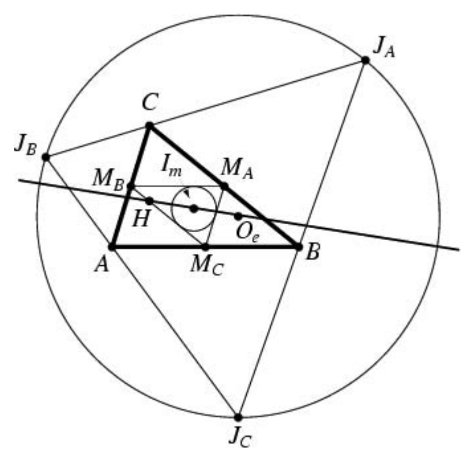
It arises because the points I, J_1, J_2, and J_3 form an ORTHOCENTRIC SYSTEM.

See also EXCENTER, INCENTER-EXCENTER CIRCLE, ORTHOCENTRIC SYSTEM



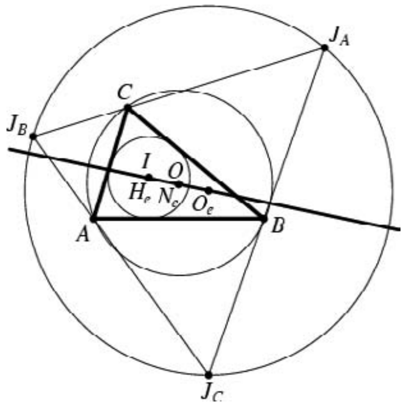
References

Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle.* Boston, MA: Houghton Mifflin, pp. 185–86, 1929.

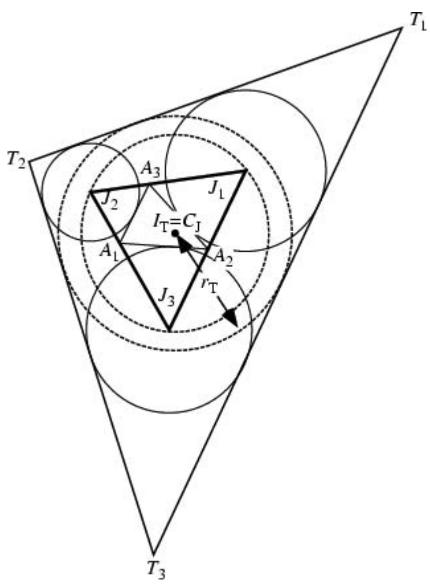


Excentral Triangle

The TRIANGLE $J = \Delta J_1J_2J_3$ with VERTICES corresponding to the EXCENTERS of a given TRIANGLE A, also called the TRITANGENT TRIANGLE.



Beginning with an arbitrary TRIANGLE A, find the excentral triangle J. Then find the excentral triangle J' of that TRIANGLE, and so on. Then the resulting TRIANGLE $J^{(\infty)}$ approaches an EQUILATERAL TRIANGLE.



Given a triangle ΔABC, draw the excentral triangle $\Delta J_AJ_BJ_C$ and MEDIAL TRIANGLE $\Delta M_AM_BM_C$. Then the ORTHOCENTER H of ΔABC, INCENTER I_m of $\Delta M_AM_BM_C$, and CIRCUMCENTER O_e of $\Delta J_AJ_BJ_C$ are

COLLINEAR with I_m the MIDPOINT of HO_e (Honsberger 1995).

The INCENTER I of ΔABC coincides with the ORTHOCENTER H_e of $\Delta J_A J_B J_C$, and the CIRCUMCENTER O of ΔABC coincides with the NINE-POINT CENTER N_e of $\Delta J_A J_B J_C$. Furthermore, $N_e = O$ is the MIDPOINT of the line segment joining the ORTHOCENTER H_e and CIRCUMCENTER O_e of $\Delta J_A J_B J_C$ (Honsberger 1995).

Call T the TRIANGLE tangent externally to the EXCIRCLES of A. Then the INCENTER I_T of K coincides with the CIRCUMCENTER C_J of TRIANGLE $\Delta J_1 J_2 J_3$, where J_i are the EXCENTERS of A. The INRADIUS r_T of the INCIRCLE of T is

$$r_T = 2R + r = \tfrac{1}{2}(r + r_1 + r_2 + r_3),$$

where R is the CIRCUMRADIUS of A, r is the INRADIUS, and r_i are the EXRADII (Johnson 1929, p. 192).

Exceptional Set of Goldbach Numbers

GOLDBACH NUMBER

Excess

The KURTOSIS of a distribution is sometimes called the excess, or excess coefficient. The term is also used to refer to the quantity

$$e \equiv n - f_0(n, g)$$

for a GRAPH G with n vertices and GIRTH g, where

$$f_0(v,\ g) = \begin{cases} \dfrac{v(v-1)^r - 2}{v-2} & \text{for } g = 2r+1 \\ \dfrac{2(v-1)^r - 2}{v-2} & \text{for } g = 2r \end{cases}$$

(Biggs and Ito 1980, Wong 1982). A (v, g)-CAGE GRAPH having $f(v,\ g) = f_0(v,\ g)$ vertices (i.e., the minimal number, so that the excess is $e = 0$) is called a MOORE GRAPH.

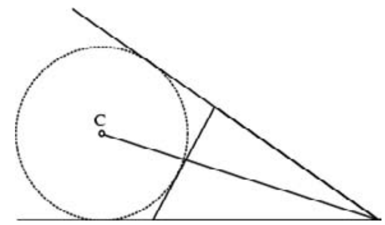
ABUNDANT NUMBER

Exchange Shuffle

A SHUFFLE of a deck of cards obtained by successively exchanging the cards in position 1, 2, ..., n with cards in randomly chosen positions. For $4 \leq n \leq 17$, the most frequent permutation is $(n, \ldots, m+1)(m, \ldots, 1)$, where $m = n/2$ if n is even and either $(n-1)/2$ or $(n+1)/2$ if n is odd (Goldstine and Moews 2000). Amazingly, for $n \geq 18$ cards, the identity permutation (i.e., the original state before the cards were shuffled) is the most likely (Goldstine and Moews 2000).

See also SHUFFLE



References

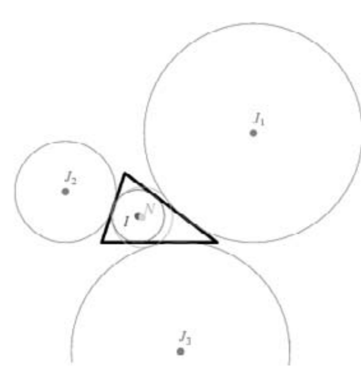
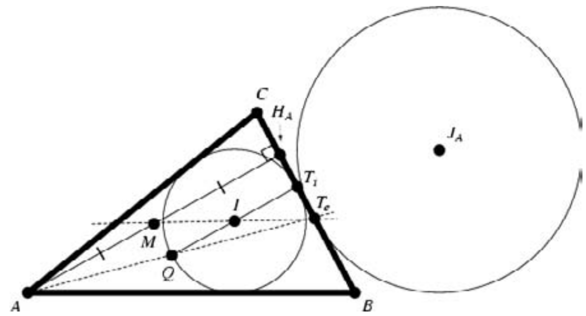
Excircle

Given a TRIANGLE, extend two nonadjacent sides. The CIRCLE tangent to these two lines and to the other side of the TRIANGLE is called an ESCRIBED CIRCLE, or excircle. The CENTER J_i of the excircle is called the EXCENTER and lies on the external ANGLE BISECTOR of the opposite ANGLE. Every TRIANGLE has three excircles, and the TRILINEAR COORDINATES of the EXCENTERS are $-1:1:1$, $1:-1:1$, and $1:1:-1$. The RADIUS r_i of the excircle i is called its EXRADIUS.



Note that the three excircles are *not* necessarily tangent to the INCIRCLE, and so these four circles are not equivalent to the configuration of the SODDY CIRCLES.



Given a TRIANGLE with INRADIUS r, let h_i be the ALTITUDES of the excircles, and r_i their RADII (the EXRADII). Then

$$\frac{1}{h_1} + \frac{1}{h_2} + \frac{1}{h_3} = \frac{1}{r_1} + \frac{1}{r_2} + \frac{1}{r_3} = \frac{1}{r}$$

(Johnson 1929, p. 189).

There are four CIRCLES that are tangent all three sides (or their extensions) of a given TRIANGLE: the INCIRCLE I and three excircles J_1, J_2, and J_3. These four circles are, in turn, all touched by the NINE-POINT CIRCLE N.

Given a TRIANGLE ΔABC, construct the INCIRCLE with INCENTER I and EXCIRCLE with EXCENTER J_A. Let T_i be the tangent point of ΔABC with its incircle, T_e be the tangent point of ΔABC with its EXCIRCLE J_A, H_A the foot of the ALTITUDE to vertex A, M the MIDPOINT of AH_A, and construct Q such that QT_i is a DIAMETER of the INCIRCLE. Then M, I, and T_e are COLLINEAR, as are A, Q, and T_e (Honsberger 1995).

Excision Axiom

One of the EILENBERG-STEENROD AXIOMS which states that, if X is a SPACE with SUBSPACES A and U such that the CLOSURE of A is contained in the interior of U, then the INCLUSION MAP $(X\ U,\ A\ U) \to (X,\ A)$ induces an isomorphism $H_n(X\ U,\ A\ U) \to H_n(X,\ A)$.

Excluded Middle Law

A law in (2-valued) LOGIC which states there is no third alternative to TRUTH or FALSEHOOD. In other words, for any statement A, either A or not-A must be true and the other must be false. This law no longer holds in THREE-VALUED LOGIC or FUZZY LOGIC.

See also BIVALENT, FUZZY LOGIC, THREE-VALUED LOGIC

References

Excludent

A method which can be used to solve any QUADRATIC CONGRUENCE EQUATION. This technique relies on the fact that solving

$$x^2 \equiv b \pmod p$$

is equivalent to finding a value y such that

$$b + py = x^2.$$

Pick a few small moduli m. If y mod m does not make $b+py$ a quadratic residue of m, then this value of y may be excluded. Furthermore, values of $y > p/4$ are never necessary.

See also QUADRATIC CONGRUENCE EQUATION

Excludent Factorization Method

Also known as the difference of squares method. It was first used by Fermat and improved by Gauss. Gauss looked for INTEGERS x and y satisfying

$$y^2 \equiv x^2 - N \pmod E$$

for various moduli E. This allowed the exclusion of many potential factors. This method works best when factors are of approximately the same size, so it is sometimes better to attempt mN for some suitably chosen value of m.

See also PRIME FACTORIZATION ALGORITHMS

Exclusion

METHOD OF EXCLUSIONS

Exclusive Disjunction

A DISJUNCTION that is true if only one, but not both, of its arguments are true, and is false if neither or both are true, which is equivalent to the XOR connective.

By contrast, the INCLUSIVE DISJUNCTION is true if either *or both* of its arguments are true. This is equivalent to the OR CONNECTIVE.

See also DISJUNCTION, INCLUSIVE DISJUNCTION, OR, XOR

Exclusive Nor

XNOR

Exclusive Or
XOR

Excosine Circle
If the tangents at B and C to the CIRCUMCIRCLE of a TRIANGLE ΔABC intersect in a point K_1, then the CIRCLE with center K_1 and which passes through B and C is called the excosine circle, and cuts AB and AC in two points which are extremities of a DIAMETER.

See also COSINE CIRCLE

Exeter Point
Define A' to be the point (other than the VERTEX A) where the MEDIAN through A meets the CIRCUMCIRCLE of ABC, and define B' and C' similarly. Then the Exeter point is the PERSPECTIVE CENTER of the TRIANGLE $A'B'C'$ and the TANGENTIAL TRIANGLE. It has TRIANGLE CENTER FUNCTION

$$\alpha = a(b^4 + c^4 - a^4).$$

Exhaustion Method
The method of exhaustion was a INTEGRAL-like limiting process used by Archimedes to compute the AREA and VOLUME of 2-D LAMINA and 3-D SOLIDS.

See also INTEGRAL, LIMIT

Existence
If at least one solution can be determined for a given problem, a solution to that problem is said to exist. Frequently, mathematicians seek to prove the existence of solutions (the EXISTENCE PROBLEM) and then investigate their UNIQUENESS.

See also EXISTENCE PROBLEM, EXISTS, PICARD'S EXISTENCE THEOREM, UNIQUE

Existence Problem
The question of whether a solution to a given problem exists. The existence problem can be solved in the affirmative without actually finding a solution to the original problem. Such a demonstration is said to be nonconstructive, and is called a NONCONSTRUCTIVE PROOF or an existence proof.

See also ENUMERATION PROBLEM, EXISTENCE, NONCONSTRUCTIVE PROOF, PICARD'S EXISTENCE THEOREM

Exotic Sphere

Milnor (1963) found more than one smooth structure on the 7-D HYPERSPHERE. Generalizations have subsequently been found in other dimensions. Using SURGERY theory, it is possible to relate the number of DIFFEOMORPHISM classes of exotic spheres to higher homotopy groups of spheres (Kosinski 1992).

Kervaire and Milnor (1963) computed a list of the number $N(d)$ of distinct (up to DIFFEOMORPHISM) DIFFERENTIAL STRUCTURES on spheres indexed by the DIMENSION d of the sphere. For $d = 1, 2, \ldots$, assuming the POINCARÉ CONJECTURE, they are 1, 1, 1, ≥ 2, 1, 1, 28, 2, 8, 6, 992, 1, 3, 2, 16256, 2, 16, 16, ... (Sloane's A001676). The status of $d = 4$ is still unresolved: at least one exotic structure exists, but it is not known if others do as well.

The only exotic Euclidean spaces are a CONTINUUM of EXOTIC R4 structures.

Exp

EXPONENTIAL FUNCTION

Expansion

An AFFINE TRANSFORMATION (sometimes called an enlargement or dilation) in which the scale is increased. It is the opposite of a CONTRACTION, and is also sometimes called an enlargement. A CENTRAL DILATION corresponds to an expansion plus a TRANSLATION.

See also AFFINE TRANSFORMATION, CENTRAL DILATION, CONTRACTION (GEOMETRY), DILATION, HOMOTHETIC, TRANSFORMATION

References

Coxeter, H. S. M. and Greitzer, S. L. "Dilation." §4.7 in *Geometry Revisited.* Washington, DC: Math. Assoc. Amer., pp. 94–5, 1967.
Hilbert, D. and Cohn-Vossen, S. *Geometry and the Imagination.* New York: Chelsea, p. 13, 1999.

Expansive

Let ϕ be a MAP. Then ϕ is expansive if the statement that the DISTANCE $d(\phi^n x,\ \phi^n y) < \delta$ for all $n \in \mathbb{Z}$ implies that $x = y$. Equivalently, ϕ is expansive if the orbits of two points x and y are never very close.

Expectation Value

The expectation value of a function $f(x)$ in a variable x is denoted $\langle f(x) \rangle$ or $E\{f(x)\}$. For a single discrete variable, it is defined by

$$\langle f(x) \rangle = \sum_x f(x)P(x). \qquad (1)$$

For a single continuous variable it is defined by,

$$\langle f(x) \rangle = \int f(x)P(x)\, dx. \qquad (2)$$

The expectation value satisfies

$$\langle ax + by \rangle = a\langle x \rangle + b\langle y \rangle \tag{3}$$

$$\langle a \rangle = a \tag{4}$$

$$\left\langle \sum x \right\rangle = \sum \langle x \rangle. \tag{5}$$

For multiple discrete variables

$$\langle f(x_1, \ldots, x_n) \rangle = \sum_{x_1, \ldots, x_n} f(x_1, \ldots, x_n) P(x_1, \ldots, x_n). \tag{6}$$

For multiple continuous variables

$$\langle f(x_1, \ldots, x_n) \rangle = \int f(x_1, \ldots, x_n) P(x_1, \ldots, x_n)\, dx_1 \cdots dx_n. \tag{7}$$

The (multiple) expectation value satisfies

$$\begin{aligned} \langle (x - \mu_x)(y - \mu_y) \rangle &= \langle xy - \mu_x y - \mu_y x + \mu_x \mu_y \rangle \\ &= \langle xy \rangle - \mu_x \mu_y - \mu_y \mu_x + \mu_x \mu_y \\ &= \langle xy \rangle - \langle x \rangle \langle y \rangle, \end{aligned} \tag{8}$$

where μ_i is the MEAN for the variable i.

Expected Value

EXPECTATION VALUE

Experiment

An experiment $E(S, F, P)$ is defined (Papoulis 1984, p. 30) as a mathematical object consisting of the following elements.

1. A set S (the PROBABILITY SPACE) of elements.
2. A BOREL FIELD F consisting of certain subsets of S called EVENTS.
3. A number $P(X)$ satisfying the PROBABILITY AXIOMS, called the probability, that is assigned to every event A.

JEEP PROBLEM

Exponent

The POWER p in an expression a^p.

See also BASE (NUMBER), POWER, EXPONENT LAWS, EXPONENT VECTOR, HAUPT-EXPONENT

Exponent Laws

The laws governing the combination of EXPONENTS (POWERS), sometimes called the laws of indices (Higgens 1998). The laws are given by

$$x^m \cdot x^n = x^{m+n} \tag{1}$$

$$\frac{x^m}{x^n} = x^{m-n} \tag{2}$$

$$(x^m)^n = x^{mn} \tag{3}$$

$$(xy)^m = x^m y^m \tag{4}$$

$$\left(\frac{x}{y}\right)^n = \frac{x^n}{y^n} \tag{5}$$

$$x^{-n} = \frac{1}{x^n} \tag{6}$$

$$\left(\frac{x}{y}\right)^{-n} = \left(\frac{y}{x}\right)^n, \tag{7}$$

where quantities in the DENOMINATOR are taken to be nonzero. Special cases include

$$x^1 = x \tag{8}$$

and

$$x^0 = 1 \tag{9}$$

for $x \neq 0$. The definition $0^0 = 1$ is sometimes used to simplify formulas, but it should be kept in mind that this equality is a definition and not a fundamental mathematical truth.

Exponential

EXPONENTIAL FUNCTION

Exponential Digital Invariant

NARCISSISTIC NUMBER

Exponential Distribution

Given a POISSON DISTRIBUTION with rate of change λ, the distribution of waiting times between successive changes (with $k = 0$) is

$$D(x) \equiv P(X \le x) = 1 - P(X > x)$$

$$= 1 - \frac{(\lambda x)^0 e^{-\lambda x}}{0!} = 1 - e^{-\lambda x} \tag{1}$$

$$P(x) = D'(x) = \lambda e^{-\lambda x}, \tag{2}$$

which is normalized since

$$\int_0^\infty P(x)\, dx = \lambda \int_0^\infty e^{-\lambda x}\, dx$$

$$= -[e^{-\lambda x}]_0^\infty = -(0 - 1) = 1. \tag{3}$$

This is the only MEMORYLESS RANDOM DISTRIBUTION. Define the MEAN waiting time between successive changes as $\theta \equiv \lambda^{-1}$. Then

$$P(x) = \begin{cases} \frac{1}{\theta} e^{-x/\theta} & x \ge 0 \\ 0 & x < 0. \end{cases} \tag{4}$$

The MOMENT-GENERATING FUNCTION is

$$M(t) = \int_0^\infty e^{tx} \left(\frac{1}{\theta}\right) e^{-x/\theta}\, dx = \frac{1}{\theta} \int_0^\infty e^{-(1-\theta t)x/\theta}\, dx$$

$$= \left[\frac{e^{-(1-\theta t)x/\theta}}{1 - \theta t}\right]_0^\infty = \frac{1}{1 - \theta t} \tag{5}$$

$$M'(t) = \frac{\theta}{(1 - \theta t)^2} \tag{6}$$

$$M''(t) = \frac{2\theta^2}{(1 - \theta t)^3}, \tag{7}$$

so

$$R(t) \equiv \ln M(t) = -\ln(1 - \theta t) \tag{8}$$

$$R'(t) = \frac{\theta}{1 - \theta t} \tag{9}$$

$$R''(t) = \frac{\theta^2}{(1 - \theta t)^2} \tag{10}$$

$$\mu = R'(0) = \theta \tag{11}$$

$$\sigma^2 = R''(0) = \theta^2. \tag{12}$$

The CHARACTERISTIC FUNCTION is

$$\phi(t) = \mathcal{F}\{\lambda e^{-\lambda x}[\tfrac{1}{2}(1 + \operatorname{sgn} x)]\} \tag{13}$$

$$= \frac{i\lambda}{t + i\lambda}, \tag{14}$$

where $\mathcal{F}[f]$ is the FOURIER TRANSFORM with parameters $a = b = 1$.
The SKEWNESS and KURTOSIS are given by

$$\gamma_1 = 2 \tag{15}$$

$$\gamma_2 = 6. \tag{16}$$

The MEAN and VARIANCE can also be computed directly

$$\langle x \rangle \equiv \int_0^\infty P(x)\, dx = \frac{1}{s} \int_0^\infty x e^{-x/s}\, dx. \tag{17}$$

Use the integral

$$\int x e^{ax}\, dx = \frac{e^{ax}}{a^2}(ax - 1) \tag{18}$$

to obtain

$$\langle x \rangle = \frac{1}{s} \left[\frac{e^{-x/s}}{\left(-\frac{1}{s}\right)^2} \left\{ \left(-\frac{1}{s}\right) x - 1 \right\} \right]_0^\infty$$

$$= -s\left[e^{-x/s}\left(1+\frac{x}{s}\right)\right]_0^\infty$$

$$= -s(0-1) = s. \quad (19)$$

Now, to find

$$\langle x^2 \rangle = \frac{1}{s}\int_0^\infty x^2 e^{-x/s}\,dx, \quad (20)$$

use the integral

$$\int x^2 e^{-x/s}\,dx = \frac{e^{ax}}{a^3}(2 - 2ax + a^2x^2) \quad (21)$$

$$\langle x^2 \rangle = \frac{1}{s}\left[\frac{e^{-x/s}}{\left(-\frac{1}{s}\right)^3}\left(2+\frac{2}{s}\,x+\frac{1}{s^2}\,x^2\right)\right]_0^\infty$$

$$= -s^2(0-2) = 2s^2, \quad (22)$$

giving

$$\sigma^2 \equiv \langle x^2 \rangle - \langle x \rangle^2$$

$$= 2s^2 - s^2 = s^2 \quad (23)$$

$$\sigma \equiv \sqrt{\operatorname{var}(x)} = s. \quad (24)$$

If a generalized exponential probability function is defined by

$$P_{(\alpha,\ \beta)}(x) = \frac{1}{\beta}\,e^{-(x-\alpha)/\beta}, \quad (25)$$

for $x \geq \alpha$, then the CHARACTERISTIC FUNCTION is

$$\phi(t) = \frac{e^{i\alpha t}}{1 - i\beta t}, \quad (26)$$

and the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \alpha + \beta \quad (27)$$

$$\sigma^2 = \beta^2 \quad (28)$$

$$\gamma_1 = 2 \quad (29)$$

$$\gamma_2 = 6. \quad (30)$$

Exponential Divisor

E-DIVISOR

Exponential Function

The exponential function is defined by

$$\exp(x) \equiv e^x, \quad (1)$$

where *E* is the constant 2.718.... It satisfies the identity

$$\exp(x+y) = \exp(x)\exp(y). \quad (2)$$

If $z \equiv x + iy$,

$$e^z = e^{x+iy} = e^x e^{iy} = e^x(\cos y + i \sin y). \quad (3)$$

The exponential function satisfies the identities

$$e^x = \cosh x + \sinh x \quad (4)$$

$$= \sec(\operatorname{gd} x) + \tan(\operatorname{gd} x) \quad (5)$$

$$= \tan\left(\tfrac{1}{4}\pi + \tfrac{1}{2}\operatorname{gd} x\right) \quad (6)$$

$$= \frac{1 + \sin(\operatorname{gd} x)}{\cos(\operatorname{gd} x)}, \quad (7)$$

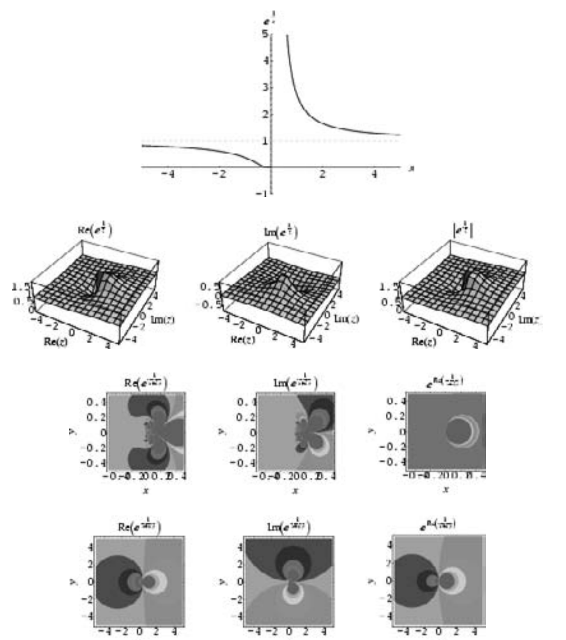
where $\operatorname{gd} x$ is the GUDERMANNIAN FUNCTION (Beyer 1987, p. 164; Zwillinger 1995, p. 485).
The exponential function has MACLAURIN SERIES

$$\exp(x) = \sum_{n=0}^{\infty} \frac{x^n}{n!}, \quad (8)$$

and satisfies the LIMIT

$$\exp(x) = \lim_{n\to\infty}\left(1 + \frac{x}{n}\right)^n. \quad (9)$$

If



$$a + bi = e^{x+iy}, \tag{10}$$

then

$$y = \tan^{-1}\left(\frac{b}{a}\right) \tag{11}$$

$$x = \ln\left\{b \csc\left[\tan^{-1}\left(\frac{b}{a}\right)\right]\right\}$$

$$= \ln\left\{a \sec\left[\tan^{-1}\left(\frac{b}{a}\right)\right]\right\}. \tag{12}$$

The above plot shows the function $e^{1/z}$.

Exponential Generating Function

An exponential generating function for the integer sequence a_0, a_1, ... is a function $E(x)$ such that

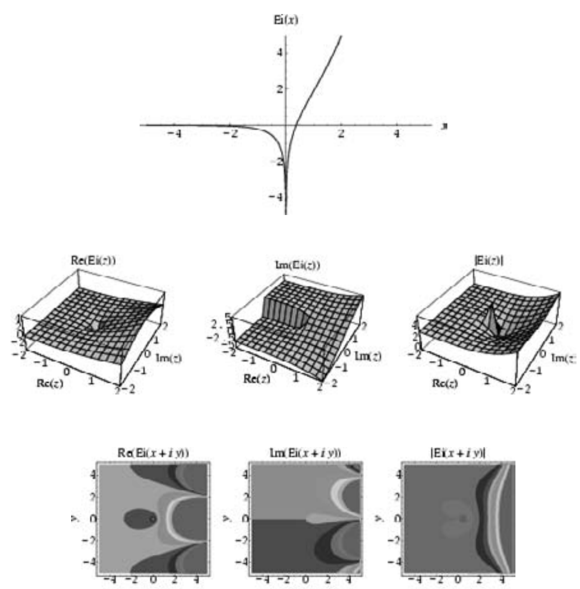
$$E(x) = \sum_{k=0}^{\infty} a_k \frac{x^k}{k!} = a_0 + a_1 \frac{x}{1!} + a_2 \frac{x^2}{2!} + \ldots.$$

See also GENERATING FUNCTION

References

Sloane, N. J. A. and Plouffe, S. *The Encyclopedia of Integer Sequences.* San Diego, CA: Academic Press, p. 9, 1995.

Exponential Inequality



For $c < 1$,

$$x^c < 1 + c(x-1).$$

For $c > 1$,

$$x^c > 1 + c(x-1).$$

Exponential Integral

Let $E_1(x)$ be the *En*-FUNCTION with $n = 1$,

$$E_1(x) \equiv \int_1^{\infty} \frac{e^{-tx}\,dt}{t} = \int_x^{\infty} \frac{e^{-u}\,du}{u}. \tag{1}$$

Then define the exponential integral ei(x) by

$$E_1(x) = -\mathrm{ei}(-x), \tag{2}$$

where the retention of the −ei(−x) NOTATION is a historical artifact. Then ei(x) is given by the integral

$$\mathrm{ei}(x) = -\int_{-x}^{\infty} \frac{e^{-t}\,dt}{t}. \tag{3}$$

This function is given by the *Mathematica* function `ExpIntegralEi[x]`. The exponential integral can also be written

$$\mathrm{ei}(ix) = \mathrm{ci}(x) + i\,\mathrm{si}(x), \tag{4}$$

where ci(x) and si(x) are COSINE and SINE INTEGRAL. The real ROOT of the exponential integral occurs at 0.37250741078..., which is not known to be expressible in terms of other standard constants. The quantity $-e\,\mathrm{ei}(-1) = 0.596347362\ldots$ is known as the GOMPERTZ CONSTANT.

$$\lim_{x\to 0+} \frac{e^{2\mathrm{ei}(-x)}}{x^2} = e^{2\gamma}, \tag{5}$$

where γ is the EULER-MASCHERONI CONSTANT. The TAYLOR SERIES of ei(−x) is given by

$$\mathrm{ei}(-x) = \gamma + i\pi + \ln x - x + \tfrac{1}{4}x^2 - \tfrac{1}{18}x^3 + \tfrac{1}{96}x^4 - \tfrac{1}{600}x^5 + \ldots, \tag{6}$$

where the denominators of the coefficients are given by $n \cdot n!$ (Sloane's A001563; van Heemert 1957, Mundfrom 1994).

Exponential Map

On a LIE GROUP, exp is a MAP from the LIE ALGEBRA to its LIE GROUP. If you think of the LIE ALGEBRA as the TANGENT SPACE to the identity of the LIE GROUP, exp(v) is defined to be h(1), where h is the unique LIE GROUP HOMEOMORPHISM from the REAL NUMBERS to the LIE GROUP such that its velocity at time 0 is v.

On a RIEMANNIAN MANIFOLD, exp is a MAP from the TANGENT BUNDLE of the MANIFOLD to the MANIFOLD, and exp(v) is defined to be h(1), where h is the unique GEODESIC traveling through the base-point of v such that its velocity at time 0 is v.

The three notions of exp (exp from COMPLEX ANALYSIS, exp from LIE GROUPS, and exp from Riemannian geometry) are all linked together, the strongest link being between the LIE GROUPS and Riemannian geometry definition. If G is a compact LIE GROUP, it admits a left and right invariant RIEMANNIAN METRIC. With respect to that metric, the two exp maps agree on their common domain. In other words, one-parameter subgroups are geodesics. In the case of the MANIFOLD $\mathbb{S}^1$, the CIRCLE, if we think of the tangent space to 1 as being the IMAGINARY axis (Y-AXIS) in the COMPLEX PLANE, then

$$\exp_{\text{Riemannian geometry}}(v) = \exp_{\text{Lie Groups}}(v) = \exp_{\text{complex analysis}}(v),$$

and so the three concepts of the exponential all agree in this case.

Exponential Map Matrix

MATRIX EXPONENTIAL

Exponential Matrix

MATRIX EXPONENTIAL

Exponential Polynomial

Polynomials $\phi_n(x)$ (sometimes called the BELL POLY-

NOMIALS) which form the associated SHEFFER SEQUENCE for

$$f(t) = \ln(1 + t), \tag{1}$$

and therefore have GENERATING FUNCTION

$$\sum_{k=0}^{n} \frac{\phi_k(x)}{k!} t^k = e^{(e^t - 1)x}. \tag{2}$$

Additional GENERATING FUNCTIONS are given by

$$\phi_n(x) \equiv e^{-x} \sum_{k=0}^{\infty} \frac{k^n x^k}{k!} \tag{3}$$

or

$$\phi_n(x) = x \sum_{k=1}^{n} \binom{n-1}{k-1} \phi_{k-1}(x), \tag{4}$$

with $\phi_0(x) = 1$, where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT. The exponential polynomials have the explicit formula

$$\phi_n(x) = \sum_{k=0}^{n} S(n, k) x^k, \tag{5}$$

where $S(n, k)$ is a STIRLING NUMBER OF THE SECOND KIND. The binomial identity

$$\phi_n(x + y) = \sum_{k=0}^{n} \binom{n}{k} \phi_k(x) \phi_{n-k}(y), \tag{6}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, and the recurrence formula is

$$\phi_{n+1}(x) = x[\phi_n(x) + \phi_n'(x)]. \tag{7}$$

The Bell polynomials are defined such that $\phi_n(1) = B_n$, where B_n is a BELL NUMBER. The first few Bell polynomials are

$$\phi_0(x) = 1$$

$$\phi_1(x) = x$$

$$\phi_2(x) = x + x^2$$

$$\phi_3(x) = x + 3x^2 + x^3$$

$$\phi_4(x) = x + 7x^2 + 6x^3 + x^4$$

$$\phi_5(x) = x + 15x^2 + 25x^3 + 10x^4 + x^5$$

$$\phi_6(x) = x + 31x^2 + 90x^3 + 65x^4 + 15x^5 + x^6.$$

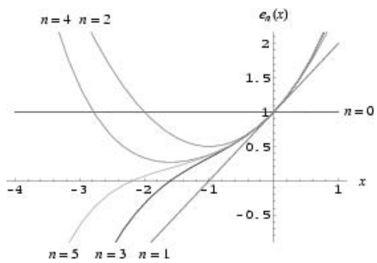
Exponential Sum Formulas

$$\sum_{n=0}^{N-1} e^{inx} = \frac{1 - e^{iNx}}{1 - e^{ix}} = \frac{-e^{iNx/2}(e^{-iNx/2} - e^{iNx/2})}{-e^{ix/2}(e^{-ix/2} - e^{ix/2})}$$

$$= \frac{\sin\left(\frac{1}{2} Nx\right)}{\sin\left(\frac{1}{2} x\right)} e^{ix(N-1)/2}, \tag{1}$$

where

$$\sum_{n=0}^{N-1} r^n = \frac{1 - r^N}{1 - r} \tag{2}$$



has been used. Similarly,

$$\sum_{n=0}^{N-1} p^n e^{inx} = \frac{1-p^N e^{iNx}}{1-pe^{ix}} \tag{3}$$

$$\sum_{n=0}^{\infty} p^n e^{inx} = \frac{1}{e^{ipx}-1} = \frac{1-pe^{-ix}}{1-2p\cos x+p^2}. \tag{4}$$

By looking at the REAL and IMAGINARY PARTS of these FORMULAS, sums involving sines and cosines can be obtained.

Exponential Sum Function

The exponential sum function $e_n(x)$, sometimes also denoted $\exp_n(x)$, is defined by

$$e_n(x) \equiv \sum_{k=0}^{n} \frac{x^k}{k!}$$

$$= \frac{e^x \Gamma(n+1, x)}{\Gamma(n+1)},$$

where $\Gamma(a, x)$ is the upper INCOMPLETE GAMMA FUNCTION and $\Gamma(x)$ is the (complete) GAMMA FUNCTION.

See also GAMMA FUNCTION, INCOMPLETE GAMMA FUNCTION

Exponential Transform

The exponential transform is the transformation of a sequence $a_1, a_2, \ldots$ into a sequence $b_1, b_2, \ldots$ according to the equation

$$1+\sum_{n=1}^{\infty} \frac{b_n x^n}{n!} = \exp\left(\sum_{n=1}^{\infty} \frac{a_n x^n}{n!}\right).$$

The inverse ("logarithmic"rpar; transform is then given by

$$\sum_{n=1}^{\infty} \frac{a_n x^n}{n!} = \ln\left(1+\sum_{n=1}^{\infty} \frac{b_n x^n}{n!}\right).$$

The exponential transform relates the number a_n of labeled CONNECTED GRAPHS on n nodes satisfying some property with the corresponding total number b_n (not necessarily connected) of labeled GRAPHS on n nodes. In this application, the transform is called RIDDELL'S FORMULA for labeled graphs.

Expression

See also QUANTITY

Exradius

The RADIUS of an EXCIRCLE. Let a TRIANGLE have exradius r_1 (sometimes denoted ρ_1), opposite side of length a_1 and angle α_1, AREA Δ, and SEMIPERIMETER s. Then

$$r_1^2 = \left(\frac{\Delta}{s-a_1}\right)^2 \tag{1}$$

$$= \frac{s(s-a_2)(s-a_3)}{s-a_1} \tag{2}$$

$$= 4R\sin\left(\tfrac{1}{2}\alpha_1\right)\cos\left(\tfrac{1}{2}\alpha_2\right)\cos\left(\tfrac{1}{2}\alpha_3\right) \tag{3}$$

(Johnson 1929, p. 189), where R is the CIRCUMRADIUS. Let r be the INRADIUS, then

$$4R = r_1+r_2+r_3-r \tag{4}$$

$$\frac{1}{r_1}+\frac{1}{r_2}+\frac{1}{r_3} = \frac{1}{r} \tag{5}$$

$$rr_1r_2r_3 = \Delta^2. \tag{6}$$

Some fascinating FORMULAS due to Feuerbach are

$$r(r_2r_3+r_3r_1+r_1r_2)=s\Delta=r_1r_2r_3 \tag{7}$$

$$r(r_1+r_2+r_3)=a_2a_3+a_3a_1+a_1a_2-s^2 \tag{8}$$

$$rr_1+rr_2+rr_3+r_1r_2+r_2r_3+r_3r_1 = a_2a_3+a_3a_1+a_1a_2 \tag{9}$$

$$r_2r_3+r_3r_1+r_1r_2-rr_1-rr_2-rr_3=\tfrac{1}{2}(a_1^2+a_2^2+a_3^2) \tag{10}$$

(Johnson 1929, pp. 190–91).

Extended Real Number (Affine)

This entry contributed by DAVID W. CANTRELL

The set $\mathbb{R}\cup\{+\infty, -\infty\}$ obtained by adjoining two improper elements to the set $\mathbb{R}$ of real numbers is normally called the set of (affinely) extended real numbers. Although the notation for this set is not completely standardized, $\bar{\mathbb{R}}$ is commonly used. The set may also be written in interval notation as $[-\infty, +\infty]$. With an appropriate topology, $\bar{\mathbb{R}}$ is the two-point COMPACTIFICATION (or affine closure) of $\mathbb{R}$. The improper elements, the affine infinities $+\infty$ and $-\infty$, correspond to ideal points of the number line. Note that these improper elements are *not* real numbers, and that this system of extended real numbers is not a FIELD.

Instead of writing $+\infty$, many authors write simply ∞. However, the compound symbol $+\infty$ will be used here to represent the positive improper element of $\bar{\mathbb{R}}$,

allowing the individual symbol ∞ to be used unambiguously to represent the unsigned improper element of $\mathbb{R}^*$, the one-point COMPACTIFICATION (or projective closure) of $\mathbb{R}$.

A very important property of $\bar{\mathbb{R}}$, which $\mathbb{R}$ lacks, is that every subset S of $\bar{\mathbb{R}}$ has an INFIMUM (greatest lower bound) and a SUPREMUM (least upper bound). In particular, $\sup \varnothing = -\infty$ and, if S is unbounded above, then $\sup S = +\infty$. Similarly, $\inf \varnothing = +\infty$ and, if S is unbounded below, then $\inf S = -\infty$.

Order relations can be extended from $\mathbb{R}$ to $\bar{\mathbb{R}}$, and arithmetic operations can be partially extended. For $x \in \bar{\mathbb{R}}$,

$$-\infty < x < +\infty \text{ if } x \neq \pm\infty, \; -\infty < +\infty \tag{1}$$

$$-(+\infty) = -\infty, \; -(-\infty) = +\infty \tag{2}$$

$$x + (+\infty) = +\infty + x = +\infty \text{ if } x \neq -\infty \tag{3}$$

$$x + (-\infty) = -\infty + x = -\infty \text{ if } x \neq +\infty \tag{4}$$

$$x \cdot (\pm\infty) = \pm\infty \cdot x = \pm\infty \text{ if } x > 0 \tag{5}$$

$$x \cdot (\pm\infty) = \pm\infty \cdot x = \mp\infty \text{ if } x < 0 \tag{6}$$

$$\frac{x}{\pm\infty} = 0 \text{ if } x \neq \pm\infty \tag{7}$$

$$\left|\frac{x}{0}\right| = +\infty \text{ if } x \neq 0 \tag{8}$$

However, the expressions $+\infty + (-\infty)$, $-\infty + (+\infty)$, and $x/0$ are UNDEFINED.

The above statements which define results of arithmetic operations on $\bar{\mathbb{R}}$ may be considered as abbreviations of statements about determinate LIMIT forms. For example, $-(+\infty) = -\infty$ may be considered as an abbreviation for "If x increases without bound, then $-x$ decreases without bound." Most descriptions of $\bar{\mathbb{R}}$ also make a statement concerning the products of the improper elements and 0, but there is no consensus as to what that statement should be. Some authors (e.g., Kolmogorov 1995, p. 193) state that, like $+\infty + (-\infty)$ and $-\infty + (+\infty)$, $0 \cdot (\pm\infty)$ and $\pm\infty \cdot 0$ should be UNDEFINED, presumably because of the INDETERMINATE status of the corresponding LIMIT forms. Other authors (such as McShane 1983, p. 2) accept $0 \cdot (\pm\infty) = \pm\infty \cdot 0 = 0$, at least as a convention which is useful in certain contexts.

Many results for other operations and functions can be obtained by considering determinate LIMIT forms. For example, a partial extension of the function $f(x, y) = x^y$ can be obtained for $x, y \in \bar{\mathbb{R}}$ as

$$(+\infty)^y = \begin{cases} 0 & \text{if } y < 0 \\ +\infty & \text{if } y > 0 \end{cases} \tag{9}$$

$$x^{+\infty} = \begin{cases} 0 & \text{if } 0 < x < 1 \\ +\infty & \text{if } x > 1 \end{cases} \tag{10}$$

$$x^{-\infty} = \begin{cases} +\infty & \text{if } 0 < x < 1 \\ 0 & \text{if } x > 1. \end{cases} \tag{11}$$

The functions e^x and $\ln|x|$ can be fully extended to $\bar{\mathbb{R}}$, with

$$e^{-\infty} = 0 \tag{12}$$

$$e^{+\infty} = +\infty \tag{13}$$

$$\ln|0| = -\infty \tag{14}$$

$$\ln|\pm\infty| = +\infty. \tag{15}$$

Some other important functions (e.g., $\tanh(\pm\infty) = \pm 1$ and $\tan^{-1}(\pm\infty) = \pm\pi/2$) can be extended to $\bar{\mathbb{R}}$, while others (e.g., $\sin x$, $\cos x$) cannot. Evaluations of expressions involving $+\infty$ and $-\infty$, derived by considering determinate LIMIT forms, are routinely used by computer algebra systems such as *Mathematica* when performing simplifications.

Extended Real Number (Projective)

This entry contributed by DAVID W. CANTRELL

The set $\mathbb{R} \cup \{\infty\}$, obtained by adjoining one improper element to the set $\mathbb{R}$ of real numbers, is the set of projectively extended real numbers. Although notation is not completely standardized, $\mathbb{R}^*$ is used here to denote this set of extended real numbers. With an appropriate topology, $\mathbb{R}^*$ is the one-point COMPACTIFICATION (or projective closure) of $\mathbb{R}$. As shown above, the cross section of the RIEMANN SPHERE consisting of its "real axis" and "north pole" can be used to visualize $\mathbb{R}^*$. The improper element, projective infinity (∞), then corresponds with the ideal point, the "north pole."

In contrast to the signed affine infinities ($+\infty$ and $-\infty$) of the affinely EXTENDED REAL NUMBERS $\bar{\mathbb{R}}$, projective infinity, ∞, is unsigned, like 0. Regrettably, ∞ is also unordered, i.e., for $x \in \mathbb{R}^*$ it can be said neither that $x < \infty$ nor that $x > \infty$. For this reason, $\mathbb{R}^*$ is used much less often in real analysis than is $\bar{\mathbb{R}}$. Thus, if context is not specified, "the extended real numbers" normally refers to $\bar{\mathbb{R}}$, not $\mathbb{R}^*$.

Arithmetic operations can be partially extended from $\mathbb{R}$ to $\mathbb{R}^*$,

$$-(\infty) = \infty,\ x + \infty = \infty + x = \infty \quad \text{if } x \neq \infty,$$

$$x \cdot \infty = \infty \cdot x = \infty \quad \text{if } x \neq 0,$$

$$x/\infty = 0 \quad \text{if } x \neq \infty,$$

and

$$x/0 = \infty \quad \text{if } x \neq 0$$

(by contrast, $x/0$ is UNDEFINED in $\bar{\mathbb{R}}$). The expressions K_n and $0 \cdot \infty$ are most often left UNDEFINED in $\mathbb{R}^*$.

The exponential function e^x cannot be extended to $\mathbb{R}^*$. On the other hand, $\mathbb{R}^*$ is useful when dealing with rational functions and certain other functions. For example, if $\mathbb{R}^*$ is used as the range of $\tan x$, then by taking $\tan((2n+1)\pi/2) = \infty$ for integer n, the domain of the function can be extended to all of $\mathbb{R}$. Extended real numbers are sometimes used in the implementation of FLOATING-POINT ARITHMETIC (Hauser 1996, pp. 158–59).

ExtendedGCD

GREATEST COMMON DIVISOR

Extension (Ideal)

The extension of $\mathfrak{a}$, an IDEAL in COMMUTATIVE RING A, in a RING B, is the IDEAL generated by its image $f(\mathfrak{a})$ under a RING HOMOMORPHISM f. Explicitly, it is any finite sum OF THE FORM $\Sigma\, y_i f(x_i)$ where y_i is in B and x_i is in $\mathfrak{a}$. Sometimes the extension of a is denoted $\mathfrak{a}^e$.

The image $f(\mathfrak{a})$ may not be an ideal if f is not SURJECTIVE. For instance, $f : \mathbb{Z} \to \mathbb{Z}[x]$ is a ring homomorphism and the image of the even integers is not an ideal since it does not contain any non-constant polynomials. The extension of the even integers in this case is the set of polynomials with even coefficients.

The extension of a PRIME IDEAL may not be prime. For example, consider $f : \mathbb{Z} \to \mathbb{Z}[\sqrt{2}]$. Then the extension of the even integers is not a prime ideal since $2 = \sqrt{2} \cdot \sqrt{2}$.

Extension (Set)

The definition of a SET by enumerating its members. An extensional definition can always be reduced to an INTENTIONAL one.

An EXTENSION FIELD is sometimes also called simply an extension.

See also EXTENSION FIELD , INTENSION

References

Russell, B. "Definition of Number." *Introduction to Mathematical Philosophy.* New York: Simon and Schuster, 1971.

Extension Field

A FIELD K is said to be an extension field (or field extension, or extension), denoted K/F, of a field F if F is a SUBFIELD of K. The COMPLEX NUMBERS are an extension field of the REAL NUMBERS, and the REAL NUMBERS are an extension field of the RATIONAL NUMBERS.

The DEGREE) (or relative degree, or index) of an extension field K/F, denoted $[K : F]$, is the dimension of K as a VECTOR SPACE over F, i.e.,

$$[K : F] = \dim_F K.$$

Exterior Algebra

The ALGEBRA of the EXTERIOR PRODUCT, also called an alternating algebra or Grassmann algebra. The study of exterior algebra is also called Ausdehnungslehre and extensions calculus. Exterior algebras are GRADED ALGEBRAS.

In particular, the exterior algebra of a VECTOR SPACE is the DIRECT SUM over k in the natural numbers of the VECTOR SPACES of alternating k-forms on that VECTOR SPACE. The product on this algebra is then the wedge product of forms. The exterior algebra for a VECTOR SPACE V is constructed by forming monomials u, $v \wedge w$, $x \wedge y \wedge z$, etc., where u, v, w, x, y, and z are vectors in V and $\wedge$ is asymmetric multiplication. The sums formed from LINEAR COMBINATIONS of the MONOMIALS are the elements of an exterior algebra.

The exterior algebra of a VECTOR SPACE can also be described as a QUOTIENT VECTOR SPACE,

$$\Lambda^p V = \otimes^p V / W_p, \tag{1}$$

where W_p is the subspace of p-tensors generated by transpositions such as $W_2 = \langle x \otimes y + y \otimes x \rangle$ and $\otimes$ denotes the TENSOR PRODUCT. The EQUIVALENCE CLASS $[x_1 \otimes \ldots \otimes x_p]$ is denoted $x_1 \wedge \ldots \wedge x_p$. For instance,

$$x \wedge y + y \wedge x = 0, \tag{2}$$

since the representatives add to an element of W_2. Consequently, $x \wedge y = -y \wedge x$. Sometimes $\Lambda^p V$ is called the pth exterior power of V, and may also be denoted by $\mathrm{Alt}^p V$.

The alternating products are a SUBSPACE of the tensor products. Define the linear map

$$\mathrm{Alt} : \otimes^p V \to \otimes^p V \tag{3}$$

by

$$\mathrm{Alt}(v_{i_1} \otimes \ldots \otimes v_{i_p}) = \frac{1}{p!} \sum_\sigma \pi(\sigma) v_{i_{\sigma(1)}} \otimes \ldots \otimes v_{i_{\sigma(p)}}, \tag{4}$$

where σ ranges over all PERMUTATIONS of $\{1, \ldots, p\}$, and $\pi(\sigma)$ is the signature of the PERMUTATION, given by the PERMUTATION SYMBOL. Then $\Lambda^p V$ is the image of Alt, as W_p is its NULLSPACE. The constant factor $1/p!$, which is sometimes not used, makes Alt into a PROJECTION OPERATOR.

For example, if V has the BASIS $\{e_1, e_2, e_3, e_4\}$, then

$$\Lambda^0 V = \langle 1 \rangle \tag{5}$$

$$\Lambda^1 V = \langle e_1, e_2, e_3, e_4 \rangle \tag{6}$$

$$\Lambda^2 V = \langle e_1 \wedge e_2, e_1 \wedge e_3, e_1 \wedge e_4, e_2 \wedge e_3, e_2 \wedge e_4, e_3 \wedge e_4 \rangle \tag{7}$$

$$\Lambda^3 V = \langle e_1 \wedge e_2 \wedge e_3, e_1 \wedge e_2 \wedge e_4, e_1 \wedge e_3 \wedge e_3, \times e_2 \wedge e_3 \wedge e_4 \rangle \tag{8}$$

$$\Lambda^4 V = \langle e_1 \wedge e_2 \wedge e_3 \wedge e_4 \rangle, \tag{9}$$

and $\Lambda^k V = \{0\}$ where $k > \dim V$. For a general VECTOR SPACE V of dimension n, the space $\Lambda^p V$ has dimension $\binom{n}{p}$.

Here is a *Mathematica* function that implements the Alt operator, whose image is the alternating subspace of the p-tensors.

```
Alt[x_] := Module[
   {p = TensorRank[x], perms},
   perms = Permutations[Range[p]];
   Sum[
         Signature[perms[[i]]]  Transpose[x,
perms[[i]]],
    {i, p!}
   ]/p!
  ]
```

Here is a *Mathematica* function which tests whether a p-tensor is alternating by testing transpositions.

```
Transpositions[n_] := Module[{i},
  Table[Range[n] /. {i -> i + 1, i + 1 -> i},
{i, n - 1}]
  ] AlternatingQ[a_] := (And[##1] &) @@ ((a
==      -Transpose[a,     #1]     &)     /@
Transpositions[TensorRank[a]])
```

The space $\Lambda^* = \otimes_p \Lambda^p V$ becomes an ALGEBRA with the WEDGE PRODUCT, defined using the function Alt. Also, if $T: V \to W$ is a LINEAR TRANSFORMATION, then the map $T^*,_p: \Lambda^p V \to \Lambda^p W$ sends $v_1 \wedge \ldots \wedge v_p$ to $T(v_1) \wedge \ldots \wedge T(v_p)$. If $n = \dim V$ and $T(v) = Av$ where A is a SQUARE MATRIX, then $T^*,_n (e_1 \wedge \ldots \wedge e_n) = (\det A) e_1 \wedge \ldots \wedge e_n$.

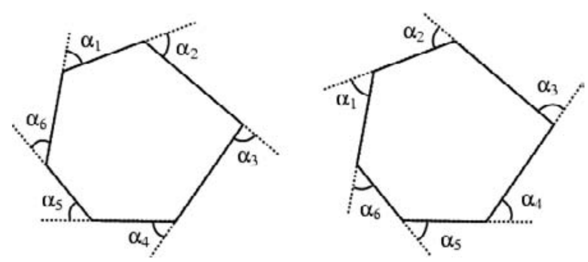
The alternating algebra, also called the exterior algebra, $\Lambda^* V$ is a 2^n dimensional ALGEBRA. In *Mathematica*, an element of the alternating algebra can be represented by an n-nested binary list. For example, {{{1, 2}, {0, 0}}, {{3, 0}, {4, 5}}} represents $e_1 \wedge e_2 \wedge e_3 + 2e_1 \wedge e_3 + 3e_2 \wedge e_3 + 4e_3 + 5$. The WEDGE PRODUCT can defined by the following *Mathematica* function

```
sgntmp[a_, b_] := (-1)^(Mod[Sum[b[[i]], {i,
Length[b]}], 2]) a  sgn[a_] := Module[{d =
TensorRank[a]},
   MapIndexed[sgntmp, a, {d}]
  ] wedge[{a_, b_}, {c_, d_}] := Module[{rnk
= TensorRank[a]},
   If[rnk == 0,
    {a d + b c, b d},
    {wedge[a, d] + wedge[ sgn[b], c], wedge[b,
d]}
   ]
  ]
```

The following *Mathematica* function gives the p powers of an element a in the exterior algebra as a tensor.

```
ExtToTensor[a_, p_] := Module[{d =
TensorRank[a], tmp, ind, indices},
   tmp = Table[2, {d}];
   If[p == 0, (a[[##1]] &) @@ tmp,
    Array[
     (Block[{b},
        b = {##1};
                 ind = ReplacePart[tmp, 1,
Transpose[{b}]];
       Signature[b]/p! (a[[##1]] &) @@ ind] &),
      Table[d, {p}]]]
  ]
```

The rank of an alternating form has a couple different definitions. The rank of a form, used in studying integral manifolds of differential ideals, is the dimension of its ENVELOPE. Another definition is its rank as a TENSOR.



The DIFFERENTIAL K-FORMS in modern geometry are an exterior algebra, and play a role in multivariable calculus. In general, it is only necessary for V to have the structure of a MODULE. So exterior algebras come up in REPRESENTATION THEORY. For example, if V is a REPRESENTATION of a group G, then $\mathrm{Sym}_2 V \otimes \Lambda^2 V$ is a decomposition of $V \otimes V$ into two representations.

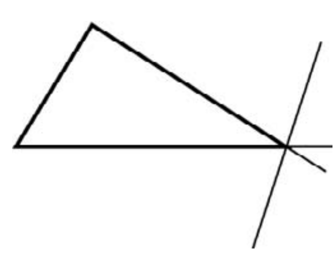
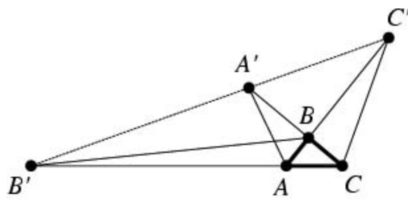
Exterior Angle

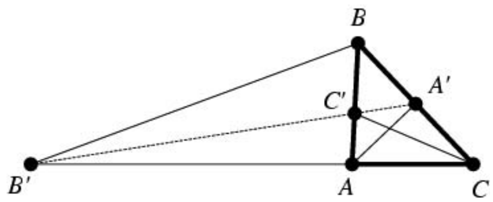


The angle α_i formed between a side of a polygon and the extension of an adjacent side. Since there are two directions in which a side can be extended, there are two exterior angles at each vertex. However, since corresponding angles are opposite, they are also equal. The sum of exterior angles in a convex polygon is equal to 2π RADIANS (360°), since this corresponds to one complete rotation of the polygon.

See also ANGLE, EXTERIOR ANGLE BISECTOR

Exterior Angle Bisector





The exterior bisector of an ANGLE is the LINE or LINE SEGMENT which cuts it into two equal ANGLES on the opposite "side" as the ANGLE.

For a TRIANGLE, the exterior angle bisector bisects the SUPPLEMENTARY ANGLE at a given VERTEX. It also

divides the opposite side externally in the ratio of adjacent sides.

The points A', B', and C' determined on opposite sides of a triangle ΔABC by an ANGLE BISECTOR from each vertex, lie on a straight line if either (1) all or (2) one out of the three bisectors is an external angle bisector (Honsberger 1995).

Exterior Derivative

The exterior derivative of a function f is the ONE-FORM

$$df = \sum_i \frac{\partial f}{\partial x_i}\, dx_i \tag{1}$$

written in a COORDINATE CHART $(x_1, \ldots, x_n)$. Thinking of a function as a zero-form, the exterior derivative extends linearly to all DIFFERENTIAL K-FORMS using the formula

$$d(\alpha \wedge \beta) = d\alpha \wedge \beta + (-1)^p \alpha \wedge d\beta,$$

when α is a k-form and where $\wedge$ is the WEDGE PRODUCT.

The exterior derivative of a k-form is a $(k+1)$-form. For example, for a DIFFERENTIAL K-FORM

$$\omega^1 = b_1\, dx_1 + b_2\, dx_2, \tag{2}$$

the exterior derivative is

$$d\omega^1 = db_1 \wedge dx_1 + db_2 \wedge dx_2. \tag{3}$$

Similarly, consider

$$\omega^1 = b_1(x_1,\ x_2)\, dx_1 + b_2(x_1,\ x_2)\, dx_2. \tag{4}$$

Then

$$\begin{aligned} d\omega^1 &= db_1 \wedge dx_1 + db_2 \wedge dx_2 \\ &= \left(\frac{\partial b_1}{\partial x_1}\, dx_1 + \frac{\partial b_1}{\partial x_2}\, dx_2\right) \wedge\ dx_1 \\ &\quad + \left(\frac{\partial b_2}{\partial x_1}\, dx_1 + \frac{\partial b_2}{\partial x_2}\, dx_2\right) \wedge\ dx_2. \end{aligned} \tag{5}$$

Denote the exterior derivative by

$$Dt \equiv \frac{\partial}{\partial x} \wedge t. \tag{6}$$

Then for a 0-form t,

$$(Dt)_\mu \equiv \frac{\partial t}{\partial x^\mu}, \tag{7}$$

for a 1-form t,

$$(Dt)_{\mu\nu} \equiv \frac{1}{2}\left(\frac{\partial t_\nu}{\partial x^\mu} - \frac{\partial t_\mu}{\partial x^\nu}\right), \tag{8}$$

and for a 2-form t,

$$(Dt)_{ijk} \equiv \tfrac{1}{3}\, \epsilon_{ijk}\left(\frac{\partial t_{23}}{\partial x^1} + \frac{\partial t_{31}}{\partial x^2} + \frac{\partial t_{12}}{\partial x^3}\right), \tag{9}$$

where ϵ_{ijk} is the PERMUTATION TENSOR.

It is always the case that $d(d\alpha) = 0$. When $d\alpha = 0$, then α is called a CLOSED FORM. A TOP-DIMENSIONAL FORM is always a CLOSED FORM. When $\alpha = d\eta$ then α is called an EXACT FORM, so any EXACT FORM is also CLOSED. An example of a CLOSED FORM which is not EXACT is $d\theta$ on the circle. Since θ is a function defined up to a constant multiple of 2π, $d\theta$ is a WELL DEFINED ONE-FORM, but there is no function for which it is the EXTERIOR DERIVATIVE.

The exterior derivative is linear and commutes with the PULLBACK ω^* of DIFFERENTIAL K-FORMS ω. That is,

$$df^*(\alpha) = f^*(d\alpha). \tag{10}$$

Hence the PULLBACK of a CLOSED FORM is closed and the PULLBACK of an EXACT FORM is exact. Moreover, a DE RHAM COHOMOLOGY class $[\alpha]$ has a WELL DEFINED PULLBACK MAP $[f^*(\alpha)]$.

In *Mathematica*, a k-form can be written as an ANTISYMMETRIC k-tensor. Using this format, the following *Mathematica* function computes the exterior derivative of the form a in the (ordered) variables vars.

```
Alt[x_List] := Module[
  {
   p = TensorRank[x],    perms
  },
  perms = Permutations[Range[p]];
      Sum[Signature[perms[[i]]]  Transpose[x,
perms[[i]]],{i, p!}]/p!
 ]  ExtD1[a_List, vars_?List] :=
  Alt[Outer[D[#2, #1] &, vars , a]]
```

It is also possible to use an n-nested binary tree to represent the algebra of differential forms. Using this format, the following *Mathematica* function computes the exterior derivative recursively.

```
ExtD2[{a_List, b_List}, vars_List] :=
   {D[b, First[vars]] - ExtD2[a, Rest[vars]],
ExtD2[b, Rest[vars]]}  ExtD2[{a_?(! ListQ[#1]
&), b_?(! ListQ[#1] &)}, var_?ListQ] :=
   {D[b, First[var]], 0}
```

Exterior Power

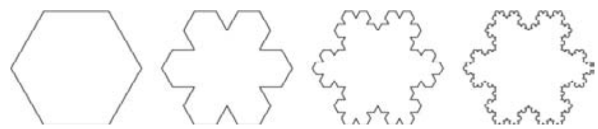
The kth exterior power of an element α in an EXTERIOR ALGEBRA ΛV is given by the WEDGE PRODUCT of α with itself k times. Note that if α has odd degree, then any higher power of α must be zero. The situation for even degree forms is different. For example, if

$$\alpha = e_1 \wedge e_2 + e_3 \wedge e_4 + e_5 \wedge e_6, \quad (1)$$

then

$$\alpha^2 = 2e_1 \wedge e_2 \wedge e_3 \wedge e_4 + 2e_1 \wedge e_2 \wedge e_5 \wedge e_6 + 2e_3 \wedge e_4 \wedge e_5 \wedge e_6 \quad (2)$$

$$\alpha^3 = 6e_1 \wedge e_2 \wedge e_3 \wedge e_4 \wedge e_5 \wedge e_6, \quad (3)$$



$$\alpha^4 = 0. \quad (4)$$

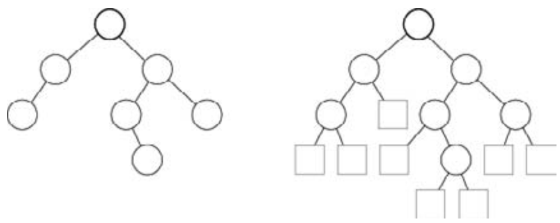
External Contact

TANGENT EXTERNALLY

External Direct Product

The term external direct product is used to refer to either the EXTERNAL DIRECT SUM of groups under the group operation of multiplication, or over infinitely many spaces in which the sum is not required to be finite. In the latter case, the operation is also called the CARTESIAN PRODUCT.



See also CARTESIAN PRODUCT, EXTERNAL DIRECT SUM

External Direct Sum

The CARTESIAN PRODUCT of a finite or infinite set of modules over a ring with only finitely many nonzero entries in each sequence.

See also Cartesian Product, External Direct Product

External Path Length

The sum over all external (square) nodes of the paths from the root of an extended binary tree to each node. For example, in the tree above, the external path length is 25 (Knuth 1997, p. 399–00). The internal and external path lengths are related by

$$E = I + 2n,$$

where n is the number of internal nodes.

See also Extended Binary Tree, Internal Path Length

References

Knuth, D. E. *The Art of Computer Programming, Vol. 1: Fundamental Algorithms, 3rd ed.* Reading, MA: Addison-Wesley, 1997.

External Tensor Product

Suppose that V is a representation of G, and W is a representation of H. Then the tensor product $V \otimes W$ is a representation of the group direct product $G \times H$. An element (g, h) of $G \times H$ acts on a basis element $v \otimes w$ by

$$(g,\ h)(v \otimes w) = gv \otimes hw.$$

To distinguish from the tensor product of representations, the external tensor product is denoted $V \otimes W$, although the only possible confusion would occur when $G = H$.

When V and W are irreducible representations of G and H respectively, then so is the external tensor product. In fact, all irreducible representations of $G \times H$ arise as external direct products of irreducible representations.

Externally Tangent

Tangent Externally

Extra Strong Lucas Pseudoprime

Given the Lucas sequence $U_n(b, -1)$ and $V_n(b, -1)$, define $\Delta = b^2 - 4$. Then an extra strong Lucas pseudoprime to the base b is a composite number $n = 2^r s + (\Delta/n)$, where s is odd and $(n, 2\Delta) = 1$ such that either $U_s \equiv 0 \pmod{n}$ and $V_s \equiv \pm 2 \pmod{n}$, or $V_{2^t s} \equiv 0 \pmod{n}$ for some t with $0 \le t < r - 1$. An extra strong Lucas pseudoprime is a strong Lucas pseudoprime with parameters $(b, -1)$. Composite n are extra strong pseudoprimes for at most 1/8 of possible bases (Grantham 1997).

Extrapolation

Richardson Extrapolation

Extremal Coloring

Extremal Graph

Extremal Graph

In general, an extremal graph is the largest graph of order n which does not contain a given graph G as a subgraph (Skiena 1990, p. 143). Turán studied extremal graphs that do not contain a complete graph K_p as a subgraph.

One much-studied type of extremal graph is a two-coloring of a complete graph K_n of n nodes which contains exactly the number $N \equiv (R + B)_{\min}$ of monochromatic forced triangles and no more (i.e., a minimum of $R + B$ where R and B are the numbers of red and blue triangles). Goodman (1959) showed that for an extremal graph of this type,

$$N(n) = \begin{cases} \frac{1}{3}\, m(m-1)(m-2) & \text{for } n = 2m \\ \frac{1}{3}\, 2m(m-1)(4m+1) & \text{for } n = 4m+1 \\ \frac{1}{3}\, 2m(m+1)(4m-1) & \text{for } n = 4m+3. \end{cases}$$

This is sometimes known as Goodman's formula. Schwenk (1972) rewrote it in the form

$$N(n) = \binom{n}{3} - \left\lfloor \tfrac{1}{2}\, n \left\lfloor \tfrac{1}{4}(n-1)^2 \right\rfloor \right\rfloor,$$

sometimes known as Schwenk's formula, where $\lfloor x \rfloor$ is the floor function. The first few values of $N(n)$

for $n = 1, 2, \ldots$ are 0, 0, 0, 0, 0, 2, 4, 8, 12, 20, 28, 40, 52, 70, 88, ... (Sloane's A014557).

Extremals

A field of extremals is a plane region which is SIMPLY CONNECTED by a one-parameter family of extremals. The concept was invented by Weierstrass.

Extreme and Mean Ratio

GOLDEN MEAN

Extreme Value Distribution

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let M_n denote the "extreme" (i.e., largest) ORDER STATISTIC $X^{\langle n \rangle}$ for a distribution of n elements X_i taken from a continuous UNIFORM DISTRIBUTION. Then the distribution of the M_n is

$$P(M_n < x) = \begin{cases} 0 & \text{if } x < 0 \\ x^n & \text{if } 0 \leq x \leq 1 \\ 1 & \text{if } x > \end{cases} \quad (1)$$

and the MEAN and VARIANCE are

$$\mu = \frac{n}{n+1} \quad (2)$$

$$\sigma^2 = \frac{n}{(n+1)^2(n+2)}. \quad (3)$$

If X_i are taken from a STANDARD NORMAL DISTRIBUTION, then its cumulative distribution is

$$F(x) = \frac{1}{\sqrt{2x}} \int_{-\infty}^{x} e^{-t^2/2}\, dt = \tfrac{1}{2} + \Phi(x), \quad (4)$$

where $\Phi(x)$ is the NORMAL DISTRIBUTION FUNCTION. The probability distribution of M_n is then

$$P(M_n < x) = [F(x)]^n = \frac{n}{\sqrt{2n}} \int_{-\infty}^{x} [F(t)]^{n-1} e^{-t^2/2}\, dt. \quad (5)$$

The MEAN $\mu(n)$ and VARIANCE $\sigma^2(n)$ are expressible in closed form for small n,

$$\mu(1) = 0 \quad (6)$$

$$\mu(2) = \frac{1}{\sqrt{\pi}} \quad (7)$$

$$\mu(3) = \frac{3}{2\sqrt{\pi}} \quad (8)$$

$$\mu(4) = \frac{3}{2\sqrt{\pi}} \left[1 + \frac{2}{\pi} \sin^{-1}\left(\tfrac{1}{3}\right)\right] \quad (9)$$

$$\mu(5) = \frac{5}{4\sqrt{\pi}} \left[1 + \frac{6}{\pi} \sin^{-1}\left(\tfrac{1}{3}\right)\right] \quad (10)$$

and

$$\sigma^2(1) = 1 \quad (11)$$

$$\sigma^2(2) = 1 - \frac{1}{\pi} \quad (12)$$

$$\sigma^2(3) = \frac{4\pi - 9 + 2\sqrt{3}}{4\pi} \quad (13)$$

$$\sigma^2(4) = 1 + \frac{\sqrt{3}}{\pi} - [\mu(4)]^2 \quad (14)$$

$$\sigma^2(5) = 1 + \frac{5\sqrt{3}}{4\pi} + \frac{5\sqrt{3}}{2\pi^2} \sin^{-1}\left(\tfrac{1}{4}\right) - [\mu(5)]^2. \quad (15)$$

No exact expression is known for $\mu(6)$ or $\sigma^2(6)$, but there is an equation connecting them

$$[\mu(6)]^2 + \sigma^2(6) = 1 + \frac{5\sqrt{3}}{4\pi} + \frac{15\sqrt{3}}{2\pi^2} \sin^{-1}\left(\tfrac{1}{4}\right). \quad (16)$$

An analog to the CENTRAL LIMIT THEOREM states that the asymptotic normalized distribution of M_n satisfies one of the three distributions

$$P(y) = \exp(-e^{-y}) \quad (17)$$

$$P(y) = \begin{cases} 0 & \text{if } y \leq 0 \\ \exp[-(-y^{-a})] & \text{if } y > 0 \end{cases} \quad (18)$$

$$P(y) = \begin{cases} \exp[-(-y)^a] & \text{if } y \leq 0 \\ 1 & \text{if } y > 0, \end{cases} \quad (19)$$

also known as GUMBEL, Fréchet, and WEIBULL DISTRIBUTIONS, respectively.

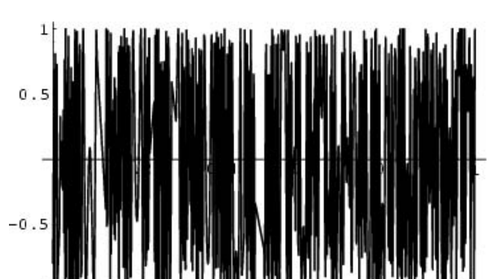
Extreme Value Theorem



If a function $f(x)$ is continuous on a closed interval $[a, b]$, then $f(x)$ has both a MAXIMUM and a MINIMUM on $[a, b]$. If $f(x)$ has an extreme value on an open interval (a, b), then the extreme value occurs at a CRITICAL POINT. This theorem is sometimes also called the WEIERSTRASS EXTREME VALUE THEOREM.

Extremum

A MAXIMUM or MINIMUM. An extremum may be LOCAL (a.k.a. a RELATIVE EXTREMUM; an extremum in a given region which is not the overall MAXIMUM or MINIMUM) or GLOBAL. Functions with many extrema can be very difficult to GRAPH. Notorious examples include the functions $\cos(1/x)$ and $\sin(1/x)$ near $x = 0$

and $\sin(e^{2x+9})$ near 0 and 1.

The latter has

$$\left\lfloor \frac{e^{11}}{\pi} - \frac{1}{2} \right\rfloor - \left\lfloor \frac{e^9}{\pi} - \frac{1}{2} \right\rfloor + 1 = 19085 - 2579 + 1 = 16480$$

extrema in the CLOSED INTERVAL [0,1] (Mulcahy 1996).

See also GLOBAL EXTREMUM, GLOBAL MAXIMUM, GLOBAL MINIMUM, KUHN-TUCKER THEOREM, LAGRANGE MULTIPLIER, LOCAL EXTREMUM, LOCAL MAXIMUM, LOCAL MINIMUM, MAXIMUM, MINIMUM

Extremum Test

Consider a function $f(x)$ in 1-D. If $f(x)$ has a relative extremum at (x_0), then either $f'(x_0) = 0$ or f is not DIFFERENTIABLE at (x_0). Either the first or second DERIVATIVE tests may be used to locate relative extrema of the first kind.

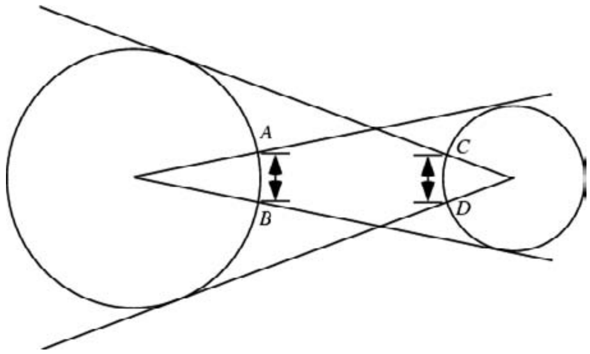
A NECESSARY condition for $f(x)$ to have a MINIMUM (MAXIMUM) at (x_0) is

$$f'(x_0) = 0,$$

and

$$f''(x_0) \geq 0 \quad (f''(x_0) \leq 0).$$

A SUFFICIENT condition is $f'(x_0) = 0$ and $f''(x_0) > 0$ $(f''(x_0) < 0)$. Let $f'(x_0) = 0$, $f''(x_0) = 0$, ..., $f^{(n)}(x_0) = 0$, but $f^{(n+1)}(x_0) \neq 0$. Then $f(x)$ has a RELATIVE MAXIMUM at (x_0) if n is ODD and $f^{(n+1)}(x_0) > 0$, and $f(x)$ has a RELATIVE MINIMUM at (x_0) if n is ODD and $f^{(n+1)}(x_0) > 0$. There is a SADDLE POINT at (x_0) if n is EVEN.



See also EXTREMUM, FIRST DERIVATIVE TEST, RELATIVE MAXIMUM, RELATIVE MINIMUM, SADDLE POINT (FUNCTION), SECOND DERIVATIVE TEST

Extrinsic Curvature

A curvature of a SUBMANIFOLD of a MANIFOLD which depends on its particular EMBEDDING. Examples of extrinsic curvature include the CURVATURE and TORSION of curves in 3-space, or the mean curvature of surfaces in 3-space.

See also CURVATURE, INTRINSIC CURVATURE, MEAN CURVATURE

Eyeball Theorem

Given two circles, draw the tangents from the center of each circle to the sides of the other. Then the line segments *AB* and *CD* are of equal length.

Faber Polynomial

Let

$$f(x) = z + a_1 + a_2 z^{-1} + a_3 z^{-2} + \ldots = z \sum_{n=0}^{\infty} a_n z^{-n}$$
$$\equiv zg(1/z) \quad (1)$$

be a LAURENT POLYNOMIAL with $a_0 = 1$. Then the Faber polynomial $P_m(f)$ in $f(z)$ of degree m is defined such that

$$P_m(f) = z^m + c_{m1} z^{-1} + c_{m2} z^{-2} + \ldots = z^m + G_m(1/z), \quad (2)$$

where

$$G_m(x) = \sum_{n=1}^{\infty} c_{mn} x^n \quad (3)$$

(Schur 1945). Writing

$$[g(x)]^m = \sum_{k=0}^{\infty} a_{mk} x^l \quad (4)$$

for $m = 1, 2, \ldots$ gives the relationship

$$a_{m,m+n} = c_{mn} + a_{m1} c_{m-1,n} + a_{m2} c_{m-2,n}$$
$$+ \ldots + a_{m,m-1} c_{1n}. \quad (5)$$

connecting a_{mn} and c_{mn}.

This polynomial can be used to calculate the number of LATTICE PATHS from a point $(r, 0)$ to a point (a, b) that remain below the line $y = cx$.

Fabry Imbedding

A representation of a PLANAR GRAPH as a planar straight line graph such that no two EDGES cross.

See also PLANAR GRAPH

Face

The intersection of an n-D POLYTOPE with a tangent HYPERPLANE. 0-D faces are known as VERTICES

(nodes), 1-D faces as EDGES, $(n-2)$-D faces as RIDGES, and $(n-1)$-D faces as FACETS.

See also EDGE (POLYHEDRON), FACET, POLYTOPE, RIDGE, VERTEX (POLYHEDRON)

Face-Regular Polyhedron

JOHNSON SOLID

Facet

An $(n-1)$-D FACE of an n-D POLYTOPE. A procedure for generating facets is known as FACETING.

Faceting

Using a set of corners of a SOLID that lie in a plane to form the VERTICES of a new POLYGON is called faceting. Such POLYGONS may outline new FACES that join to enclose a new SOLID, even if the sides of the POLYGONS do not fall along EDGES of the original SOLID.

Factor

A factor is a portion of a quantity, usually an INTEGER or POLYNOMIAL that, when MULTIPLIED by all other factors, give the entire quantity. The determination of factors is called FACTORIZATION (or sometimes "FACTORING"). It is usually desired to break factors down into the smallest possible pieces so that no factor is itself factorable. For INTEGERS, the determination of factors is called PRIME FACTORIZATION. For large quantities, the determination of all factors is usually very difficult except in exceptional circumstances.

See also DIVISOR, FACTORIZATION, GREATEST PRIME FACTOR, LEAST PRIME FACTOR, MULTIPLICATION, POLYNOMIAL FACTORIZATION, PRIME FACTORIZATION, PRIME FACTORIZATION ALGORITHMS

Factor (Graph)

A 1-factor of a GRAPH G with n VERTICES is a set of $n/2$ separate EDGES which collectively contain all n of the VERTICES of G among their endpoints.

See also GRAPH

Factor Base

The primes with LEGENDRE SYMBOL $(n/p)=1$ (less than $N=\pi(d)$ for trial divisor d) which need be considered when using the QUADRATIC SIEVE factorization method.

Factorial

The factorial $n!$ is defined for a POSITIVE INTEGER n as

$$n! \equiv \begin{cases} n\cdot(n-1)\cdots 2\cdot 1 & n=1,2,\ldots \\ 1 & n=0. \end{cases} \tag{1}$$

The factorial $n!$ gives the number of ways in which n objects can be permuted. For example, $3!=6$, since the six possible permutations of $\{1,2,3\}$ are $\{1,2,3\}$, $\{1,3,2\}$, $\{2,1,3\}$, $\{2,3,1\}$, $\{3,1,2\}$, $\{3,2,1\}$. Since there is a single permutation of zero elements (the EMPTY SET $\varnothing$), $0!=1$. The first few factorials for $\lfloor n=0$, 1, 2, ... are 1, 1, 2, 6, 24, 120, ... (Sloane's A000142). An older NOTATION for the factorial is n (Mellin 1909; Lewin 1958, p. 19; Dudeney 1970; Gardner 1978; Conway and Guy 1996).

As n grows large, factorials begin acquiring tails of trailing ZEROS. To calculate the number Z of trailing ZEROS for $n!$, use

$$Z=\sum_{k=1}^{k_{\max}}\left\lfloor\frac{n}{5^k}\right\rfloor, \tag{2}$$

where

$$k_{\max}\equiv\left\lfloor\frac{\ln n}{\ln 5}\right\rfloor \tag{3}$$

and $\lfloor x\rfloor$ is the FLOOR FUNCTION (Gardner 1978, p. 63; Ogilvy and Anderson 1988, pp. 112–14). For $n=1$, 2, ..., the number of trailing zeros are 0, 0, 0, 0, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 3, 3, ... (Sloane's A027868). This is a special application of the general result that the POWER of a PRIME p dividing $n!$ is

$$\epsilon_p(n) = \sum_{k \geq 0} \left\lfloor \frac{n}{p^k} \right\rfloor \tag{4}$$

(Landau 1974, pp. 75–6; Hardy and Wright 1979, pp. 342; Ingham 1990, p. 20; Graham *et al.* 1994; Vardi 1991; Hardy 1999, pp. 18 and 21). Stated another way, the exact POWER of a PRIME p which divides $n!$ is

$$\frac{n - \text{sum of digits of the base} - p \text{ representation of } n}{p-1} \tag{5}$$

Let $a(n)$ be the *last* nonzero digit in $n!$, then the first few values are 2, 6, 4, 2, 2, 4, 2, 8, 8, 8, 6, 8, ... (Sloane's A008904). This sequence was studied by Kakutani (1967), who showed that this sequence is "5-automatic," meaning roughly that there exists a finite automaton which, when given the digits of n in base-5, will wind up in a state for which an output mapping specifies $a(n)$. The exact distribution of digits follows from this result.

By noting that

$$n! \equiv \Gamma(n+1), \tag{6}$$

where $\Gamma(n)$ is the GAMMA FUNCTION for INTEGERS n, the definition can be generalized to COMPLEX values

$$z! \equiv \Gamma(z+1) \equiv \int_0^\infty e^{-t} t^z \, dt. \tag{7}$$

This defines $z!$ for all COMPLEX values of z, except when z is a NEGATIVE INTEGER, in which case $z! = \infty$. Using the identities for GAMMA FUNCTIONS, the values of $(\frac{1}{2}n)!$ (half integral values) can be written explicitly

$$\left(-\frac{1}{2}\right)! = \sqrt{\pi} \tag{8}$$

$$\left(\frac{1}{2}\right)! = \frac{1}{2}\sqrt{\pi} \tag{9}$$

$$\left(n - \frac{1}{2}\right)! = \frac{\sqrt{\pi}}{2^n}(2n-1)!! \tag{10}$$

$$\left(n + \frac{1}{2}\right)! = \frac{\sqrt{\pi}}{2^{n+1}}(2n-1)!!, \tag{11}$$

where $n!!$ is a DOUBLE FACTORIAL.

For INTEGERS s and n with $s < n$,

$$\frac{(s-n)!}{(2s-2n)!} = \frac{(-1)^{n-s}(2n-2s)!}{(n-s)!}. \tag{12}$$

The LOGARITHM of $z!$ is frequently encountered

$$\ln(z!) = \frac{1}{2}\ln\left[\frac{\pi z}{\sin(\pi z)}\right] - \gamma - \sum_{n=1}^\infty \frac{\zeta(2n+1)}{2n+1} z^{2n+1} \tag{13}$$

$$= \frac{1}{2}\ln\left[\frac{\pi z}{\sin(\pi z)}\right] - \frac{1}{2}\ln\left(\frac{1+z}{1-z}\right) + (1-\gamma)z - \sum_{n=1}^\infty [\zeta(2n+1) - 1]\frac{z^{2n+1}}{2n+1} \tag{14}$$

$$= \ln\left[\lim_{n\to\infty} \frac{n!}{(z+1)(z+2)\cdots(z+n)} n^z\right] \tag{15}$$

$$= \lim_{n\to\infty} [\ln(n!) + z\ln n - \ln(z+1) - \ln(z+2) - \ldots - \ln(z+n)] \tag{16}$$

$$= \sum_{n=1}^\infty \frac{z^n}{n!} F_{n-1}(0) \tag{17}$$

$$= -\gamma z + \sum_{n=2}^\infty (-1)^n \frac{z^n}{n}\zeta(n) \tag{18}$$

$$= -\ln(1+z) + z(1-\gamma) + \sum_{n=2}^\infty (-1)^n [\zeta(n) - 1]\frac{z^n}{n}, \tag{19}$$

where γ is the EULER-MASCHERONI CONSTANT, $\zeta(z)$ is the RIEMANN ZETA FUNCTION, and $F_n(z)$ is the POLYGAMMA FUNCTION. The factorial can be expanded in a series

$$z! = \sqrt{2\pi} z^{z+1/2} e^{-z}\left(1 + \frac{1}{2}z^{-1} + \frac{1}{288}z^{-2} - \frac{139}{51840}z^{-3} + \ldots\right) \tag{20}$$

(Sloane's A001163 and A001164). STIRLING'S SERIES gives the series expansion for $\ln(z!)$,

$$\ln(z!) = \frac{1}{2}\ln(2\pi) + \left(z + \frac{1}{2}\right)\ln z - z + \frac{B_2}{2z} + \ldots + \frac{B_{2n}}{2n(2n-1)z^{2n-1}} + \ldots$$

$$= \frac{1}{2}\ln(2\pi) + \left(z + \frac{1}{2}\right)\ln z - z + \frac{1}{12}z^{-1} - \frac{1}{360}z^{-3} + \frac{1}{1260}z^{-5} - \ldots \tag{21}$$

(Sloane's A046968 and A046969), where B_n is a BERNOULLI NUMBER.

Let h be the exponent of the greatest POWER of a PRIME p dividing $n!$. Then

$$h = \sum_{\substack{i=1 \\ p^i \le n}} \left\lfloor \frac{n}{p^i} \right\rfloor. \tag{22}$$

Let g be the number of 1s in the BINARY representation of n. Then

$$g + h = n \tag{23}$$

(Honsberger 1976). In general, as discovered by Legendre in 1808, the POWER m of the PRIME p dividing $n!$ is given by

$$m = \sum_{k=0}^{\infty} \left\lfloor \frac{n}{p^k} \right\rfloor = \frac{n - (n_0 + n_1 + \ldots + n_N}{p - 1}, \tag{24}$$

where the INTEGERS n_1, ..., n_N are the digits of n in base p (Ribenboim 1989).

The numbers $n! + 1$ are prime for $n = 1$, 2, 3, 11, 27, 37, 41, 73, 77, 116, 154, ... (Sloane's A002981; Wells 1986, p. 70), and the numbers $n! - 1$ are prime for $n = 3$, 4, 6, 7, 12, 14, 30, 32, 33, 38, 94, 166, ... (Sloane's A002982). In general, the power-product sequences (Mudge 1997) are given by $S_k^{\pm}(n) = (n!)^k \pm 1$. The first few terms of $S_2^+(n)$ are 2, 5, 37, 577, 14401, 518401, ... (Sloane's A020549), and $S_2^+(n)$ is PRIME for $n = 1$, 2, 3, 4, 5, 9, 10, 11, 13, 24, 65, 76, ... (Sloane's A046029). The first few terms of $S_2^-(n)$ are 0, 3, 35, 575, 14399, 518399, ... (Sloane's A046032), but $S_2^-(n)$ is PRIME for only $n = 2$ since $S_2^-(n) = (n!)^2 - 1 = (n! + 1)(n! - 1)$ for $n > 2$. The first few terms of $S_3^-(n)$ are 0, 7, 215, 13823, 1727999, ... (Sloane's A046033), and the first few terms of $S_3^+(n)$ are 2, 9, 217, 13825, 1728001, ... (Sloane's A019514).

The first few numbers n such that the sum of the factorials of their digits is equal to the PRIME COUNTING FUNCTION $\pi(n)$ are 6500, 6501, 6510, 6511, 6521, 12066, 50372, ... (Sloane's A049529). This sequence is finite, with the largest term being $a_{23} = 11,071,599$.

There are three numbers less than 200,000 for which

$$(n-1)! + 1 \equiv 0 (\mathrm{mod}\ n^2), \tag{25}$$

namely 5, 13, and 563 (Le Lionnais 1983). BROWN NUMBERS are pairs (m, n) of INTEGERS satisfying the condition of BROCARD'S PROBLEM, i.e., such that

$$n! + 1 = m^2, \tag{26}$$

Only three such numbers are known: (5, 4), (11, 5), (71, 7). Erdos conjectured that these are the only three such pairs (Guy 1994, p. 193).

Factorial Number

FACTORIAL

Factorial Prime

A PRIME OF THE FORM $n! \pm 1$. $n!+1$ is PRIME for 1, 2, 3, 11, 27, 37, 41, 73, 77, 116, 154, 320, 340, 399, 427, 872, 1477, 6380, ... (Sloane's A002981). No others are known, but N. Kuosa is coordinating a search in the range $23,000 < n < 30,000$.

$n!-1$ is PRIME for 3, 4, 6, 7, 12, 14, 30, 32, 33, 38, 94, 166, 324, 379, 469, 546, 974, 1963, 3507, 3610, 6917, ... (Sloane's A002982).

Factorial Products

The only known factorials which are products of factorials in an ARITHMETIC SEQUENCE are

$$\begin{aligned} 0!1! &= 1! \\ 1!2! &= 2! \\ 0!1!2! &= 2! \\ 6!7! &= 10! \\ 1!3!5! &= 6! \\ 1!3!5!7! &= 10! \end{aligned}$$

(Madachy 1979).

There are no identities OF THE FORM

$$n! = a_1!a_2!\cdots a_r! \quad (1)$$

for $r \geq 2$ with $a_i \geq a_j \geq 2$ for $i < j$ for $n \leq 18160$ except

$$9! = 7!3!3!2! \quad (2)$$

$$10! = 7!6! = 7!5!3! \quad (3)$$

$$16! = 14!5!2! \quad (4)$$

(Guy 1994, p. 80).

Factorial Sums

The sum-of-factorials function is defined by

$$\sum(n) \equiv \sum_{k=1}^{n} k!$$

$$= \frac{-e + \mathrm{ei}(1) + \pi i + \mathrm{E}_{2n+1}(-1)]\Gamma(n+2)}{e}, \quad (1)$$

$$= \frac{-e + \mathrm{ei}(1) + \Re[\mathrm{E}_{2n+1}(-1)]\Gamma(n+2)}{e}, \quad (2)$$

where $\mathrm{ei}(1) \approx 1.89512$ is the EXPONENTIAL INTEGRAL, E_n is the E_N-FUNCTION, $\Re[z]$ is the REAL PART of z, and I is the IMAGINARY NUMBER. The first few values are 1, 3, 9, 33, 153, 873, 5913, 46233, 409113, ... (Sloane's A007489). $\Sigma(n)$ cannot be written as a hypergeometric term plus a constant (Petkovsek *et al.* 1996). However the sum

$$\sum{}'(n) \equiv \sum_{k=1}^{n} kk! = (n+1)! - 1 \quad (3)$$

has a simple form, with the first few values being 1, 5, 23, 119, 719, 5039, ... (Sloane's A033312).

There are only four INTEGERS equal to the sum of the factorials of their digits. Such numbers are called FACTORIONS. While no factorial greater than 1! is a SQUARE NUMBER, D. Hoey listed sums $< 10^{12}$ of distinct factorials which give SQUARE NUMBERS, and J. McCranie gave the one additional sum less than $21! = 5.1 \times 10^{19}$:

$$0! + 1! + 2! = 2^2$$
$$1! + 2! + 3! = 3^2$$
$$1! + 4! = 5^2$$
$$1! + 5! = 11^2$$
$$4! + 5! = 12^2$$
$$1! + 2! + 3! + 6! = 27^2$$
$$1! + 5! + 6! = 29^2$$
$$1! + 7! = 71^2$$
$$4! + 5! + 7! = 72^2$$
$$1! + 2! + 3! + 7! + 8! = 213^2$$
$$1! + 4! + 5! + 6! + 7! + 8! = 215^2$$
$$1! + 2! + 3! + 6! + 9! = 603^2$$
$$1! + 4! + 8! + 9! = 635^2$$
$$1! + 2! + 3! + 6! + 7! + 8! + 10! = 1917^2$$

$$1! + 2! + 3! + 7! + 8! + 9! + 10! + 11! + 12! + 13! + 14! + 15! = 1183893^2$$

(Sloane's A014597).

The first few values of the alternating SUM

$$a(n) \equiv \sum_{i=1}^{n} (-1)^{n-i} i! \quad (4)$$

$$= (-1)^n \left[-1 - e\,\mathrm{ei}(-1) + (-1)^n \mathrm{E}_{n+2}(1)\Gamma(n+2)\right], \quad (5)$$

where $\mathrm{ei}(x)$ is the EXPONENTIAL INTEGRAL, $E_n(x)$ is the *En*-FUNCTION, and $\Gamma(x)$ is the GAMMA FUNCTION, are 1, 1, 5, 19, 101, 619, 4421, 35899, ... (Sloane's A005165), and the first few values n for which $a(n)$ are prime are n = 3, 4, 5, 6, 7, 8, 10, 15, 19, 41, 59, 61, 105, 160, 661, 2653, 3069, 3943, 4053, 4998, ... (Sloane's A001272, Guy 1994, p. 100). Zivkovic (1999) has shown that the number of such primes is finite.

Sums with powers of an index in the NUMERATOR and products of FACTORIALS in the DENOMINATOR can often be done analytically. For example, for numerator 1,

$$\sum_{i=1}^{n} \frac{1}{(k_{1+i})!(k_{2+i})!} = {}_1\tilde{F}_2(1; 2+k_1, 2+k_2; 1)$$
$$- {}_1\tilde{F}_2(1; n+k_1+2, n+k_2+2; 1) \quad (6)$$

$$\sum_{i=1}^{n} \frac{1}{(k_1 - i)!(k_2 + i)!} = \frac{{}_2\tilde{F}(1, 1-k_1; k_2+2; -1)}{\Gamma(k_1)}$$
$$- \frac{{}_2\tilde{F}(1, n-k_1+1; n+k_2+2; -1)}{\Gamma(k_1 - n)} \quad (7)$$

where ${}_p\tilde{F}_q$ is a REGULARIZED HYPERGEOMETRIC FUNCTION. For numerator i,

$$\sum_{i=1}^{n} \frac{i}{(k_1+i)!(k_2+i)!}$$
$$= -(n+1)\,{}_1\tilde{F}_2(1; n+k_1+2, n+k_2+2; 1)$$
$$+ {}_1\tilde{F}_2(2; k_1+2, k_2+2; 1)$$
$$- {}_1\tilde{F}_2(2; n+k_1+3, n+k_2+3; 1) \quad (8)$$

$$\sum_{i=1}^{n} \frac{i}{(k_1-i)!(k_2+i)!}$$
$$- \frac{(n+1)\,{}_2\tilde{F}_1(1, n-k_1+1; n+k_2+2; -1)}{\Gamma(k_1 - n)}$$
$$+ \frac{{}_2\tilde{F}_1(2, 1-k_1; k_2+2; -1)}{\Gamma(k_1)}$$
$$- \frac{{}_2\tilde{F}_1(2, n-k_1+2; n+k_2+3; -1)}{\Gamma(k_1 - n - 1)}. \quad (9)$$

These sums simplify substantially for special values of k_1 and k_2. For example, with $k_1 = k_2 = n$,

$$\sum_{i=1}^{n} \frac{1}{(n-i)!(n+i)!} = \frac{2^{2n-1}}{\Gamma(2n+1)} - \frac{1}{2[\Gamma(n)]^2} \quad (10)$$

$$\sum_{i=1}^{n} \frac{i}{(n-i)!(n+i)!} = \frac{1}{2\Gamma(n)\Gamma(n+1)} \quad (11)$$

$$\sum_{i=1}^{n} \frac{i^2}{(n-i)!(n+i)!}$$
$$= \frac{1}{2\Gamma(n)\Gamma(n+1)} + \frac{2\,{}_2\tilde{F}_1(3, 2-n; n+3; -1)}{\Gamma(n-1)}. \quad (12)$$

With $k_1 = n$ and $k_2 = n-1$,

$$\sum_{i=1}^{n} \frac{1}{(n-i)!(n-1+i)!} = \frac{4^{n-1}}{\Gamma(2n)} \quad (13)$$

$$\sum_{i=1}^{n} \frac{i}{(n-i)!(n-1+i)!} = \frac{1}{2[\Gamma(n)]^2} + \frac{2^{2n-3}}{\Gamma(2n)}. \quad (14)$$

With $k_1 = n$ and $k_2 = n+1$,

$$\sum_{i=1}^{n} \frac{1}{(n-i)!(n+1+i)!}$$
$$= \frac{4^n}{\Gamma(2n+2)} - \frac{1}{\Gamma(n+1)\Gamma(n+2)} \quad (15)$$

$$\sum_{i=1}^{n} \frac{1}{(n-i)!(n+1+i)!} = \frac{\Gamma(n)+\Gamma(n+1)}{2\Gamma(n)\Gamma(n+1)\Gamma(n+2)} - \frac{2^{2n-1}}{\Gamma(2n+2)} \tag{16}$$

Sums of factorial POWERS include

$$\sum_{n=0}^{\infty} \frac{(n!)^2}{(2n)!} = \frac{2}{27}\left(18+\sqrt{3}\pi\right) \tag{17}$$

$$\sum_{n=0}^{\infty} \frac{(n!)^3}{(3n)!} = {}_3F_2\left(1,1,1;\frac{1}{3},\frac{2}{3};\frac{1}{27}\right) \tag{18}$$

$$= \int_0^1 \left[P(t)+Q(t)\cos^{-1}R(t)\right]dt, \tag{19}$$

where

$$P(t) = \frac{2(8+7t^2-7t^3)}{(4-t^2+t^3)^2} \tag{20}$$

$$Q(t) = \frac{4t(1-t)(5+t^2-t^3)}{(4-t^2+t^3)^2\sqrt{(1-t)(4-t^2+t^3)}} \tag{21}$$

$$R(t) = 1-\frac{1}{2}\left(t^2-t^3\right) \tag{22}$$

(Schroeppel and Gosper 1972). In general,

$$\sum_{n=0}^{\infty} \frac{(n!)^k}{(kn)!} = {}_kF_{k-1}\left(\underbrace{1,\ldots,1}_{k};\frac{1}{k},\frac{2}{k},\ldots,\frac{k-1}{k};\frac{1}{k^k}\right). \tag{23}$$

Identities satisfied by sums of factorials include

$$\sum_{k=0}^{\infty} \frac{1}{k!} = e = 2.718281828\ldots \tag{24}$$

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{k!} = e^{-1} = 0.3678794411\ldots \tag{25}$$

$$\sum_{k=0}^{\infty} \frac{1}{(k!)^2} = I_0(2) = 2.279585302\ldots \tag{26}$$

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{(k!)^2} = J_0(2) = 0.2238907791\ldots \tag{27}$$

$$\sum_{k=0}^{\infty} \frac{1}{(2k)!} = \cosh 1 = 1.543080634\ldots \tag{28}$$

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{(2k)!} = \cos 1 = 0.5403023058\ldots \tag{29}$$

$$\sum_{k=0}^{\infty} \frac{1}{(2k+1)!} = \sinh 1 = 1.175201193\ldots \tag{30}$$

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)!} = \sin 1 = 0.8414709848\ldots \tag{31}$$

(Spanier and Oldham 1987), where $I_0(x)$ is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND, $J_0(x)$ is a BESSEL FUNCTION OF THE FIRST KIND, $\cosh x$ is the HYPERBOLIC COSINE, $\cos x$ is the COSINE, $\sinh x$ is the HYPERBOLIC SINE, and $\sin x$ is the SINE.

Factorial2

DOUBLE FACTORIAL

Factoring

FACTORIZATION

Factorion

A factorion is an INTEGER which is equal to the sum of FACTORIALS of its digits. There are exactly four such numbers:

$$1 = 1! \tag{1}$$

$$2 = 2! \tag{2}$$

$$145 = 1!+4!+5! \tag{3}$$

$$40,585 = 4!+0!+5!+8!+5! \tag{4}$$

(Sloane's A014080; Gardner 1978, Madachy 1979, Pickover 1995). Obviously, the factorion of an n-digit number cannot exceed $n \cdot 9!$.

Factorization

The determination of FACTORS (DIVISORS) of a given INTEGER("PRIME FACTORIZATION"), POLYNOMIAL ("POLYNOMIAL FACTORIZATION"), etc. In many cases of interest (particularly PRIME FACTORIZATION, factorization is unique, and so gives the "simplest" representation of a given quantity in terms of smaller parts.

The terms "factorization" and "factoring" are used synonymously.

Fagnano's Theorem

If $P(x,y)$ and $P(x',y')$ are two points on an ELLIPSE

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1, \quad (1)$$

with ECCENTRIC ANGLES ϕ and ϕ' such that

$$\tan\phi\tan\phi'=\frac{b}{a} \quad (2)$$

and $A=P(a,0)$ and $B=P(0,b)$. Then

$$\mathrm{arc}BP+\mathrm{arc}BP'=\frac{e^2xx'}{a}. \quad (3)$$

This follows from the identity

$$E(u,k)+E(v,k)-E(k)=k^2\,\mathrm{sn}(u,k)\,\mathrm{sn}(v,k), \quad (4)$$

where $E(u,k)$ is an incomplete ELLIPTIC INTEGRAL OF THE SECOND KIND, $E(k)$ is a complete ELLIPTIC INTEGRAL OF THE SECOND KIND, and $\mathrm{sn}(v,k)$ is a JACOBI ELLIPTIC FUNCTION. If P and p' coincide, the point where they coincide is called FAGNANO'S POINT.

Faithful Group Action

A GROUP ACTION $\phi : G \times X \to X$ is called faithful if there are no group elements g such that $gx = x$ for all $x \in X$. Equivalently, the map ϕ induces an INJECTION of G into the SYMMETRIC GROUP Sx. So G can be identified with a PERMUTATION SUBGROUP.

Most actions that arise naturally are faithful. An example of an action which is not faithful is the action $e^{i(x+y)}$ of $G = \mathbb{R}^2 = \{(x,y)\}$ on $X = \mathbb{S}^1 = \{e^{i\theta}\}$, i.e., $\phi(x,y,e^{i\theta}) = e^{i(\theta+x+y)}$.

Fallacy

A fallacy is an incorrect result arrived at by apparently correct, though actually specious reasoning. The great Greek geometer Euclid wrote an entire book on geometric fallacies which, unfortunately, has not survived (Gardner 1984, p. ix).

The most common example of a mathematical fallacy is the "proof" that $1 = 2$ as follows. Let $a = b$, then

$$ab = a^2 \quad (1)$$

$$ab - b^2 = a^2 - b^2 \quad (2)$$

$$b(a-b) = (a+b)(a-b) \quad (3)$$

$$b = a + b \quad (4)$$

$$b = 2b \quad (5)$$

$$1 = 2. \quad (6)$$

The incorrect step is (4), in which DIVISION BY ZERO $(a - b = 0)$ is performed, which is not an allowed algebraic operation. Similarly flawed reasoning can be used to show that $0 = 1$, or any number equals any other number.

Ball and Coxeter (1987) give other such examples in the areas of both arithmetic and geometry.

See also DIVISION BY ZERO

Falling Factorial

For $n \geq 0$, the falling factorial is defined by

$$(x)_n = x(x-1)\cdots(x-n+1), \quad (1)$$

and is related to the RISING FACTORIAL $x^{(n)}$ (a.k.a. POCHHAMMER SYMBOL) by

$$(x)_n = (-1)^n(-x)^{(n)}. \quad (2)$$

The falling factorial can be implemented in *Mathematica* as

```
FallingFactorial[x_, n_] := (-1)Pochhammer[-
x, n]
```

The falling factorial is also called a binomial polynomial or lower factorial.

Unfortunately, there are two notations used for the falling and rising factorials, $(x)_n$ and $x^{(n)}$, which are unfortunately polar opposites of one another. In combinatorial usage, the falling factorial is denoted $(x)_n$ and the RISING FACTORIAL is denoted $(x)^{(n)}$ (Comtet 1974, p. 6; Roman 1984, p. 5; Hardy 1999, p. 101), whereas in the calculus of FINITE DIFFERENCES and the theory of special functions, the falling factorial is denoted $x^{(n)}$ and the RISING FACTORIAL is denoted $(x)_n$ (Roman 1984, p. 5; Abramowitz and Stegun 1972, p. 256; Spanier 1987). Extreme caution is therefore needed in interpreting the meanings of the notations $(x)_n$ and $x^{(n)}$. *In this work, the notation $(x)_n$ is used for the falling factorial*, potentially causing confusion with the POCHHAMMER SYMBOL (another name for the RISING FACTORIAL, which is universally denoted $(x)_n$).

The first few falling factorials are

$(x)_0 = 1$

$$(x)_1 = x$$

$$(x)_2 = x(x-1) = x^2 - x$$

$$(x)_3 = x(x-1)(x-2) = x^3 - 3x^2 + 2x$$

$$(x)_4 = x(-1)(x-2)(x-3) = x^4 - 6x^3 + 11x^2 - 6x.$$

A sum formula connecting the falling factorial $(x)_n$ and rising factorial $x^{(n)}$,

$$(x)_n = \sum_{k=0}^{n} c_{nk} x^{(k)}, \tag{3}$$

is given using the Sheffer formalism with

$$g(t) = 1 \tag{4}$$

$$f(t) = e^t - 1 \tag{5}$$

$$h(t) = 1 \tag{6}$$

$$l(t) = 1 - e^{-t}, \tag{7}$$

which gives the GENERATING FUNCTION

$$\sum_{n=0}^{\infty} \frac{t_n(x)}{n!} t^n = \sum_{n=0}^{\infty} \frac{1}{n!} \sum_{k=0}^{n} c_{nk} x^k t^k = e^{tx/(1+t)}, \tag{8}$$

$$= 1 + xt + \frac{1}{2}(x^2 - 2x)t^2 + \frac{1}{6}(x^3 - 6x^2 + 6x)t^3$$

$$+ \frac{1}{24}(x^4 - 12x^3 + 36x^2 - 24x)t^4 + \ldots, \tag{9}$$

where

$$t_n(x) = \sum_{k=0}^{n} c_{nk} x^k. \tag{10}$$

Reading the coefficients off gives

$$c_{00} = 1$$

$$c_{11} = 1 \quad c_{10} = 0$$

$$c_{22} = 1 \quad c_{21} = -2 \quad c_{20} = 0$$

$$c_{33} = 1 \quad c_{32} = -6 \quad c_{31} = 6 \quad c_{30} = 0,$$

so,

$$(x)_0 = x^{(0)} \tag{11}$$

$$(x)_1 = x^{(1)} \tag{12}$$

$$(x)_2 = x^{(2)} - 2x^{(1)} \tag{13}$$

$$(x)_3 = x^{(3)} - 6x^{(2)} + 6x^{(1)}, \tag{14}$$

etc. (and the formula given by Roman 1984, p. 133, is incorrect).

The falling factorial is an associated SHEFFER SEQUENCE with

$$f(t) = e^t - 1 \tag{15}$$

(Roman 1984, p. 29), and has GENERATING FUNCTION

$$\sum_{k=0}^{\infty} \frac{(x)_k}{k!} t^k = e^{x \ln(1+t)} = (1+t)^x, \tag{16}$$

which is equivalent to the BINOMIAL THEOREM

$$\sum_{k=0}^{\infty} \binom{x}{k} t^k = (1+t)^x. \tag{17}$$

The binomial identity of the SHEFFER SEQUENCE is

$$(x+y)_n = \sum_{k=0}^{n} \binom{n}{k} (x)_k (y)_{n-k}, \tag{18}$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT, which can be rewritten as

$$\binom{x+y}{n} = \sum_{k=0}^{\infty} \binom{x}{k} \binom{y}{n-k}, \tag{19}$$

known as the CHU-VANDERMONDE IDENTITY. The falling factorials obey the RECURRENCE RELATION

$$x(x)_n = (x)_{n+1} + n(x)_n \tag{20}$$

(Roman 1984, p. 61).

Faltung (Form)

Let A and B be bilinear forms

$$A = A(x, y) = \sum\sum a_{ij} x_i y_i$$

$$B = B(x, y) = \sum\sum b_{ij} x_i y_i$$

and suppose that A and B are bounded in $[p, p']$ with bounds M and N. Then

$$F = F(A, B) = \sum\sum f_{ij} x_i y_j,$$

where the series

$$f_{ij} = \sum_k a_{ik} b_{kj}$$

is absolutely convergent, is called the faltung of A and B. F is bounded in $[p, p']$, and its bound does not exceed MN.

Fano Configuration

FANO PLANE

Fano Plane

The 2-D finite PROJECTIVE PLANE over $GF(2)$ ("of order two"), illustrated above. It is a BLOCK DESIGN with $v = 7$, $k = 3$, $\lambda = 1$, $r = 3$, and $b = 7$, the STEINER TRIPLE SYSTEM $S(7)$, and the unique 7_3 CONFIGURATION.

The Fano plane also solves the TRANSYLVANIA LOTTERY, which picks three numbers from the INTEGERS 1–4. Using two Fano planes we can guarantee matching two by playing just 14 times as follows. Label the VERTICES of one Fano plane by the INTEGERS 1–, the other plane by the INTEGERS 8–4. The 14 tickets to play are the 14 lines of the two planes. Then if (a, b, c) is the winning ticket, at least two of a, b, c are either in the interval [1, 7] or [8, 14]. These two numbers are on exactly one line of the corresponding plane, so one of our tickets matches them.

The Lehmers (1974) found an application of the Fano plane for factoring INTEGERS via QUADRATIC FORMS. Here, the triples of forms used form the lines of the PROJECTIVE GEOMETRY on seven points, whose planes are Fano configurations corresponding to pairs of residue classes mod 24 (Lehmer and Lehmer 1974, Guy 1975, Shanks 1985). The group of AUTOMORPHISMS (incidence-preserving BIJECTIONS) of the Fano plane is the SIMPLE GROUP of ORDER 168 (Klein 1870).

Farey Fraction

FAREY SEQUENCE

Farey Sequence

The Farey sequence F_n for any POSITIVE INTEGER n is the set of irreducible RATIONAL NUMBERS a/b with $0 \le a \le b \le n$ and $(a, b) = 1$ arranged in increasing order. The first few are

$$F_1 = \left\{ \frac{0}{1}, \frac{1}{1} \right\} \tag{1}$$

$$F_2 = \left\{ \frac{0}{1}, \frac{1}{2}, \frac{1}{1} \right\} \tag{2}$$

$$F_3 = \left\{ \frac{0}{1}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{1}{1} \right\} \tag{3}$$

$$F_4 = \left\{ \frac{0}{1}, \frac{1}{4}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{1}{1} \right\} \tag{4}$$

$$F_5 = \left\{ \frac{0}{1}, \frac{1}{5}, \frac{1}{4}, \frac{1}{3}, \frac{2}{5}, \frac{1}{2}, \frac{3}{5}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \frac{1}{1} \right\} \tag{5}$$

(Sloane's A006842 and A006843). Except for F_1, each F_n has an ODD number of terms and the middle term is always 1/2.

Let p/q, p'/q', and p''/q'' be three successive terms in a Farey series. Then

$$qp' - pq' = 1 \tag{6}$$

$$\frac{p'}{q'} = \frac{p + p''}{q + q''}. \tag{7}$$

These two statements are actually equivalent (Hardy and Wright 1979, p. 24). For a method of computing a successive sequence from an existing one of n terms, insert the MEDIANT fraction $(a + b)/(c + d)$ between terms a/c and b/d when $c + d \le n$ (Hardy and Wright 1979, pp. 25–6; Conway and Guy 1996; Apostol 1997). Given $0 \le a/b < c/d \le 1$ with $bc - ad = 1$, let h/k be the MEDIANT of a/b and c/d. Then $a/b < h/k < c/d$, and these fractions satisfy the unimodular relations

$$bh - ak = 1 \tag{8}$$

$$ck - dh = 1 \tag{9}$$

(Apostol 1997, p. 99).

The number of terms $N(n)$ in the Farey sequence for the INTEGER n is

$$N(n) = 1 + \sum_{k=1}^{n} \phi(k) = 1 + \Phi(n), \tag{10}$$

where $\phi(k)$ is the TOTIENT FUNCTION and $\Phi(n)$ is the SUMMATORY FUNCTION of $\phi(k)$, giving 2, 3, 5, 7, 11, 13, 19, ... (Sloane's A005728). The asymptotic limit for the function $N(n)$ is

$$N(n) \sim \frac{3n^2}{\pi^2} = 0.3039635509 n^2 \tag{11}$$

(Vardi 1991, p. 155).

FORD CIRCLES provide a method of visualizing the Farey sequence. The Farey sequence F_n defines a subtree of the STERN-BROCOT TREE obtained by pruning unwanted branches (Graham *et al.* 1994).

See also FORD CIRCLE, MEDIANT, MINKOWSKI'S QUESTION MARK FUNCTION, RANK (SEQUENCE), STERN-BROCOT TREE

Farey Series

FAREY SEQUENCE

Farkas's Lemma

The system

$$\mathsf{A}x = x, \quad x \geq 0$$

has no solution IFF the system

$$\mathsf{A}^{\mathrm{T}}\mathrm{w} \leq 0, \quad \mathrm{b}^{\mathrm{T}} > 0$$

has a solution (Fang and Puthenpura 1993, p. 60). This LEMMA is used in the proof of the KUHN-TUCKER THEOREM.

Fast Fibonacci Transform

For a general second-order RECURRENCE RELATION

$$f_{n+1} = xf_n + yf_{n-1}, \tag{1}$$

define a multiplication rule on ordered pairs by

$$(A,B)(C,D) = (AD + BC + xAC, BD + yAC). \tag{2}$$

The inverse is then given by

$$(A,B)^{-1} = \frac{(-A, xA + B)}{B^2 + xAB - yA^2}, \tag{3}$$

and we have the identity

$$(f_1, yf_0)(1,0)^n = (f_{n+1}, yf_n) \tag{4}$$

(Beeler *et al.* 1972, Item 12).

Fast Fourier Transform

The fast Fourier transform (FFT) is a DISCRETE FOURIER TRANSFORM ALGORITHM which reduces the number of computations needed for N points from $2N^2$ to $2N \lg N$, where LG is the base-2 LOGARITHM. If the function to be transformed is not harmonically related to the sampling frequency, the response of an FFT looks like a SINC FUNCTION (although the integrated POWER is still correct). ALIASING (LEAKAGE) can be reduced by APODIZATION using a TAPERING FUNCTION. However, ALIASING reduction is at the expense of broadening the spectral response.

FFTs were first discussed by Cooley and Tukey (1965), although Gauss had actually described the critical factorization step as early as 1805 (Gergkand 1969, Strang 1993). A DISCRETE FOURIER TRANSFORM can be computed using an FFT by means of the DANIELSON-LANCZOS LEMMA if the number of points N is a POWER of two. If the number of points N is not a POWER of two, a transform can be performed on sets of points corresponding to the prime factors of N which is slightly degraded in speed. An efficient real Fourier transform algorithm or a fast HARTLEY TRANSFORM (Bracewell 1999) gives a further increase in speed by approximately a factor of two. Base-4 and base-8 fast Fourier transforms use optimized code, and can be 20–0% faster than base-2 fast Fourier transforms. PRIME factorization is slow when the factors are large, but discrete Fourier transforms can be made fast for $N = 2, 3, 4, 5, 7, 8, 11, 13,$ and 16 using the WINOGRAD TRANSFORM ALGORITHM (Press *et al.* 1992, pp. 412–13, Arndt).

Fast Fourier transform algorithms generally fall into two classes: decimation in time, and decimation in frequency. The Cooley-Tukey FFT ALGORITHM first rearranges the input elements in bit-reversed order, then builds the output transform (decimation in time). The basic idea is to break up a transform of length N into two transforms of length $N/2$ using the identity

$$\begin{aligned}\sum_{n=0}^{N-1} a_n e^{-2\pi ink/N} &= \sum_{n=0}^{N/2-1} a_{2n} e^{-2\pi i(2n)k/N} + \sum_{n=0}^{N/2-1} a_{2n+1} e^{-2\pi i(2n+1)k/N} \\ &= \sum_{n=0}^{N/2-1} a_n^{\text{even}} e^{-2\pi ink/(N/2)} + e^{-2\pi ik/N} \\ &\quad \times \sum_{n=0}^{N/2-1} a_n^{\text{odd}} e^{-2\pi ink/(N/2)},\end{aligned}$$

sometimes called the DANIELSON-LANCZOS LEMMA.

The easiest way to visualize this procedure is perhaps via the FOURIER MATRIX.

The Sande-Tukey ALGORITHM (Stoer and Bulirsch 1980) first transforms, then rearranges the output values (decimation in frequency).

Fatou's Theorems

Let $f(\theta)$ be LEBESGUE INTEGRABLE and let

$$f(r,\theta) = \frac{1}{2\pi}\int_{-\pi}^{\pi} f(t)\frac{1-r^2}{1-2r\cos(t-\theta)+r^2}\,dt \qquad (1)$$

be the corresponding POISSON INTEGRAL. Then ALMOST EVERYWHERE in $-\pi \leq \theta \leq \pi$

$$\lim_{r\to 0^-} f(r,\theta) = f(\theta). \qquad (2)$$

Let

$$F(z) = c_0 + c_1 z + c_2 z^2 + \ldots + c_n z^n + \ldots \qquad (3)$$

be regular for $|z| < 1$, and let the integral

$$\frac{1}{2\pi}\int_{-\pi}^{\pi}|F(re^{i\theta})|^2 d\theta \quad (4)$$

be bounded for $r < 1$. This condition is equivalent to the convergence of

$$|C_0|^2+|C_1|^2+\ldots+|C_n|^2+\ldots \quad (5)$$

Then almost everywhere in $-\pi \leq \theta \leq \pi$,

$$\lim_{r\to 0^-} F(re^{i\theta}) = F(e^{i\theta}). \quad (6)$$

Furthermore, $F(e^{i\theta})$ is measurable, $|F(e^{i\theta})|^2$ is LEBESGUE INTEGRABLE, and the FOURIER SERIES of $F(e^{i\theta})$ is given by writing $z = e^{i\theta}$.

Faulhaber's Formula

In a 1631 edition of *Academiae Algebrae*, J. Faulhaber published the general formula for the POWER SUM of the first n POSITIVE INTEGERS,

$$\sum_{k=1}^{n} k^p = \frac{1}{p+1}\sum_{i=1}^{p+1}(-1)^{\delta_{ip}}\binom{p+1}{i}B_{p+1-i}n^i, \quad (1)$$

where δ_{ip} is the KRONECKER DELTA, $\binom{n}{i}$ is a BINOMIAL COEFFICIENT, and B_i is the ith BERNOULLI NUMBER. Computing the sums for $p = 1, \ldots, 10$ gives

$$\sum_{k=1}^{n} k = \frac{1}{2}(n^2+n) \quad (2)$$

$$\sum_{k=1}^{n} k^2 = \frac{1}{6}(2n^3+3n^2+n) \quad (3)$$

$$\sum_{k=1}^{n} k^3 = \frac{1}{4}(n^4+2n^3+n^2) \quad (4)$$

$$\sum_{k=1}^{n} k^4 = \frac{1}{30}(6n^5+15n^4+10n^3-n) \quad (5)$$

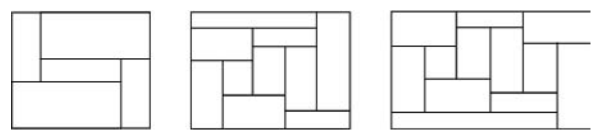
$$\sum_{k=1}^{n} k^5 = \frac{1}{12}(2n^6+6n^5+5n^4-n^2) \quad (6)$$

$$\sum_{k=1}^{n} k^6 = \frac{1}{42}(6n^7+21n^6+21n^5-7n^3+n) \quad (7)$$

$$\sum_{k=1}^{n} k^7 = \frac{1}{24}(3n^8+12n^7+14n^6-7n^4+2n^2) \quad (8)$$

$$\sum_{k=1}^{n} k^8 = \frac{1}{90}(10n^9+45n^8+60n^7-42n^5+20n^3-3n) \quad (9)$$

$$\sum_{k=1}^{n} k^9 = \frac{1}{20}(2n^{10}+10n^9+15n^8-14n^6+10n^4-3n^2) \quad (10)$$



$$\sum_{k=1}^{n} k^{10} = \frac{1}{66}(6n^{11}+33n^{10}+55n^9-66n^5-33n^3+5n). \quad (11)$$

Favard Constants

N.B. A detailed online essay by S. Finch was the starting point for this entry.

Let $T_n(x)$ be an arbitrary trigonometric POLYNOMIAL

$$T_n(x) = \frac{1}{2}a_0 + \left\{\sum_{k=1}^{n}[a_k\cos(kx)+b_k\sin(kx)]\right\}, \quad (1)$$

where the COEFFICIENTS are real. Let the rth derivative of $T_n(x)$ be bounded in $[-1, 1]$, then there exists a POLYNOMIAL $T_n(x)$ for which

$$|f(x)-T_n(x)| \leq \frac{K_r}{(n+1)^r}, \quad (2)$$

for all x, where K_r is the rth Favard constant, which is the smallest constant possible,

$$K_r = \frac{4}{\pi}\sum_{k=0}^{\infty}\left[\frac{(-1)^k}{2k+1}\right]^{r+1}, \quad (3)$$

which can be written in terms of the LERCH TRANSCENDENT as

$$K_r = 2^{-(r+1)}\Phi\left((-1)^{r+1}, r+1, \frac{1}{2}\right). \quad (4)$$

These can be expressed by

$$K_r = \begin{cases} \frac{4}{\pi}\lambda(r+1) & \text{for r odd} \\ \frac{4}{\pi}\beta(r+1) & \text{for r even,} \end{cases} \quad (5)$$

where $\lambda(x)$ is the DIRICHLET LAMBDA FUNCTION and $\beta(x)$ is the DIRICHLET BETA FUNCTION. Explicitly,

$$K_0 = 1$$

$$K_1 = \frac{1}{2}\pi$$

$$K_2 = \frac{1}{8}\pi^2$$

$$K_3 = \frac{1}{24}\pi^3$$

$$K_4 = \frac{5}{384}\pi^4$$

$$K_5 = \frac{1}{240}\pi^5$$

(Sloane's A050970 and A050971).

F-Distribution

A continuous statistical distribution which arises in the testing of whether two observed samples have the same VARIANCE. Let χ_m^2 and χ_n^2 be independent variates distributed as CHI-SQUARED with m and n DEGREES OF FREEDOM. Define a statistic $F_{n,m}$ as the ratio of the dispersions of the two distributions

$$F_{n,m} \equiv \frac{\chi_n^2/n}{\chi_m^2/m}. \quad (1)$$

This statistic then has an F-distribution with probability function $f_{n,m}(x)$ and cumulative distribution function $F_{n,m}(x)$ given by

$$f_{n,m}(x) = \frac{\Gamma\left(\frac{n+m}{2}\right) n^{n/2} m^{m/2}}{\Gamma\left(\frac{n}{2}\right)\Gamma\left(\frac{m}{2}\right)} \frac{x^{n/2-1}}{(m+nx)^{(n+m)/2}} \quad (2)$$

$$= \frac{m^{m/2} n^{n/2} x^{n/2-1}}{(m+nx)^{(n+m)/2} B\left(\frac{1}{2}n, \frac{1}{2}m\right)} \quad (3)$$

$$F_{n,m}(x) = I\left(1; \frac{1}{2}m, \frac{1}{2}n\right) - I\left(\frac{m}{m+nx}; \frac{1}{2}m, \frac{1}{2}n\right), \quad (4)$$

where $\Gamma(z)$ is the GAMMA FUNCTION, $B(a, b)$ is the BETA FUNCTION, and $I(x; a, b)$ is the REGULARIZED BETA FUNCTION. The MEAN, VARIANCE, SKEWNESS and KURTOSIS are

$$\mu = \frac{m}{m-2} \quad (5)$$

$$\sigma^2 = \frac{2m^2(m+n-2)}{n(m-2)^2(m-4)} \quad (6)$$

$$\gamma_1 = \frac{2(m+2n-2)}{m-6}\sqrt{\frac{2(m-4)}{n(m+n-2)}} \quad (7)$$

$$\gamma_2 = \frac{12(-16+20m-8m^2+m^3+44n)}{n(m-6)(m-8)(n+m-2)} + \frac{12(-32mn+5m^2n-22n^2+5mn^2)}{n(m-6)(m-8)(n+m-2)}. \quad (8)$$

The probability that F would be as large as it is if the first distribution has a smaller variance than the second is denoted $Q(F_{n,m})$.

The noncentral F-distribution is given by

$$P(x) = e^{-\lambda/2+(\lambda n_1 x)/[2(n_2+n_1 x)]} n_1^{n_1/2} n_2^{n_2/2} x^{n_1/2-1} \times (n_2+n_1 x)^{-(n_1+n_2)/2} \times \frac{\Gamma\left(\frac{1}{2}n_1\right)\Gamma\left(1+\frac{1}{2}n_2\right) L_{n_2/2}^{n_1/2-1}\left(-\frac{\lambda n_1 x}{2(n_2+n_1 x)}\right)}{B\left(\frac{1}{2}n_1, \frac{1}{2}n_2\right)\Gamma\left[\frac{1}{2}(n_1+n_2)\right]}, \quad (9)$$

where $\Gamma(z)$ is the GAMMA FUNCTION, $B(\alpha, \beta)$ is the BETA FUNCTION, and $L_m^n(z)$ is an associated LAGUERRE POLYNOMIAL.

Feigenbaum Constant

A universal constant for functions approaching CHAOS via period doubling. It was discovered by Feigenbaum in 1975 and demonstrated rigorously by Lanford (1982) and Collet and Eckmann (1979, 1980). The Feigenbaum constant δ characterizes the geometric approach of the bifurcation parameter to its limiting value. Let μ_k be the point at which a period 2^k cycle becomes unstable. Denote the converged value by μ_∞. Assuming geometric convergence, the difference between this value and μ_k is denoted

$$\lim_{k\to\infty} \mu_\infty - \mu_k = \frac{\Gamma}{\delta^k}, \tag{1}$$

where Γ is a constant and δ is a constant > 1. Solving for δ gives

$$\delta = \lim_{n\to\infty} \frac{\mu_{n+1} - \mu_n}{\mu_{n+2} - \mu_{n+1}} \tag{2}$$

(Rasband 1990, p. 23). For the LOGISTIC EQUATION,

$$\delta = 4.669201609102990\ldots \tag{3}$$

$$\Gamma = 2.637\ldots \tag{4}$$

$$\mu_\infty = 3.5699456\ldots \tag{5}$$

Stoschek gives the approximation

$$\delta = 4\frac{1 + \frac{12^2}{163} + \frac{4.12^2 + 31}{4.163^2} + \ldots}{1 + \frac{10^2}{163} + \frac{10^2 + 30}{163^2} + \ldots} \tag{6}$$

$$\approx 4.66920160933975.$$

Amazingly, the Feigenbaum constant $\delta \approx 4.669$ is "universal" (i.e., the same) for all 1-D MAPS $f(x)$ if $f(x)$ has a single locally quadratic MAXIMUM. More specifically, the Feigenbaum constant is universal for 1-D MAPS if the SCHWARZIAN DERIVATIVE

$$D_{\text{Schwarzian}} = \frac{f'''(x)}{f'(x)} - \frac{3}{2}\left[\frac{f''(x)}{f'(x)}\right]^2 \tag{7}$$

is NEGATIVE in the bounded interval (Tabor 1989, p. 220). Examples of maps which are universal include the HÉNON MAP, LOGISTIC MAP, LORENZ SYSTEM, Navier-Stokes truncations, and sine map $x_{n+1} = a\sin(\pi x_n)$. The value of the Feigenbaum constant can be computed explicitly using functional group renormalization theory. The universal constant also occurs in phase transitions in physics and, curiously, is very nearly equal to

$$\pi + \tan^{-1}(e^\pi) = 4.669201932\ldots \tag{8}$$

For an AREA-PRESERVING 2-D MAP with

$$x_{n+1} = f(x_n, y_n) \tag{9}$$

$$y_{n+1} = g(x_n, y_n), \tag{10}$$

the Feigenbaum constant is $\delta = 8.7210978\ldots$ (Tabor 1989, p. 225). For a function OF THE FORM

$$f(x) = 1 - a|x|^n \tag{11}$$

with a and n constant and n an INTEGER, the Feigenbaum constant for various n is given in the following table (Briggs 1991, Briggs *et al.* 1991, Finch), which updates the values in Tabor (1989, p. 225).

n	δ	α
3	5.9679687038...	1.9276909638...
4	7.2846862171...	1.6903029714...
5	8.3494991320...	1.5557712501...
6	9.2962468327...	1.4677424503...

An additional constant α, defined as the separation of adjacent elements of PERIOD DOUBLED ATTRACTORS from one double to the next, has a value

$$\lim_{n\to\infty} \frac{d_n}{d_n + 1} \equiv -\alpha = -2.502907875\ldots \tag{12}$$

for "universal" maps (Rasband 1990, p. 37). This value may be approximated from functional group renormalization theory to the zeroth order by

$$1 - \alpha^{-1} = \frac{1 - \alpha^{-2}}{[1 - \alpha^{-2}(1 - \alpha^{-1})]^2}, \tag{13}$$

which, when the QUINTIC EQUATION is numerically solved, gives $\alpha = -2.48634\ldots$, only 0.7% off from the actual value (Feigenbaum 1988).

Feigenbaum Function

Consider an arbitrary 1-D MAP

$$x_{n+1} = F(x_n) \tag{1}$$

at the onset of CHAOS. After a suitable rescaling, the Feigenbaum function

$$g(x) = \lim_{n\to\infty} \frac{1}{F^{(2^n)}(0)} F^{(2^n)}\left(xF^{(2^n)}(0)\right) \tag{2}$$

is obtained. This function satisfies

$$g(g(x)) = -\frac{1}{\alpha} g(\alpha x), \tag{3}$$

with $\alpha = 2.50290\ldots$, a quantity related to the FEIGENBAUM CONSTANT.

Feit-Thompson Conjecture

The conjecture that there are no PRIMES p and q for which $(p^q-1)/(p-1)$ and $(q^p-1)/(q-1)$ have a common factor. Parker noticed that if this were true, it would greatly simplify the lengthy proof of the FEIT-THOMPSON THEOREM (Guy 1994, p. 81). However, the counterexample $(p=17, q=3313)$ with a common factor 112,643 was subsequently found by Stephens (1971). There are no other such pairs with both values less than 400,000.

Feller's Coin-Tossing Constants

COIN TOSSING

Feller-Lévy Condition

Given a sequence of independent random variates X_1, X_2, ..., if $\sigma_k^2 = \text{var}(X_k)$ and

$$\rho_n^2 \equiv \max_{k \leq n} \left(\frac{\sigma_k^2}{s_n^2} \right),$$

then

$$\lim_{n \to \infty} \rho_n^2 = 0.$$

This means that if the LINDEBERG CONDITION holds for the sequence of variates X_1, ..., then the VARIANCE of an individual term in the sum S_n of X_k is asymptotically negligible. For such sequences, the LINDEBERG CONDITION is NECESSARY as well as SUFFICIENT for the LINDEBERG-FELLER CENTRAL LIMIT THEOREM to hold.

Ferguson-Forcade Algorithm

The first practical algorithm for determining if there exist integers a_i for given real numbers x_i such that

$$a_1 x_1 + a_2 x_2 + \ldots + a_n x_n = 0,$$

or else establish bounds within which no such INTEGER RELATION can exist (Ferguson and Forcade 1979). The algorithm therefore became the first viable generalization of the EUCLIDEAN ALGORITHM to $n \geq 3$ variables.

A nonrecursive variant of the original algorithm was subsequently devised by Ferguson (1987). The Ferguson-Forcade algorithm has been shown to be polynomial-time in the logarithm in the size of a smallest relation, but has not been shown to be polynomial in dimension (Ferguson *et al.* 1999).

Fermat 4n+1 Theorem

Every PRIME p OF THE FORM $p = 4n + 1$ is a sum of two SQUARE NUMBERS in one unique way (up to the order of SUMMANDS). The theorem was stated by Fermat, but the first published proof was by Euler.

The first few primes p which are 1 or 2 (mod 4) are 2, 5, 13, 17, 29, 37, 41, 53, 61, ... (Sloane's A002313) (with the only prime congruent to 2 mod 4 being 2). The numbers (x, y) such that $x^2 + y^2$ equal these primes are (1, 1), (1, 2), (2, 3), (1, 4), (2, 5), (1, 6), ... (Sloane's A002331 and A002330).

Fermat Compositeness Test

The COMPOSITENESS TEST consisting of the application of FERMAT'S LITTLE THEOREM

Fermat Conic

A PLANE CURVE OF THE FORM $y = x^n$. For $n > 0$, the curve is a generalized PARABOLA; for $n < 0$ it is a generalized HYPERBOLA.

See also CONIC SECTION, HYPERBOLA, PARABOLA

Fermat Difference Equation

PELL EQUATION

Fermat Diophantine Equation

PELL EQUATION

Fermat Elliptic Curve Theorem

The only whole number solution to the DIOPHANTINE EQUATION

$$y^3 = x^2 + 2$$

is $y = 3$, $x = \pm 5$. This theorem was offered as a problem by Fermat , who suppressed his own proof.

Fermat Equation

The DIOPHANTINE EQUATION

$$x^n + y^n = z^n.$$

The assertion that this equation has no nontrivial solutions for $n > 2$ has a long and fascinating history and is known as FERMAT'S LAST THEOREM.

See also FERMAT'S LAST THEOREM

Fermat Number

A BINOMIAL NUMBER OF THE FORM $F_n = 2^{2^n} + 1$. The first few for $n = 0, 1, 2, ...$ are 3, 5, 17, 257, 65537, 4294967297, ... (Sloane's A000215). The number of DIGITS for a Fermat number is

$$D(n) = \lfloor [\log(2^{2^n} + 1)] + 1 \rfloor \approx \lfloor \log(2^{2^n}) + 1 \rfloor = \lfloor 2^n \log 2 + 1 \rfloor. \quad (1)$$

Being a Fermat number is the NECESSARY (but not SUFFICIENT) form a number

$$N_n \equiv 2^n + 1 \quad (2)$$

must have in order to be PRIME. This can be seen by noting that if $N_n = 2^n + 1$ is to be PRIME, then n cannot have any ODD factors b or else N_n would be a factorable number OF THE FORM

$$2^n + 1 = (2^a)^b + 1 = (2^a + 1) \times [2^{a(b-1)} - 2^{a(b-2)} + 2^{a(b-3)} - \ldots + 1]. \quad (3)$$

Therefore, for a PRIME N_n, n must be a POWER of 2. No two Fermat numbers have a common divisor greater than 1 (Hardy and Wright 1979, p. 14).

Fermat conjectured in 1650 that every Fermat number is PRIME and Eisenstein (1844) proposed as a problem the proof that there are an infinite number of Fermat primes (Ribenboim 1996, p. 88). At present, however, only COMPOSITE Fermat numbers F_n are known for $n \geq 5$. An anonymous writer proposed that numbers OF THE FORM $2^2 + 1$, $2^{2^2} + 1$, $2^{2^{2^2}} + 1$ were PRIME. However, this conjecture was refuted when Selfridge (1953) showed that

$$F_{16} = 2^{2^{16}} + 1 = 2^{2^{2^{2^2}}} + 1 \quad (4)$$

is COMPOSITE (Ribenboim 1996, p. 88). Numbers OF THE FORM $a^{2^n} + b^{2^n}$ are called generalized Fermat numbers (Ribenboim 1996, pp. 359–60).

Fermat numbers satisfy the RECURRENCE RELATION

$$F_m = F_0 F_1 \ldots F_{m-1} + 2. \quad (5)$$

F_n can be shown to be PRIME IFF it satisfies PÉPIN'S TEST

$$3^{(F_n-1)/2} \equiv -1 \pmod{F_n}. \quad (6)$$

PÉPIN'S THEOREM

$$3^{2^{2^n-1}} \equiv -1 \pmod{F_n} \quad (7)$$

is also NECESSARY and SUFFICIENT.

In 1770, Euler showed that any FACTOR of F_n must have the form

$$2^{n+1}K+1, \quad (8)$$

where K is a POSITIVE INTEGER. In 1878, Lucas increased the exponent of 2 by one, showing that FACTORS of Fermat numbers must be OF THE FORM

$$2^{n+2}L+1. \quad (9)$$

If

$$F = p_1 p_2 \cdots p_r \quad (10)$$

is the factored part of $F_n = FC$ (where C is the cofactor to be tested for primality), compute

$$A \equiv 3^{F_n-1} \pmod{F_n} \quad (11)$$

$$B \equiv 3^{F-1} \pmod{F_n} \quad (12)$$

$$R \equiv A - B \pmod{C}. \quad (13)$$

Then if $R \equiv 0$, the cofactor is a PROBABLE PRIME to the base 3^F;; otherwise C is COMPOSITE.

In order for a POLYGON to be circumscribed about a CIRCLE (i.e., a CONSTRUCTIBLE POLYGON), it must have a number of sides N given by

$$N = 2^k F_0 \cdots F_n, \quad (14)$$

where the F_n are *distinct* Fermat primes (as stated by Gauss and first published by Wantzel 1836). This is equivalent to the statement that the trigonometric functions $\sin(k\pi/N)$, $\cos(k\pi/N)$, etc., can be computed in terms of finite numbers of additions, multiplications, and square root extractions IFF N is of the above form. The only known Fermat PRIMES are

$$F_0 = 3$$

$$F_1 = 5$$

$$F_2 = 17$$

$$F_3 = 257$$

$$F_4 = 65537$$

and it seems unlikely that any more exist.

Factoring Fermat numbers is extremely difficult as a result of their large size. In fact, only F_5 to F_{11} have been complete factored, as summarized in the following table. Written out explicitly, the complete factorizations are

$$F_5 = 641 \cdot 6700417$$

$$F_6 = 274177 \cdot 67280421310721$$

$$F_7 = 59649589127497217 \cdot 5704689200685129054721$$

$$F_8 = 1238926361552897 \cdot 93461639715357977769163 \cdots$$
$$\cdots 558199606896584051237541638188580280321$$

$$F_9 = 2424833 \cdot 7455602825647884208337395736200 4 \cdots$$
$$\cdots 54918783366342657 \cdot P99$$

$$F_{10} = 45592577 \cdot 6487031809 \cdot 46597757852200185 \cdots$$
$$\cdots 43264560743076778192897 \cdot P252$$

$$F_{11} = 319489 \cdot 974849 \cdot 167988556341760475137$$
$$\cdot 3560841906445833920513 \cdot P564.$$

Here, the final large PRIME is not explicitly given since it can be computed by dividing F_n by the other given factors.

The following table summarizes the properties of completely factored Fermat numbers.

F_n	Digits	Factors	Digits	Reference
5	10	2	3, 7	Euler 1732
6	20	2	6, 14	Landry 1880
7	39	2	7, 22	Morrison and Brillhart 1975
8	78	2	16, 62	Brent and Pollard 1981
9	155	3	7, 49, 99	Manasse and Lenstra (In Cipra 1993)
10	309	4	8, 10, 40, 252	Brent 1995
11	617	5	6, 6, 21, 22, 564	Brent 1988

Tables of known factors of Fermat numbers are given by Keller (1983), Brillhart *et al.* (1988), Young and Buell (1988), Riesel (1994), and Pomerance (1996). Young and Buell (1988) discovered that F_{20} is COMPOSITE, and Crandall *et al.* (1995) that F_{22} is COMPOSITE. In 1999, Crandall *et al.* showed that F_{24} is COMPOSITE. A current list of the known factors of Fermat numbers is maintained by Keller, and reproduced in the form of a *Mathematica* notebook by Weisstein. In these tables, since all factors are OF THE FORM $k2^n+1$, the known factors are expressed in the concise form (k, n). The number of factors for Fermat

numbers F_n for $n = 0, 1, 2, ...$ are 1, 1, 1, 1, 1, 2, 2, 2, 2, 3, 4, 5, ...

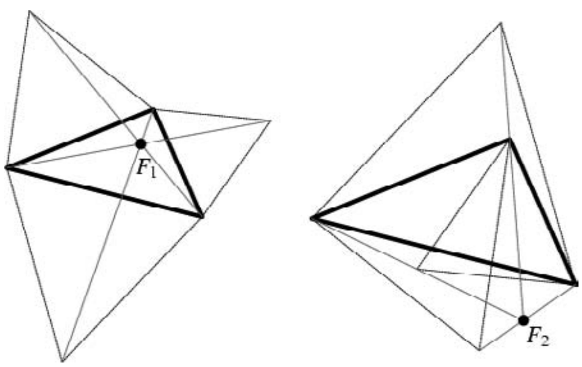
Fermat Number (Lucas)

A number OF THE FORM $2^n - 1$ obtained by setting $x = 1$ in a FERMAT POLYNOMIAL is called a MERSENNE NUMBER.



See also FERMAT-LUCAS NUMBER, MERSENNE NUMBER

Fermat Points

In a given ACUTE TRIANGLE ΔABC, the Fermat point X (or "first Fermat point" F_1, also called the Torricelli point) is the point which minimizes the sum of distances from A, B, and C,

$$|AX|+|BX|+|CX|. \tag{1}$$

This problem is called FERMAT'S PROBLEM or STEINER'S PROBLEM (Courant and Robbins 1941) and was proposed by Fermat to Torricelli. Torricelli's solution was published by his pupil Viviani in 1659 (Johnson 1929).

If all ANGLES of the TRIANGLE are less than 120° $(2\pi/3)$, then the Fermat point is the interior point X from which each side subtends an ANGLE of 120°, i.e.,

$$\angle BXC = \angle CXA = \angle AXB = 120^\circ. \tag{2}$$

The Fermat point can be constructed by drawing EQUILATERAL TRIANGLES on the outside of the given TRIANGLE and connecting opposite VERTICES. The three diagonals in the figure then intersect in the Fermat point. Similarly, the second Fermat point F_2 is constructed using equilateral triangles pointing inwards. The Fermat points are also known as the isogonic centers, since they are ISOGONAL CONJUGATES of the ISODYNAMIC POINTS.

The TRIANGLE CENTER FUNCTIONS of the Fermat points are

$$\alpha_1 = \csc\left(A + \frac{1}{3}\pi\right) \tag{3}$$

$$bc\left[c^2a^2 + (c^2 + a^2 - b^2)^2\right]\left[a^2b^2 - (a^2 + b^2 - c^2)^2\right] \times \left[4\Delta - \sqrt{3}(b^2 + c^2 - d^2)\right] \tag{4}$$

$$\alpha_2 = \csc\left(A - \frac{1}{3}\pi\right) \tag{5}$$

The ANTIPEDAL TRIANGLE of F_1 is EQUILATERAL and has AREA

$$\Delta' = 2\Delta\left[1 + \cot\omega\cot\left(\frac{\pi}{3}\right)\right], \tag{6}$$

where ω is the BROCARD ANGLE. The ANTIPEDAL TRIANGLE of F_2 is also an EQUILATERAL and has AREA

$$2\Delta = \left[-1 + \cot\omega\cot\left(\frac{1}{3}\pi\right)\right]. \tag{7}$$

Given three POSITIVE REAL NUMBERS l, m, n, the "generalized" Fermat point is the point P of a given ACUTE TRIANGLE ΔABC such that

$$l\cdot PA + m\cdot PB + n\cdot PC \tag{8}$$

is a minimum (Greenberg and Robertello 1965, van de Lindt 1966, Tong and Chua 1995)

Fermat Polynomial

The POLYNOMIALS obtained by setting $p(x) = 3x$ and $q(x) = -2$ in the LUCAS POLYNOMIAL SEQUENCES. The first few Fermat polynomials are

$$\mathcal{F}(x) = 1$$

$$\mathcal{F}_2(x) = 3x$$

$$\mathcal{F}_3(x) = 9x^2 - 2$$

$$\mathcal{F}_4(x) = 27x^3 - 12x$$

$$\mathscr{F}_5(x) = 81x^4 - 54x^2 + 4,$$

and the first few Fermat-Lucas polynomials are

$$f_1(x) = 3x$$

$$f_2(x) = 9x^2 - 4$$

$$f_3 = 27x^3 - 18x$$

$$f_4(x) = 81x^4 - 72x^2 + 8$$

$$f_5(x) = 243x^5 - 270x^3 + 60x.$$

Fermat and Fermat-Lucas POLYNOMIALS satisfy

$$\mathscr{F}_n(1) = \mathscr{F}_n$$

$$f_n(1) = f_n$$

where $\mathscr{F}_n$ are FERMAT NUMBERS and f_n are FERMAT-LUCAS NUMBERS.

Fermat Prime

A FERMAT NUMBER $F_n = 2^{2n} + 1$ which is PRIME.

See also CONSTRUCTIBLE POLYGON, FERMAT NUMBER

Fermat Pseudoprime

A Fermat pseudoprime to a base a, written psp(a), is a COMPOSITE NUMBER n such that $a^{n-1} \equiv 1 \pmod{n}$ (i.e., it satisfies FERMAT'S LITTLE THEOREM, sometimes with the requirement that n must be ODD; Pomerance *et al.* 1980). psp(2)s are called POULET NUMBERS or, less commonly, SARRUS NUMBERS or FERMATIANS (Shanks 1993). The first few EVEN psp(2)s (including the PRIME 2 as a pseudoprime) are 2, 161038, 215326, ... (Sloane's A006935).

If base 3 is used in addition to base 2 to weed out potential COMPOSITE NUMBERS, only 4709 COMPOSITE NUMBERS remain $< 25 \times 10^9$. Adding base 5 leaves 2552, and base 7 leaves only 1770 COMPOSITE NUMBERS.

Fermat Quotient

The Fermat quotient for a number a and a PRIME base p is defined as

$$q_p(a) \equiv \frac{a^{p-1} - 1}{p}. \tag{1}$$

If $p \nmid ab$, then

$$q_p(ab) = q_p(a) + q_p(b) \tag{2}$$

$$q_p(p \pm 1) = \mp 1 \tag{3}$$

$$q_p(2) = \frac{1}{p}\left(1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots - \frac{1}{p-1}\right) \tag{4}$$

all (mod p). The quantity $q_p(2) = (2^{p-1} - 1)/p$ is known to be SQUARE for only two PRIMES: the so-called WIEFERICH PRIMES 1093 and 3511 (Lehmer 1981, Crandall 1986).

Fermat's Algorithm

FERMAT'S FACTORIZATION METHOD

Fermat's Congruence

FERMAT'S LITTLE THEOREM

Fermat's Conjecture

FERMAT'S LAST THEOREM

Fermat's Divisor Problem

In 1657, Fermat posed the problem of finding solutions to

$$\sigma(x^3) = y^2 \tag{1}$$

and

$$\sigma(x^2) = y^3, \tag{2}$$

where $\sigma(n)$ is the DIVISOR FUNCTION (Dickson 1952).

The first few solutions to $\sigma(x^3) = y^2$ are $(x, y) = (1, 1)$, (7, 20), (751530, 1292054400) (Sloane's A008849 and A048948) .... Lucas stated that there are an infinite

number of solutions (Dickson 1952, p. 56), but only solutions up to the fourth are known to be complete.

The first few solutions to $\sigma(x^2)=y^3$ are $(x,y)=(1,1)$, (43098, 1729), ... (Sloane's A008850 and A048949), with only solutions up to the second known to be complete.

Fermat's Factorization Method

Given a number n, look for INTEGERS x and y such that $n=x^2-y^2$. Then

$$n=(x-y)(x+y) \tag{1}$$

and n is factored. Any ODD NUMBER can be represented in this form since then $n = ab$, a and b are ODD, and

$$a=x+y \tag{2}$$

$$b=x-y. \tag{3}$$

Adding and subtracting,

$$a+b=2x \tag{4}$$

$$a-b=2y, \tag{5}$$

so solving for x and y gives

$$x=\frac{1}{2}(a+b) \tag{6}$$

$$y=\frac{1}{2}(a-b). \tag{7}$$

Therefore,

$$x^2-y^2=\frac{1}{4}\left[(a+b)^2-(a-b)^2\right]=ab. \tag{8}$$

As the first trial for x, try $x_1\lceil\sqrt{n}\rceil$, where $\lceil x\rceil$ is the CEILING FUNCTION. Then check if

$$\Delta x_1=x_1^2-n \tag{9}$$

is a SQUARE NUMBER. There are only 22 combinations of the last two digits which a SQUARE NUMBER can assume, so most combinations can be eliminated. If Δx_1 is not a SQUARE NUMBER, then try

$$x_2=x_1+1, \tag{10}$$

so

$$\begin{aligned}\Delta x_2&=x_2^2-n\\&=(x_1+1)^2-n=x_1^2+2x_1+1-n\\&=\Delta x_1+2x_1+1.\end{aligned} \tag{11}$$

Continue with

$$\begin{aligned}\Delta x_3&=x_3^2-n\\&=(x_2+1)^2-n=x_2^2+2x_2+1-n=\Delta x_2+2x_2+1\\&=\Delta x_2+2x_1+3,\end{aligned} \tag{12}$$

so subsequent differences are obtained simply by adding two.

Maurice Kraitchik sped up the ALGORITHM by looking for x and y satisfying

$$x^2\equiv y^2 (\text{mod } n), \tag{13}$$

i.e., $n|(x^2-y^2)$. This congruence has uninteresting solutions $x\equiv\pm y (\text{mod } n)$ and interesting solutions $x\not\equiv\pm y (\text{mod} n)$. It turns out that if n is ODD and DIVISIBLE by at least two different PRIMES, then at least half of the solutions to $x^2\equiv y^2 (\text{mod } n)$ with xy COPRIME to n are interesting. For such solutions, $(n, x-y)$ is neither n nor 1 and is therefore a nontrivial factor of n (Pomerance 1996). This ALGORITHM can be used to prove primality, but is not practical. In 1931, Lehmer and Powers discovered how to search for such pairs using CONTINUED FRACTIONS. This method was improved by Morrison and Brillhart (1975) into the CONTINUED FRACTION FACTORIZATION ALGORITHM, which was the fastest ALGORITHM in use before the QUADRATIC SIEVE factorization method was developed.

Fermat's Last Theorem

A theorem first proposed by Fermat in the form of a note scribbled in the margin of his copy of the ancient Greek text *Arithmetica* by Diophantus. The scribbled note was discovered posthumously, and the original is now lost. However, a copy was preserved in a book published by Fermat's son. In the note, Fermat claimed to have discovered a proof that the DIOPHANTINE EQUATION $x^n+y^n=z^n$ has no INTEGER solutions for $n>2$.

The full text of Fermat's statement, written in Latin, reads "Cubum autem in duos cubos, aut quadrato-quadratum in duos quadrato-quadratos, et generaliter nullam in infinitum ultra quadratum potestatem in duos eiusdem nominis fas est dividere cuius rei demonstrationem mirabilem sane detexi. Hanc marginis exiguitas non caperet" (Nagell 1951, p. 252). In translation, "It is impossible for a cube to be the sum of two cubes, a fourth power to be the sum of two fourth powers, or in general for any number that is a power greater than the second to be the sum of two like powers. I have discovered a truly marvelous demonstration of this proposition that this margin is too narrow to contain."

As a result of Fermat's marginal note, the proposition that the DIOPHANTINE EQUATION

$$x^n + y^n = z^n, \tag{1}$$

where x, y, z, and n are INTEGERS, has no NONZERO solutions for $n > 2$ has come to be known as Fermat's Last Theorem. It was called a "THEOREM" on the strength of Fermat's statement, despite the fact that no other mathematician was able to prove it for hundreds of years.

Note that the restriction $n > 2$ is obviously necessary since there are a number of elementary formulas for generating an infinite number of PYTHAGOREAN TRIPLES (x, y, z) satisfying the equation for $n = 2$,

$$x^2 + y^2 = z^2. \tag{2}$$

A first attempt to solve the equation can be made by attempting to factor the equation, giving

$$\left(z^{n/2} + y^{n/2}\right)\left(z^{n/2} - y^{n/2}\right) = x^n. \tag{3}$$

Since the product is an exact POWER,

$$\begin{cases} z^{n/2} + y^{n/2} = 2^{n-1}p^n \\ z^{n/2} - y^{n/2} = 2q^n \end{cases} \quad \text{or} \quad \begin{cases} z^{n/2} + y^{n/2} = 2p^n \\ z^{n/2} - y^{n/2} = 2^{n-1}q^n. \end{cases} \tag{4}$$

Solving for y and z gives

$$\begin{cases} z^{n/2} = 2^{n-2}p^n + q^n \\ y^{n/2} = 2^{n-2}p^n - q^n \end{cases} \quad \text{or} \quad \begin{cases} z^{n/2} = p^n + 2^{n-2}q^n \\ y^{n/2} = p^n - 2^{n-2}q^n, \end{cases} \tag{5}$$

which give

$$\begin{cases} z = \left(2^{n-2}p^n + q^n\right)^{2/n} \\ y = \left(2^{n-2}p^n - q^n\right)^{2/n} \end{cases} \quad \text{or} \quad \begin{cases} z = \left(p^n + 2^{n-2}q^n\right)^{2/n} \\ y = \left(p^n - 2^{n-2}q^n\right)^{2/n}. \end{cases} \tag{6}$$

However, since solutions to these equations in RATIONAL NUMBERS are no easier to find than solutions to the original equation, this approach unfortunately does not provide any additional insight.

It is sufficient to prove Fermat's Last Theorem by considering PRIME POWERS only, since the arguments can otherwise be written

$$(x^m)^p + (y^m)^p = (z^m)^p, \tag{7}$$

so redefining the arguments gives

$$z^p + y^p = z^p. \tag{8}$$

The so-called "first case" of the theorem is for exponents which are RELATIVELY PRIME to x, y, and z ($p \nmid x, y, z$) and was considered by Wieferich. Sophie Germain proved the first case of Fermat's Last Theorem for any ODD PRIME p when $2p+1$ is also a PRIME. Legendre subsequently proved that if p is a PRIME such that $4p+1$, $8p+1$, $10p+1$, $14p+1$, or $16p+1$ is also a PRIME, then the first case of Fermat's Last Theorem holds for p. This established Fermat's Last Theorem for $p < 100$. In 1849, Kummer proved it for all REGULAR PRIMES and COMPOSITE NUMBERS of which they are factors (Vandiver 1929, Ball and Coxeter 1987).

Kummer's attack led to the theory of IDEALS, and Vandiver developed VANDIVER'S CRITERIA for deciding if a given IRREGULAR PRIME satisfies the theorem. Genocchi (1852) proved that the first case is true for p if $(p, p-3)$ is not an IRREGULAR PAIR. In 1858, Kummer showed that the first case is true if either $(p, p-3)$ or $(p, p-5)$ is an IRREGULAR PAIR, which was subsequently extended to include $(p, p-7)$ and $(p, p-9)$ by Mirimanoff (1905). Vandiver (1920ab) pointed out gaps and errors in Kummer's memoir which, in his view, invalidate Kummer's proof of Fermat's Last Theorem for the irregular primes 37, 59, and 67, although he claims Mirimanoff's proof of FLT for exponent 37 is still valid.

Wieferich (1909) proved that if the equation is solved in integers RELATIVELY PRIME to an ODD PRIME p, then

$$2^{p-1} \equiv 1 \pmod{p^2}. \tag{9}$$

(Ball and Coxeter 1987). Such numbers are called WIEFERICH PRIMES. Mirimanoff (1909) subsequently showed that

$$3^{p-1} \equiv 1 \pmod{p^2} \tag{10}$$

must also hold for solutions RELATIVELY PRIME to an ODD PRIME p, which excludes the first two WIEFERICH PRIMES 1093 and 3511. Vandiver (1914) showed

$$5^{p-1} \equiv 1 \pmod{p^2}, \tag{11}$$

and Frobenius extended this to

$$11^{p-1}, 17^{p-1} \equiv 1 \pmod{p^2}. \tag{12}$$

It has also been shown that if p were a PRIME OF THE FORM $6x-1$, then

$$7^{p-1}, 13^{p-1}, 19^{p-1} \equiv 1 \pmod{p^2}, \tag{13}$$

which raised the smallest possible p in the "first case" to 253,747,889 by 1941 (Rosser 1941). Granville and Monagan (1988) showed if there exists a PRIME p satisfying Fermat's Last Theorem, then

$$q^{p-1} \equiv 1 \pmod{p^2} \qquad (14)$$

for $q = 5, 7, 11, ..., 71$. This establishes that the first case is true for all PRIME exponents up to 714,591,416,091,398 (Vardi 1991).

The "second case" of Fermat's Last Theorem (for $p|x,y,z$) proved harder than the first case.

Euler proved the general case of the theorem for $n=3$, Fermat $n=4$, Dirichlet and Lagrange $n=5$. In 1832, Dirichlet established the case $n=14$. The $n=7$ case was proved by Lamé (1839; Wells 1986, p. 70), using the identity

$$(X+Y+Z)^7-(X^7+Y^7+Z^7)=7(X+Y)(X+Z)(Y+Z) \times\left[(X^2+Y^2+Z^2+XY+XZ+YZ)^2+XYZ(X+Y+Z)\right]. \qquad (15)$$

Although some errors were present in this proof, these were subsequently fixed by Lebesgue (1840). Much additional progress was made over the next 150 years, but no completely general result had been obtained. Buoyed by false confidence after his proof that PI is TRANSCENDENTAL, the mathematician Lindemann proceeded to publish several proofs of Fermat's Last Theorem, all of them invalid (Bell 1937, pp. 464–65). A prize of 100,000 German marks, known as the Wolfskehl Prize, was also offered for the first valid proof (Ball and Coxeter 1987, p. 72; Barner 1997; Hoffman 1998, pp. 193–94 and 199).

A recent false alarm for a general proof was raised by Y. Miyaoka (Cipra 1988) whose proof, however, turned out to be flawed. Other attempted proofs among both professional and amateur mathematicians are discussed by vos Savant (1993), although vos Savant erroneously claims that work on the problem by Wiles (discussed below) is invalid. By the time 1993 rolled around, the general case of Fermat's Last Theorem had been shown to be true for all exponents up to 4×10^6 (Cipra 1993). However, given that a proof of Fermat's Last Theorem requires truth for *all* exponents, proof for any finite number of exponents does not constitute any significant progress towards a proof of the general theorem (although the fact that no counterexamples were found for this many cases is highly suggestive).

In 1993, a bombshell was dropped. In that year, the general theorem was partially proven by Andrew Wiles (Cipra 1993, Stewart 1993) by proving the SEMISTABLE case of the TANIYAMA-SHIMURA CONJECTURE. Unfortunately, several holes were discovered in the proof shortly thereafter when Wiles' approach via the TANIYAMA-SHIMURA CONJECTURE became hung up on properties of the SELMER GROUP using a tool called an EULER SYSTEM. However, the difficulty was circumvented by Wiles and R. Taylor in late 1994 (Cipra 1994, 1995ab) and published in Taylor and Wiles (1995) and Wiles (1995). Wiles' proof succeeds by (1) replacing ELLIPTIC CURVES with Galois representations, (2) reducing the problem to a CLASS NUMBER FORMULA, (3) proving that FORMULA, and (4) tying up loose ends that arise because the formalisms fail in the simplest degenerate cases (Cipra 1995a).

The proof of Fermat's Last Theorem marks the end of a mathematical era. Since virtually all of the tools which were eventually brought to bear on the problem had yet to be invented in the time of Fermat, it is interesting to speculate about whether he actually was in possession of an elementary proof of the theorem. Judging by the temerity with which the problem resisted attack for so long, Fermat's alleged proof seems likely to have been illusionary. This conclusion is further supported by the fact that Fermat searched for proofs for the cases $n=4$ and $n=5$, which would have been superfluous had he actually been in possession of a general proof.

Fermat's Lesser Theorem

FERMAT'S LITTLE THEOREM

Fermat's Little Theorem

If p is a PRIME NUMBER and a a NATURAL NUMBER, then

$$a^p \equiv a(\bmod p). \tag{1}$$

Furthermore, if $p \nmid a$ (p does not divide a), then there exists some smallest exponent d such that

$$a^d - 1 \equiv 0(\bmod p) \tag{2}$$

and d divides $p-1$. Hence,

$$a^{p-1} - 1 \equiv 0(\bmod p). \tag{3}$$

This is a generalization of the CHINESE HYPOTHESIS and a special case of EULER'S THEOREM. It is sometimes called FERMAT'S PRIMALITY TEST and is a NECESSARY but not SUFFICIENT test for primality. Although it was presumably proved (but suppressed) by Fermat, the first proof was published by Euler in 1749.

The theorem is easily proved using mathematical INDUCTION. Suppose $p|a^p - a$. Then examine

$$(a+1)^p - (a+1). \tag{4}$$

From the BINOMIAL THEOREM,

$$(a+1)^p = a^p + \binom{p}{1}a^{p-1} + \binom{p}{2}a^{p-2} + \cdots + \binom{p}{p-1}a + 1. \quad (5)$$

Rewriting,

$$(a+1)^p - a^p - 1 = \binom{p}{1}a^{p-1} + \binom{p}{2}a^{p-2} + \ldots + \binom{p}{p-1}a. \quad (6)$$

But p divides the right side, so it also divides the left side. Combining with the induction hypothesis gives that p divides the sum

$$[(a+1)^p - a^p - 1] + (a^p - a) = (a+1)^p - (a+1), \quad (7)$$

as assumed, so the hypothesis is true for any a. The theorem is sometimes called FERMAT'S SIMPLE THEOREM. WILSON'S THEOREM follows as a COROLLARY of Fermat's little theorem.

Fermat's little theorem shows that, if p is PRIME, there does not exist a base $a < p$ with $(a,p) = 1$ such that $a^{p-1} - 1$ possesses a nonzero residue modulo p. If such base a exists, p is therefore guaranteed to be composite. However, the lack of a nonzero residue in Fermat's little theorem does *not* guarantee that p is PRIME. The property of unambiguously certifying composite numbers while passing some PRIMES make Fermat's little theorem a COMPOSITENESS TEST which is sometimes called the FERMAT COMPOSITENESS TEST. A number satisfying Fermat's little theorem for some nontrivial base and which is not known to be composite is called a PROBABLE PRIME.

COMPOSITE NUMBERS known as FERMAT PSEUDOPRIMES (or sometimes simply "PSEUDOPRIMES") have zero residue for some as and so are not identified as composite. Worse still, there exist numbers known as CARMICHAEL NUMBERS (the smallest of which is 561) which give zero residue for *any* choice of the base a RELATIVELY PRIME to p. However, FERMAT'S LITTLE THEOREM CONVERSE provides a criterion for certifying the primality of a number. A table of the smallest PSEUDOPRIMES P for the first 100 bases a follows (Sloane's A007535; Beiler 1966, p. 42 with typos corrected).

a	P	a	P	a	P	a	P	a	P

Fermat's Little Theorem Converse

The converse of FERMAT'S LITTLE THEOREM is also known as LEHMER'S THEOREM. It states that, if an INTEGER x is PRIME to m and $x^{m-1} \equiv 1 \pmod{m}$ and

there is no INTEGER $e < m-1$ for which $x^e \equiv 1 \pmod{m}$, then m is PRIME. Here, x is called a WITNESS to the primality of m. This theorem is the basis for the PRATT PRIMALITY CERTIFICATE.

Fermat's Polygonal Number Theorem

In 1638, Fermat proposed that every POSITIVE INTEGER is a sum of *at most* three TRIANGULAR NUMBERS, four SQUARE NUMBERS, five PENTAGONAL NUMBERS, and n n-POLYGONAL NUMBERS. Fermat claimed to have a proof of this result, although Fermat's proof has never been found. Gauss proved the triangular case, and noted the event in his diary on July 10, 1796, with the notation

$$**\ E\Upsilon RHKA \quad num = \Delta + \Delta + \Delta.$$

This case is equivalent to the statement that every number OF THE FORM $8m+3$ is a sum of three ODD SQUARES (Duke 1997). More specifically, a number is a sum of three SQUARES IFF it is not OF THE FORM $4^b(8m+7)$ for $b \geq 0$, as first proved by Legendre in 1798.

Euler was unable to prove the square case of Fermat's theorem, but he left partial results which were subsequently used by Lagrange. The square case was finally proved by Jacobi and independently by Lagrange in 1772. It is therefore sometimes known as LAGRANGE'S FOUR-SQUARE THEOREM. In 1813, Cauchy proved the proposition in its entirety.

Fermat's Theorem

A PRIME p can be represented in an essentially unique manner in the form $x^2 + y^2$ for integral x and y IFF $p \equiv 1 \pmod 4$ or $p = 2$. It can be restated by letting

$$Q(x, y) \equiv x^2 + y^2,$$

then all RELATIVELY PRIME solutions (x, y) to the problem of representing $Q(x, y) = m$ for m any INTEGER are achieved by means of successive applications of the GENUS THEOREM and COMPOSITION THEOREM. There is an analog of this theorem for EISENSTEIN INTEGERS.

See also EISENSTEIN INTEGER, SQUARE NUMBER

Fermat's Two-Square Theorem

FERMAT'S THEOREM

Fermat-Catalan Conjecture

The conjecture that there are only finitely many triples of RELATIVELY PRIME integer powers x^p, y^q, z^r for which

$$x^p + y^q = z^r$$

with

$$\frac{1}{p} + \frac{1}{q} + \frac{1}{r} < 1.$$

Darmon and Merel (1997) have shown that there are no relatively prime solutions $(x, x, 3)$ with $x \geq 3$. Ten solutions are known,

$$1 + 2^3 = 3^2$$

$$2^5 + 7^2 = 3^4$$

$$7^3 + 13^2 = 2^9$$

$$2^7 + 17^3 = 71^2$$

$$3^5 + 11^4 = 122^2$$

$$17^7 + 76271^3 = 21063928^2$$

$$1414^3 + 2213459^2 = 65^7$$

$$9262^3 + 15312283^2 = 113^7$$

$$43^8 + 96222^3 = 30042907^2$$

$$33^8 + 1549034^2 = 15613^3$$

(Mauldin 1997).

Ferrars Diagram

FERRERS DIAGRAM

Ferrers Diagram

A Ferrers diagram represents PARTITIONS as patterns of dots, with the nth row having the same number of dots as the nth term in the PARTITION. The spelling "Ferrars" (Skiena 1990, pp. 53 and 78) is sometimes also used, and the diagram is sometimes called a graphical representation or Ferrers graph (Andrews 1998, p. 6). A Ferrers diagram of the PARTITION

$$n=a+b+\ldots+c,$$

for a list a, b, ..., c of k POSITIVE INTEGERS with $a \geq b \geq \ldots \geq c$ is therefore the arrangement of n dots or square boxes in k rows, such that the dots or boxes are left-justified, the first row is of length a, the second row is of length b, and so on, with the kth row of length c. The above diagram corresponds to one of the possible partitions of 100.

Feuerbach's Conic Theorem

The LOCUS of the centers of all CONICS through the VERTICES and ORTHOCENTER of a TRIANGLE (which are RECTANGULAR HYPERBOLAS when not degenerate), is a CIRCLE through the MIDPOINTS of the sides, the points half way from the ORTHOCENTER to the VERTICES, and the feet of the ALTITUDE.

Feuerbach's Theorem

There are two theorems commonly known as Feuerbach's theorem. The first states that CIRCLE which passes through the feet of the PERPENDICULARS dropped from the VERTICES of any TRIANGLE on the sides opposite them passes also through the MIDPOINTS of these sides as well as through the MIDPOINT of the segments which join the VERTICES to the point of intersection of the PERPENDICULAR. Such a circle is called a NINE-POINT CIRCLE.

The proposition most frequently called Feuerbach's theorem states that the NINE-POINT CIRCLE of any TRIANGLE is TANGENT internally to the INCIRCLE and TANGENT externally to the three EXCIRCLES. This theorem was first published by Feuerbach (1822). Many proofs have been given (Elder 1960), with the simplest being the one presented by McClelland (1891, p. 225) and Lachlan (1893, p. 74).

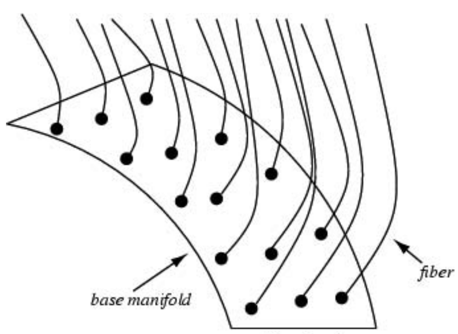
FFT

FAST FOURIER TRANSFORM

Fiber

A fiber of a map $f: X \to Y$ is the PREIMAGE of an element $y \in Y$. That is,

$$f^{-1}(y) = \{x \in X \text{ such that } f(x) = y\}.$$



For instance, let X and Y be the COMPLEX NUMBERS $\mathbb{C}$. When $f(z) = z^2$, every fiber consists of two points $\{z, -z\}$, except for the fiber over 0, which has one point. Note that a fiber may be the EMPTY SET.

In special cases, the fiber may be independent, in some sense, of the choice of $y \in Y$. For instance, if f is a COVERING MAP, then the fibers are all DISCRETE and have the same CARDINALITY. The example $f(z) = z^2$ is a covering map away from zero, i.e., $f(z) = z^2$ from the punctured plane $\mathbb{C} - \{0\}$ to itself has a fiber consisting of two points.

When $\pi : E \to M$ is a FIBER BUNDLE, then every fiber is ISOMORPHIC, in whatever CATEGORY is being used. For instance, when E is a REAL VECTOR BUNDLE of RANK k, every fiber is isomorphic to $\mathbb{R}^k$.

See also COMPLEX NUMBER, COVERING MAP, FIBER BUNDLE, MAP, RANK (BUNDLE), WHITNEY SUM

Fiber Bundle

A fiber bundle (also called simply a BUNDLE) with FIBER F is a MAP $f : E \to B$ where E is called the TOTAL SPACE of the fiber bundle and B the BASE SPACE of the fiber bundle. The main condition for the MAP to be a fiber bundle is that every point in the BASE SPACE $b \in B$ has a NEIGHBORHOOD U such that $f^{-1}(U)$ is HOMEOMORPHIC to $U \times F$ in a special way. Namely, if

$$h : f^{-1}(U) \to U \times F$$

is the HOMEOMORPHISM, then

$$\text{proj}_U \circ h = f_{|f^{-1}(U)|},$$

where the MAP proj_U means projection onto the U component. The homeomorphisms h which "commute with projection" are called local TRIVIALIZATIONS for the fiber bundle f. In other words, E looks like the product $B \times F$ (at least locally), except that the fibers $f^{-1}(x)$ for $x \in B$ may be a bit "twisted."

A fiber bundle is the most general kind of BUNDLE. Special cases are often described by replacing the word "fiber" with a word that describes the fiber being used, e.g., VECTOR BUNDLES and PRINCIPAL BUNDLES.

Examples of fiber bundles include any product $B \times F \to B$ (which is a bundle over B with FIBER F), the MÖBIUS STRIP (which is a fiber bundle over the CIRCLE with FIBER given by the unit interval [0,1]; i.e, the BASE SPACE is the CIRCLE), and $\mathbb{S}^3$ (which is a bundle over $\mathbb{S}^2$ with fiber $\mathbb{S}^1$). A special class of fiber bundle is the VECTOR BUNDLE, in which the FIBER is a VECTOR SPACE. A basic example of a nontrivial bundle is the MÖBIUS STRIP, which is a fiber bundle with the circle as its base, $B = \mathbb{S}^{-1}$, and the interval $F = (-1, 1)$ as its fiber.

Some of the properties of graphs of functions $f : B \to F$ carry over to fiber bundles. A GRAPH of such a function sits in $B \times F$ as $(b, f(b))$. A graph always projects ONTO the base B and is ONE-TO-ONE.

A fiber bundle E is a TOTAL SPACE and, like $B \times F$, it has a projection $\pi : E \to B$. The PREIMAGE, $\pi^{-1}(b)$, of any point b is isomorphic to F. Unlike $B \times F$, there is no canonical projection from E to F. Instead, maps to F only make sense locally on B. Near any point b in the base B, there is a TRIVIALIZATION of E in which there are actual functions from a neighborhood to F.

These local functions can sometimes be patched together to give a (GLOBAL) SECTION $s : B \to E$ such that the projection of s is the identity. This is analogous to the map from a domain X of a function $f : X \to Y$ to its graph in $X \times Y$ by $\tilde{f}(x) = (x, f(x))$.

A fiber bundle also comes with a GROUP ACTION on the fiber. This group action represents the different ways the fiber can be viewed as equivalent. For instance, in topology, the GROUP might be the group of HOMEOMORPHISMS of the fiber. The group on a vector bundle is the group of INVERTIBLE LINEAR MAPS, which reflects the equivalent descriptions of a VECTOR SPACE using different BASES.

Fiber bundles are not always used to generalize functions. Sometimes they are convenient descriptions of interesting manifolds. A common example in GEOMETRIC TOPOLOGY is a torus bundle on the circle.

Fiber Direct Sum

See also DIRECT SUM

Fiber Space

A fiber space, depending on context, means either a FIBER BUNDLE or a FIBRATION.

See also FIBER BUNDLE, FIBRATION

Fibonacci

FIBONACCI NUMBER, FIBONACCI POLYNOMIAL

Fibonacci Coefficient

The coefficient defined by

$$\begin{bmatrix} m \\ k \end{bmatrix}_F = \frac{F_m F_{m-1} \cdots F_{m-k+1}}{F_1 F_2 \cdots F_k},$$

where $\begin{bmatrix} m \\ 0 \end{bmatrix}_F = 1$ and F_n is a FIBONACCI NUMBER. This coefficient satisfies

$$2\begin{bmatrix} n \\ m \end{bmatrix}_F = L_n \begin{bmatrix} m-1 \\ n \end{bmatrix} + L_{m-n} \begin{bmatrix} m-1 \\ n-1 \end{bmatrix}_F,$$

where L_n is a LUCAS NUMBER.

See also FIBONACCI NUMBER, LUCAS NUMBER

Fibonacci Dual Theorem

Let F_n be the nth FIBONACCI NUMBER. Then the sequence $\{F_n\}_{n=2}^{\infty} = \{1, 2, 3, 5, 8, \ldots\}$ is COMPLETE, even if one is restricted to subsequences in which no two consecutive terms are both passed over (until the desired total is reached; Brown 1965, Honsberger 1985).

See also COMPLETE SEQUENCE, FIBONACCI NUMBER.

Fibonacci Hyperbolic Functions

Let

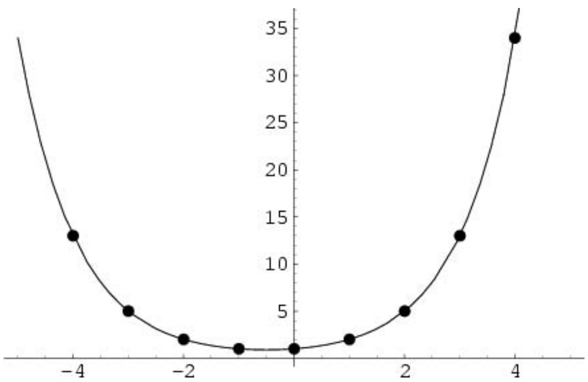
$$\psi \equiv 1 + \phi = \frac{1}{2}(3 + \sqrt{5}) \approx 2.618034 \tag{1}$$

where ϕ is the GOLDEN RATIO, and

$$\alpha = \ln \phi \approx 0.4812118. \tag{2}$$

Define the Fibonacci hyperbolic sine by

$$\mathrm{sFh}(x) \equiv \frac{\psi^x - \psi^{-x}}{\sqrt{5}} \tag{3}$$



$$= \frac{\phi^{2x} - \phi^{-2x}}{\sqrt{5}} \tag{4}$$

$$= \frac{2}{\sqrt{5}} \sinh[2x\alpha]. \tag{5}$$

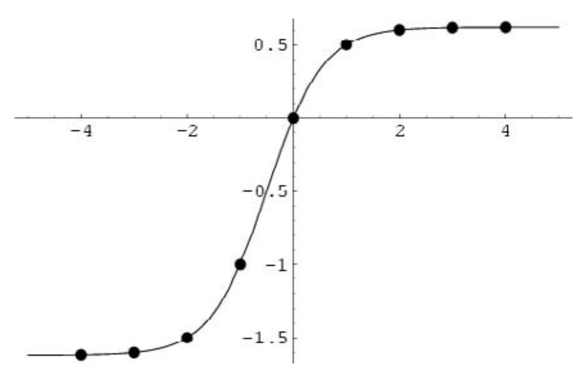
The function satisfies

$$\mathrm{sFh}(-x) = -\mathrm{sFh}(x), \tag{6}$$

and for $n \in \mathbb{Z}$, $\mathrm{sFh}(n) = F_{2n}$ where F_n is a FIBONACCI NUMBER.

Define the Fibonacci hyperbolic cosine by

$$\mathrm{cFh}(x) \equiv \frac{\psi^{x+1/2} + \psi^{-(x+1/2)}}{\sqrt{5}} \tag{7}$$



$$= \frac{\phi^{(2x+1)} + \phi^{-(2x+1)}}{\sqrt{5}} \tag{8}$$

$$= \frac{2}{\sqrt{5}} \cosh[(2x+1)\alpha). \tag{9}$$

This function satisfies

$$\mathrm{cFh}(-x) = \mathrm{cFh}(x-1), \tag{10}$$

and for $n \in \mathbb{Z}$, $\mathrm{cFh}(n) = F_{2n+1}$ where F_n is a FIBONACCI NUMBER.

Similarly, the Fibonacci hyperbolic tangent is defined

by

$$\mathrm{sFh}(x) \equiv \frac{\mathrm{cFh}(x)}{\mathrm{cFh}(x)},$$

and for $x \in \mathbb{Z}$, $\mathrm{cFh}(n) = F_{2n}/F_{2n+1}$.

Fibonacci Identity

Since

$$|(a+ib)(c+id)| = |a+ib||c+di| \quad (1)$$

$$|(ac-bd)+i(bc+ad)| = \sqrt{a^2+b^2}\sqrt{c^2+d^2}, \quad (2)$$

it follows that

$$(a^2+b^2)(c^2+d^2) = (ac-bd)^2 + (bc+ad)^2 \equiv e^2+f^2. \quad (3)$$

This identity implies the 2-dimensional CAUCHY'S INEQUALITY.

See also CAUCHY'S INEQUALITY, EULER FOUR-SQUARE IDENTITY, LEBESGUE IDENTITY

References

Petkovsek, M.; Wilf, H. S.; and Zeilberger, D. *A = B.* Wellesley, MA: A. K. Peters, p. 9, 1996.

Fibonacci Matrix

A SQUARE MATRIX related to the FIBONACCI NUMBERS. The simplest is the FIBONACCI Q-MATRIX.

Fibonacci n-Step Number

An n-step Fibonacci sequence is given by defining $F_k = 0$ for $k \le 0$, $F_1 = F_2 = 1$, $F_3 = 2$, and

$$F_k = \sum_{i=1}^{k} F_{n-i} \quad (1)$$

for $k > 3$. The case $n = 1$ corresponds to the degenerate 1, 1, 2, 2, 2, 2 ..., $n = 2$ to the usual FIBONACCI NUMBERS 1, 1, 2, 3, 5, 8, ... (Sloane's A000045), $n = 3$ to the TRIBONACCI NUMBERS 1, 1, 2, 4, 7, 13, 24, 44, 81, ... (Sloane's A000073), $n = 4$ to the TETRANACCI NUMBERS 1, 1, 2, 4, 8, 15, 29, 56, 108, ... (Sloane's A000078), etc.

The limit $\lim_{k\to\infty} F_k/F_{k-1}$ is given by solving

$$x^n(2-x) = 1, \quad (2)$$

or equivalently

$$x^n - x^{n-1} - x^{n-2} - \cdots - x - 1 = 0, \quad (3)$$

for x and then taking the REAL ROOT $x > 1$. For EVEN n, there are exactly two real roots, one greater than 1 and one less than 1, and for ODD n, there is exactly one real root, which is always ≥ 1.

If $n = 2$, equation (2) reduces to

$$x^2(2-x) = 1 \quad (4)$$

$$x^3 - 2x^2 + 1 = (x-1)(x^2-x-1) = 0, \quad (5)$$

giving solutions

$$x = 1, \frac{1}{2}\left(1 \pm \sqrt{5}\right). \quad (6)$$

The ratio is therefore

$$x = \frac{1}{2}\left(1+\sqrt{5}\right) = \phi = 1.618..., \quad (7)$$

which is the GOLDEN RATIO, as expected.

The analytic solutions for $n = 1$, 2, ... are given by

$$x_1 = 1$$

$$x_2 = \frac{1}{2}\left(1+\sqrt{5}\right)$$

$$x_3 = \frac{1}{3}\left[1 + \left(19 - 3\sqrt{33}\right)^{1/3} + \left(19 + 3\sqrt{33}\right)^{1/3}\right]$$

and numerically by 1, 1.61803, 1.83929, 1.92756, 1.96595, ..., approaching 2 as $n \to \infty$.

See also FIBONACCI NUMBER, TRIBONACCI NUMBER

References

Sloane, N. J. A. Sequences A000045/M0692, A000073/M1074, and A000078/M1108 in "An On-Line Version of the Encyclopedia of Integer Sequences." http://www.research.att.com/~njas/sequences/eisonline.html.

Fibonacci Number

The sequence of numbers F_n defined by the U_n in the LUCAS SEQUENCE, which can be viewed as a particular case of the FIBONACCI POLYNOMIALS $F_n(x)$ with $F_n = F_n(1)$. They are companions to the LUCAS NUMBERS and satisfy the same RECURRENCE RELATION,

$$F_n \equiv F_{n-2} + F_{n-1} \quad (1)$$

for $n = 3$, 4, ..., with $F_1 = F_2 = 1$. The first few Fibonacci numbers are 1, 1, 2, 3, 5, 8, 13, 21, ... (Sloane's A000045). The Fibonacci numbers give the number of pairs of rabbits n months after a single pair begins breeding (and newly born bunnies are assumed to begin breeding when they are two months old), as first described by Leonardo of Pisa in his book *Liber Abaci*. Kepler also described the Fibonacci numbers (Kepler 1966; Wells 1986, pp. 61–2 and 65).

The ratios of successive Fibonacci numbers F_n/F_{n-1} approaches the GOLDEN RATIO ϕ as n approaches infinity, as first proved by Scottish mathematician Robert Simson in 1753 (Wells 1986, p. 62). The ratios of alternate Fibonacci numbers are given by the CONVERGENTS to ϕ^{-2}, where ϕ is the GOLDEN RATIO, and are said to measure the fraction of a turn between successive leaves on the stalk of a plant (PHYLLOTAXIS): 1/2 for elm and linden, 1/3 for beech and hazel, 2/5 for oak and apple, 3/8 for poplar and rose, 5/13 for willow and almond, etc. (Coxeter 1969, Ball and Coxeter 1987). The Fibonacci numbers are sometimes called PINE CONE NUMBERS (Pappas 1989, p. 224). The role of the Fibonacci numbers in botany is sometimes called LUDWIG'S LAW (Szymkiewicz 1928; Wells 1986, p. 66; Steinhaus 1983, p. 299).

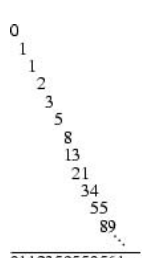
Another RECURRENCE RELATION for the Fibonacci numbers is

$$F_{n+1} = \left\lfloor \frac{F_n(1+\sqrt{5})+1}{2} \right\rfloor = \left\lfloor \phi F_n + \frac{1}{2} \right\rfloor, \tag{2}$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and ϕ is the GOLDEN RATIO. This expression follows from the more general RECURRENCE RELATION that

$$\begin{vmatrix} F_{n+1} & F_{n+2} & \cdots & F_{n+k} \\ F_{n+k+1} & F_{n+k+2} & \cdots & F_{n+2k} \\ \vdots & \vdots & \ddots & \vdots \\ F_{n+k(k-1)+1} & F_{n+k(k-1)+2} & \cdots & F_{n+k^2} \end{vmatrix} = 0. \tag{3}$$

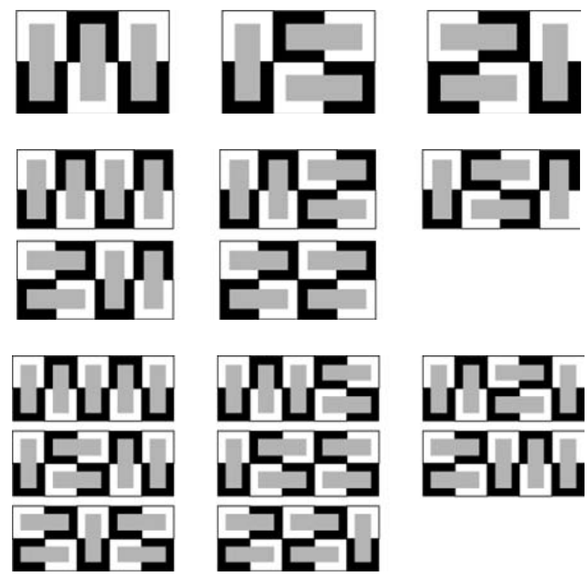
The GENERATING FUNCTION for the Fibonacci numbers is



$$g(x) = \sum_{n=0}^{\infty} F_n x^n = \frac{x}{1-x-x^2}$$
$$= x + x^2 + 2x^3 + 3x^4 + 5x^5 + \ldots. \tag{4}$$

By plugging in $x = 1/10$, this gives the curious addition tree illustrated below,

$$\sum_{n=0}^{\infty} \frac{F_n}{10^n} = \frac{10}{89}, \tag{5}$$



so

$$\sum_{n=0}^{\infty} \frac{F_n}{10^{n+1}} = \frac{1}{89} \tag{6}$$

Yuri Matiyasevich (1970) showed that there is a polynomial P in n, m, and a number of other variables x, y, z, ... having the property that $n = F_{2m}$ IFF there exist integers x, y, z, ... such that $p(n, m, x, y, z, \ldots) = 0$. This led to the proof of the impossibility of the tenth of HILBERT'S PROBLEMS (does there exist a general method for solving DIOPHANTINE EQUATIONS?) by Julia Robinson and Martin Davis in 1970 (Reid 1997, p. 107).

The Fibonacci number F_{n+1} gives the number of ways for 2×1 DOMINOES to cover a $2 \times n$ CHECKERBOARD, as illustrated in the following diagrams (Dickau).

The number of ways of picking a SET (including the EMPTY SET) from the numbers 1, 2, ..., n without picking two consecutive numbers is F_{n+2}. The number of ways of picking a set (including the EMPTY SET) from the numbers 1, 2, ..., n without picking two consecutive numbers (where 1 and n are now consecutive) is $L_n = F_{n+1} + F_{n-1}$, where L_n is a LUCAS NUMBER. The probability of not getting two heads in a row in n tosses of a COIN is $F_{n+2}/2^n$ (Honsberger 1985, pp. 120–22). Fibonacci numbers are also related to the number of ways in which n COIN TOSSES can be made such that there are not three consecutive heads or tails. The number of ideals of an n-element FENCE POSET is the Fibonacci number F_n.

Given a RESISTOR NETWORK of n 1-Ω resistors, each incrementally connected in series or parallel to the preceding resistors, then the net resistance is a RATIONAL NUMBER having maximum possible denominator of F_{n+1}.

The Fibonacci numbers are given in terms of the CHEBYSHEV POLYNOMIAL OF THE SECOND KIND by

$$F_n = i^{n-1} U_{n-1}\left(-\frac{1}{2} i\right). \tag{7}$$

Sum identities include

$$\sum_{k=1}^{n} F_k = F_{n+2} - 1. \tag{8}$$

$$F_1 + F_3 + F_5 + \ldots + F_{2k+1} = F_{2k+2} \tag{9}$$

$$1 + F_2 + F_4 + F_6 + \ldots + F_{2k} = F_{2k+1} \tag{10}$$

$$\sum_{k=1}^{n} F_k^2 = F_n F_{n+1} \tag{11}$$

$$F_{2n} = F_{n+1}^2 - F_{n-1}^2 \tag{12}$$

$$F_{3n} = F_{n+1}^3 + F_n^3 + F_{n-1}^3. \tag{13}$$

There are a number of particular pretty algebraic identities involving the Fibonacci numbers, including

$$F_{n+1}^2 = 4F_n F_{n-1} + F_{n-2}^2 \tag{14}$$

(Brousseau 1972), CATALAN'S IDENTITY

$$F_n^2 - F_{n+r}F_{n-r} = (-1)^{n-r} F_r^2, \tag{15}$$

D'OCAGNE'S IDENTITY

$$F_m F_{n+1} - F_n F_{m+1} = (-1)^n F_{m-n}, \tag{16}$$

and the GELIN-CESÀRO IDENTITY

$$F_n^4 - F_{n-2}F_{n-1}F_{n+1}F_{n+2} = 1. \tag{17}$$

Letting $r = 1$ in (15) gives CASSINI'S IDENTITY

$$F_{n-1}F_{n+1} - F_n^2 = (-1)^n, \tag{18}$$

sometimes also called Simson's formula since it was also discovered by Simson (Coxeter and Greitzer 1967, p. 41; Coxeter 1969, pp. 165–68; Petkovsek *et al.* 1996, p. 12).

The Fibonacci numbers obey the negation formula

$$F_{-n} = (-1)^{n+1} F_n, \tag{19}$$

the addition formula

$$F_{m+n} = \frac{1}{2}(F_m L_n + L_m F_n), \tag{20}$$

where L_n is a LUCAS NUMBER, the subtraction formula

$$F_{m-n} = \frac{1}{2}(-1)(F_m L_n - L_m F_n), \tag{21}$$

the fundamental identity

$$L_n^2 - 5F_n^2 = 4(-1)^n \tag{22}$$

conjugation relation

$$F_n - \frac{1}{5}(L_{n-1} + L_{n+1}), \tag{23}$$

successor relation

$$F_{n+1} = \frac{1}{2}(F_n + L_n), \tag{24}$$

double-angle formula

$$F_{2n} = F_n L_n, \tag{25}$$

multiple-angle recurrence

$$F_{kn} = L_k F_{k(n-1)} - (-1)^k F_{k(n-2)}, \tag{26}$$

multiple-angle formulas

$$F_{kn} = \frac{1}{2^{k-1}} \sum_{i=0}^{\lfloor (k-1)/2 \rfloor} \binom{k}{2i+1} 5^i F_n^{2i+1} L_n^{k-1-2i} \tag{27}$$

$$= F_n \sum_{i=0}^{\lfloor (k-1)/2 \rfloor} \binom{k-1-i}{i} (-1)^{i(n+1)} L_n^{k-1-2i} \tag{28}$$

$$= \begin{cases} L_n \sum_{i=0}^{(k-2)/2} \binom{k-1-i}{i} (-1)^{in} 5^{k/2-1-i} F_n^{k-1-2i} & \text{for } k \text{ even} \\ \sum_{i=0}^{\lfloor k/2 \rfloor} \frac{k}{k-i} \binom{k-i}{i} (-1)^{in} 5^{\lfloor k/2 \rfloor - i} F_n^{k-2i} & \text{for } k \text{ odd} \end{cases} \tag{29}$$

$$= \sum_{i=0}^{k} \binom{k}{i} F_i F_n^i F_{n-1}^{k-i}, \tag{30}$$

product expansions

$$F_m F_n = \frac{1}{5}[L_{m+n} - (-1)^n L_{m-n}] \tag{31}$$

and

$$F_m L_n = F_{m+n} + (-1)^n F_{m-n}, \tag{32}$$

square expansion,

$$F_n^2 = \frac{1}{5}[L_{2n} - 2(-1)^n], \tag{33}$$

and power expansion

$$F_n^k = \frac{1}{2.5^{\lfloor k/2 \rfloor}} \sum_{i=0}^{k} \binom{k}{i} (-1)^{i(n+1)} \times \begin{cases} F_{(k-2i)n} & \text{for } k \text{ odd} \\ L_{(k-2i)n} & \text{for } k \text{ even}. \end{cases} \tag{34}$$

Honsberger (1985, p. 107) gives the general relations

$$F_{n+m} = F_{n-1}F_m + F_n F_{m+1} \tag{35}$$

$$F_{(k+1)n} = F_{n-1}F_{kn} + F_n F_{kn+1} \tag{36}$$

$$F_n = F_l F_{n-l+1} + F_{l-1}F_{n-l}. \tag{37}$$

In the case $l = n - l + 1$, then $l = (n+1)/2$ and for n ODD,

$$F_n = F_{(n+1)/2}^2 + F_{(n-1)/2}^2. \tag{38}$$

Similarly, for n EVEN,

$$F_n = F_{n/2+1}^2 - F_{n/2-1}^2. \quad (39)$$

Letting $k \equiv (n-1)/2$ gives the identities

$$F_{2k+1} = F_{k+1}^2 + F_k^2 \quad (40)$$

$$F_{n+2}^2 - F_{n+1}^2 = F_n F_{n+3} \quad (41)$$

$$F_n^2 = F_{n-1}^2 + 3F_{n-2}^2 + 2F_{n-2}F_{n-3}. \quad (42)$$

Sum FORMULAS for F_n include

$$F_n = \frac{1}{2^{n-1}}\left[\binom{n}{1} + 5\binom{n}{3} + 5^2\binom{n}{5} + \ldots\right] \quad (43)$$

$$F_{n+1} = \binom{n}{0} + \binom{n-1}{1} + \binom{n-2}{2} + \ldots \quad (44)$$

(Wells 1986, p. 63). Additional identities can be found throughout the *Fibonacci Quarterly* journal. A list of 47 generalized identities are given by Halton (1965).

In terms of the LUCAS NUMBER L_n,

$$F_{2n} = F_n L_n \quad (45)$$

$$F_{2n}(L_{2n}^2 - 1) = F_{6n} \quad (46)$$

$$F_{m+p} + (-1)^{p+1} F_{m-p} = F_p L_m \quad (47)$$

$$\sum_{k=a+1}^{a+4n} F_k = F_{a+4n+2} - F_{a+2} = F_{2n} L_{a+2n+2} \quad (48)$$

(Honsberger 1985, pp. 111–13). A remarkable identity is

$$\exp\left(L_{1x} + \frac{1}{2}L_2 x^2 + \frac{1}{3}L_3 x^3 + \ldots\right)$$
$$= F_1 + F_2 x + F_3 x^3 + \ldots \quad (49)$$

(Honsberger 1985, pp. 118–19). It is also true that

$$\frac{L_n^2 - (-1)^a L_{n+a}^2}{F_n^2 - (-1)^a F_{n+a}^2} = 5 \quad (50)$$

for a ODD, and

$$\frac{L_n^2 + L_{n+a}^2 - 8(-1)^n}{F_n^2 + F_{n+a}^2} = 5 \quad (51)$$

for a EVEN (Freitag 1996).

The equation (1) is a LINEAR RECURRENCE SEQUENCE

$$x_n = Ax_{x-1} + Bx_{n-2} \quad n \geq 3, \quad (52)$$

so the closed form for F_n is given by

$$F_n = \frac{\alpha^n - \beta^n}{\alpha - \beta}, \quad (53)$$

where α and β are the roots of $x^2 = Ax + B$. Here, $A = B = 1$, so the equation becomes

$$x^2 - x - 1 = 0, \quad (54)$$

which has ROOTS

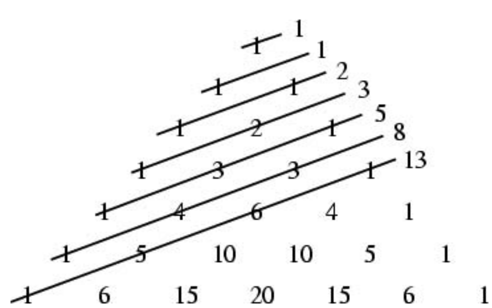
$$x = \frac{1}{2}\left(1 \pm \sqrt{5}\right). \quad (55)$$

The closed form is therefore given by

$$F_n = \frac{(1+\sqrt{5})^n - (1-\sqrt{5})^n}{2^n\sqrt{5}}, \quad (56)$$

This is known as BINET'S FIBONACCI NUMBER FORMULA (Wells 1986, p. 62). Another closed form is

$$F_n = \left[\frac{1}{\sqrt{5}}\left(\frac{1+\sqrt{5}}{2}\right)^n\right] = \left[\frac{\phi^n}{\sqrt{5}}\right], \quad (57)$$



where $[x]$ is the NINT function (Wells 1986, p. 62).

From (1), the RATIO of consecutive terms is

$$\frac{F_n}{F_{n-1}} = 1 + \frac{F_{n-2}}{F_{n-1}} = 1 + \cfrac{1}{\cfrac{F_{n-1}}{F_{n-2}}}$$
$$= 1 + \cfrac{1}{1 + \cfrac{1}{\cfrac{F_{n-3}}{F_{n-2}}}} = \left[1, 1, \ldots, \frac{F_2}{F_1}\right]$$
$$= \underbrace{[1, 1, \ldots, 1]}_{n-1}, \quad (58)$$

which is just the first few terms of the CONTINUED FRACTION for the GOLDEN RATIO ϕ. Therefore,

$$\lim_{n\to\infty} \frac{F_n}{F_{n-1}} = \phi. \quad (59)$$

The "SHALLOW DIAGONALS" of PASCAL'S TRIANGLE sum to Fibonacci numbers (Pappas 1989),

$$\sum_{k=1}^{n} \binom{k}{n-k}$$
$$= \frac{(-1)^n\, {}_3F_2\left(1, 2, 1-n; \frac{1}{2}(3-n), 2-\frac{1}{2}n; -\frac{1}{4}\right)}{\pi(2 - 3n + n^2)}$$
$$= F_{n+1,} \quad (60)$$

where ${}_3F_2(a, b, c; d, e; z)$ is a GENERALIZED HYPERGEOMETRIC FUNCTION.

Guy (1990) notes the curious fact that $\lceil e^{(n-1)/2} \rceil$ for $n = 0, 1, \ldots$ gives 1, 1, 2, 5, 8, 13, 21, 34, 55, ..., but then continues 91, 149, ... (Sloane's A005181). Taking the product of the first n Fibonacci numbers and adding 1 for $n = 1, 2, \ldots$ gives the sequence 2, 2, 3, 77, 31, 241, ... (Sloane's A052449). If these, 2, 2, 3, 7, 31, 241, 3121, ... (Sloane's A053413) are prime, i.e., the terms 1, 2, 3, 4, 5, 6, 7, 8, 22, 28, ... (Sloane's A053408).

The sequence of final digits in Fibonacci numbers repeats in cycles of 60. The last two digits repeat in 300, the last three in 1500, the last four in 15,000, etc. The number of Fibonacci numbers between n and $2n$ is either 1 or 2 (Wells 1986, p. 65).

Cesàro derived the finite sums

$$\sum_{k=0}^{n} \binom{n}{k} F_k = F_{2n} \tag{61}$$

$$\sum_{k=0}^{n} \binom{n}{k} 2^k F_k = F_{3n} \tag{62}$$

(Honsberger 1985, pp. 109–10). The Fibonacci numbers satisfy the power recurrence

$$\sum_{j=0}^{t+1} (-1)^{j(j+1)/2} \begin{bmatrix} t+1 \\ j \end{bmatrix}_F F_{n-j}^t = 0, \tag{63}$$

where $\begin{bmatrix} a \\ b \end{bmatrix}_F$ is a FIBONACCI COEFFICIENT, the reciprocal sum

$$\sum_{k=1}^{n} \frac{(-1)^k}{F_k F_{k+a}} = \frac{F_n}{F_a} \sum_{k=1}^{a} \frac{(-1)^k}{F_k F_{k+n}}, \tag{64}$$

the convolution

$$\sum_{k=0}^{n} F_k F_{n-k} = \frac{1}{5}(nL_n - F_n), \tag{65}$$

the partial fraction decomposition

$$\frac{1}{F_{n+a} F_{n+b} F_{n+c}} = \frac{A}{F_{n+a}} + \frac{B}{F_{n+b}} + \frac{C}{F_{n+c}}, \tag{66}$$

where

$$A = \frac{(-1)^{n-a}}{F_{b-a} F_{c-a}} \tag{67}$$

$$B = \frac{(-1)^{n-b}}{F_{c-b} F_{a-b}} \tag{68}$$

$$C = \frac{(-1)^{n-c}}{F_{a-c} F_{b-c}}, \tag{69}$$

and the summation formula

$$\sum_{k=0}^{n} x^k F_{ak+b} = \frac{g(n+1) - g(0)}{1 - L_a x + (-1)^a x^2}, \tag{70}$$

where

$$g(n) = (-1)^a F_{a(n-1)+b} x^{n+1} - F_{an+b} x^n. \tag{71}$$

Infinite sums include

$$\sum_{n=1}^{\infty} \frac{(-1)^n}{F_n F_{n+2}} = 2 - \sqrt{5} \tag{72}$$

(Clark 1995) and

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{F_{n+1} F_{n+2}} = \phi^{-2} \tag{73}$$

$$\sum_{n=1}^{\infty} 1 over F_{2n} F_{2n+2} = \phi^{-2} \tag{74}$$

where ϕ is the GOLDEN RATIO (Wells 1986, p. 65).

For $n \geq 3$, $F_n | F_m$ IFF $n | m$ (Wells 1986, p. 65). $L_n | L_m$ IFF n divides into m an EVEN number of times. $(F_m, F_n) = F_{(m,n)}$ (Michael 1964; Honsberger 1985, pp. 131–32). No ODD Fibonacci number is divisible by 17 (Honsberger 1985, pp. 132 and 242). No Fibonacci number > 8 is ever OF THE FORM $p - 1$ or $p + 1$ where p is a PRIME NUMBER (Honsberger 1985, p. 133).

Consider the sum

$$sk = \sum_{n=2}^{k} \frac{1}{F_{n-1} F_{n+1}} = \sum_{n=2}^{k} \left(\frac{1}{F_{n-1} F_n} - \frac{1}{F_n F_{n+1}} \right). \tag{75}$$

This is a TELESCOPING SUM, so

$$s_k = 1 - \frac{1}{F_{k+1} F_{k+2}}, \tag{76}$$

thus

$$S \equiv \lim_{k \to \infty} s_k = 1 \tag{77}$$

(Honsberger 1985, pp. 134–35). Using BINET'S FIBONACCI NUMBER FORMULA, it also follows that

$$\frac{F_{n+r}}{F_n} = \frac{\alpha^{n+r} - \beta^{n+r}}{\alpha^n - \beta^n} = \frac{\alpha^{n+r}}{\alpha^n} \frac{1 - \left(\frac{\beta}{\alpha}\right)^{n+r}}{1 - \left(\frac{\beta}{\alpha}\right)^n}, \tag{78}$$

where

$$\alpha = \frac{1}{2}\left(1 + \sqrt{5}\right) \tag{79}$$

$$\beta = \frac{1}{2}\left(1 - \sqrt{5}\right) \tag{80}$$

so

$$\lim_{n\to\infty} \frac{F_{n+r}}{F_n} = \alpha^r. \quad (81)$$

$$S' = \sum_{n=1}^{\infty} \frac{F_n}{F_{n+1}F_{n+2}} = 1 \quad (82)$$

(Honsberger 1985, pp. 138 and 242–43). The MILLIN SERIES has sum

$$S'' \equiv \sum_{n=0}^{\infty} \frac{1}{F_{2^n}} = \frac{1}{2}\left(7-\sqrt{5}\right) \quad (83)$$

(Honsberger 1985, pp. 135–37).

The Fibonacci numbers are COMPLETE. In fact, dropping one number still leaves a COMPLETE SEQUENCE, although dropping two numbers does not (Honsberger 1985, pp. 123 and 126). Dropping two terms from the Fibonacci numbers produces a sequence which is not even WEAKLY COMPLETE (Honsberger 1985, p. 128). However, the sequence

$$F'_n \equiv F_n - (-1)^n \quad (84)$$

is WEAKLY COMPLETE, even with any finite subsequence deleted (Graham 1964). $\{F_n^2\}$ is not COMPLETE, but $\{F_n^2\}+\{F_n^2\}$ are. 2^{N-1} copies of $\{F_n^N\}$ are COMPLETE.

For a discussion of SQUARE Fibonacci numbers, see Cohn (1964), who proved that the only SQUARE NUMBER Fibonacci numbers are 1 and $F_{12}=144$ (Cohn 1964, Guy 1994). Ming (1989) proved that the only TRIANGULAR Fibonacci numbers are 1, 3, 21, and 55. The Fibonacci and LUCAS NUMBERS have no common terms except 1 and 3. The only CUBIC Fibonacci numbers are 1 and 8.

$$\left(F_nF_{n+3}, 2F_{n+1}F_{n+2}, F_{2n+3} = F_{n+1}^2 + F_{n+2}^2\right) \quad (85)$$

is a PYTHAGOREAN TRIPLE.

$$F_{4n}^2 + 8F_{2n}(F_{2n}+F_{6n}) = (3F_{4n})^2 \quad (86)$$

is always a SQUARE NUMBER (Honsberger 1985, p. 243).

In 1975, James P. Jones showed that the Fibonacci numbers are the POSITIVE INTEGER values of the POLYNOMIAL

$$P(x,y) = -y^5 + 2y^4x + y^3x^2 - 2y^2x^3 - y\left(x^4-2\right) \quad (87)$$

for GAUSSIAN INTEGERS x and y (Le Lionnais 1983). If n and k are two POSITIVE INTEGERS, then between n^k and n^{k+1}, there can never occur more than n Fibonacci numbers (Honsberger 1985, pp. 104–05).

Every F_n that is PRIME has a PRIME index n, with the exception of $F_4=3$. However, the converse is not true (i.e., not every prime index p gives a PRIME F_p). The first few PRIME Fibonacci numbers F_n are 2, 3, 5, 13, 89, 233, 1597, 28657, 514229, ... (Sloane's A005478), which occur for n = 3, 4, 5, 7, 11, 13, 17, 23, 29, 43, 47, 83, 131, 137, 359, 431, 433, 449, 509, 569, 571, ... (Sloane's A001605; Dubner and Keller 1999). Gardner's statement that F_{531} is prime is incorrect, especially since 531 is not even PRIME (Gardner 1979, p. 161). It is not known if there are an INFINITE number of Fibonacci primes.

The Fibonacci numbers F_n, are SQUAREFUL for n = 6, 12, 18, 24, 25, 30, 36, 42, 48, 50, 54, 56, 60, 66, ..., 372, 375, 378, 384, ... (Sloane's A037917) and SQUAREFREE for n = 1, 2, 3, 4, 5, 7, 8, 9, 10, 11, 13, ... (Sloane's A037918). $4|F_{6n}$ and $25|F_{25n}$ for all n, and there is at least one $n \le 2m$ such that $m|F_n$. No SQUAREFUL Fibonacci numbers F_p are known with p PRIME.

Fibonacci Polynomial

The W POLYNOMIALS obtained by setting $p(x)=x$ and $q(x)=1$ in the LUCAS POLYNOMIAL SEQUENCE. (The corresponding w POLYNOMIALS are called LUCAS POLYNOMIALS.) The Fibonacci polynomials are defined by the RECURRENCE RELATION

$$F_{n+1}(x)=xF_n(x)+F_{n-1}(x), \tag{1}$$

with $F_1(x)=1$ and $F_2(x)=x$. They are also given by

the explicit sum formula

$$F_n(x) = \sum_{j=0}^{\lfloor (n-1)/2 \rfloor} \binom{n-j-1}{j} x^{n-2j-1}, \quad (2)$$

where $\lfloor x \rfloor$ is the FLOOR FUNCTION and $\binom{n}{m}$ is a BINOMIAL COEFFICIENT. The first few Fibonacci polynomials are

$$F_1(x) = 1$$

$$F_2(x) = x$$

$$F_3(x) = x^2 + 1$$

$$F_4(x) = x^3 + 2x$$

$$F_5(x) = x^4 + 3x^2 + 1.$$

The Fibonacci polynomials are normalized so that

$$F_n(1) = F_n, \quad (3)$$

where the F_ns are FIBONACCI NUMBERS.
The Fibonacci polynomials are related to the MORGAN-VOYCE POLYNOMIALS by

$$F_{2n+1}(x) = b_n(x^2) \quad (4)$$

$$F_{2n+n2}(x) = xB_n(x^2) \quad (5)$$

(Swamy 1968).

Fibonacci Pseudoprime

Consider a LUCAS SEQUENCE with $P > 0$ and $Q = \pm 1$. A Fibonacci pseudoprime is a COMPOSITE NUMBER n such that

$$V_n \equiv P \text{ (mod n)}.$$

There exist no EVEN Fibonacci pseudoprimes with parameters $P = 1$ and $Q = -1$ (Di Porto 1993) or $P = Q = 1$ (André-Jeannin 1996). André-Jeannin (1996) also proved that if $(P, Q) \neq (1, -1)$ and $(P, Q) \neq (1, 1)$, then there exists at least one EVEN Fibonacci pseudoprime with parameters P and Q.

Fibonacci Q-Matrix

A FIBONACCI MATRIX OF THE FORM

$$M = \begin{bmatrix} m & 1 \\ 1 & 0 \end{bmatrix}. \quad (1)$$

If U and V are defined as BINET FORMS

$$U_n = mU_{n-1} + U_{n-2} \ (\mathrm{U}_0 = 0, \mathrm{U}_1 = 1) \quad (2)$$

$$V_n = mV_{n-1} + V_{n-2} \ (\mathrm{V}_0 = 2, \mathrm{V}_1 = \mathrm{m}), \quad (3)$$

then

$$M = \begin{bmatrix} U_{n+1} & U_n \\ U_n & U_{n-1} \end{bmatrix} \quad (4)$$

$$M^{-1} = M - mI = \begin{bmatrix} 0 & 1 \\ 1 & -m \end{bmatrix}. \quad (5)$$

Defining

$$Q \equiv \begin{bmatrix} F_2 & F_1 \\ F_1 & F_0 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}, \quad (6)$$

then

$$Q^n = \begin{bmatrix} F_{n+1} & F_n \\ F_n & F_{n-1} \end{bmatrix} \quad (7)$$

(Honsberger 1985, pp. 106–07).

FIBONACCI NUMBER

Fibration

If $f : E \to B$ is a FIBER BUNDLE with B a PARACOMPACT TOPOLOGICAL SPACE, then f satisfies the HOMOTOPY LIFTING PROPERTY with respect to all TOPOLOGICAL SPACES. In other words, if $g : [0, 1] \times X \to B$ is a HOMOTOPY from g_0 to g_1, and if g_0' is a LIFT of the MAP g_0 with respect to f, then g has a LIFT to a MAP g' with respect to f. Therefore, if you have a HOMOTOPY of a MAP into B, and if the beginning of it has a LIFT, then that LIFT can be extended to a LIFT of the HOMOTOPY itself.

A fibration is a MAP between TOPOLOGICAL SPACES $f : E \to B$ such that it satisfies the HOMOTOPY LIFTING PROPERTY.

Field

A field is any set of elements which satisfies the FIELD AXIOMS for both addition and multiplication and is a commutative DIVISION ALGEBRA. An archaic name for a field is RATIONAL DOMAIN. The French term for a field is *corps* and the German word is *Körper*, both meaning "body." A field with a finite number of members is known as a FINITE FIELD or Galois field.

Because the identity condition must be different for addition and multiplication, every field must have at least two elements. Examples include the COMPLEX NUMBERS ($\mathbb{C}$), RATIONAL NUMBERS ($\mathbb{Q}$), and REAL NUMBERS ($\mathbb{R}$), but *not* the INTEGERS (F), which form only a RING. It has been proven by Hilbert and Weierstrass that all generalizations of the field concept to triplets of elements are equivalent to the field of COMPLEX NUMBERS.

Field Axioms

The field axioms are generally written in additive and multiplicative pairs.

Name	Addition	Multiplication
Commutativity	$a+b=b+a$	$ab = ba$
Associativity	$(a+b)+c=a+(b+c)$	$(ab)c=a(bc)$
Distributivity	$a(b+c)=ab+ac$	$(a+b)c=ac+bc$
Identity	$a+0=a=0+a$	$a\cdot 1=a=1\cdot a$
Inverses	$a+(-a)=0=(-a)+a$	$aa^{-1}=1=a^{-1}a$ if $a\neq 0$

Fields Medal

Portions of this entry contributed by MICHEL BARRAN

The mathematical equivalent of the Nobel Prize (there is no Nobel Prize in mathematics) which is awarded by the International Mathematical Union every four years to one or more outstanding researchers. "Fields Medals" are more properly known by their official name, "International medals for outstanding discoveries in mathematics."

The Field medals were first proposed at the 1924 International Congress of Mathematicians in Toronto, where a resolution was adopted stating that at each subsequent conference, two gold medals should be awarded to recognize outstanding mathematical achievement. Professor J. C. Fields, a Canadian mathematician who was secretary of the 1924 Congress, later donated funds establishing the medals which were named in his honor. Consistent with Fields' wish that the awards recognize both existing work and the promise of future achievement, it was agreed to restrict the medals to mathematicians not over forty at the year of the Congress. In 1966 it was agreed that, in light of the great expansion of mathematical research, up to four medals could be awarded at each Congress.

The Fields Medal is the highest scientific award for mathematicians, and is presented every four years at the International Congress of Mathematicians, to-

gether with a prize of 15,000 Canadian dollars. The first Fields Medal was awarded in 1936 at the World Congress in Oslo. The Fields Medal is made of gold, and shows the head of Archimedes (287–12 BC) together with a quotation attributed to him: "Transire suum pectus mundoque potiri" ("Rise above oneself and grasp the world"). The reverse side bears the inscription: "Congregati ex toto orbe mathematici ob scripta insignia tribuere" ("the mathematicians assembled here from all over the world pay tribute for outstanding work").

Nobel prizes were created in the will of the Swedish chemist and inventor of dynamite Alfred Nobel, but Nobel, who was an inventor and industrialist, did not create a prize in mathematics because he was not particularly interested in mathematics or theoretical science. In fact, his will speaks of prizes for those "inventions or discoveries" of greatest practical benefit to mankind. While it is commonly stated that Nobel decided against a Nobel prize in math because of anger over the romantic attentions of a famous mathematician (often claimed to be Gosta Mittag-Leffler) to a women in his life, there is no historical evidence to support the story. Furthermore, Nobel was a lifelong batchelor, although he did has a Viennese woman named Sophie Hess as his mistress (Lopez-Ortiz).

The following table summarizes Fields Medals winners together with their institutions.

year	winners
1936	Lars Valerian Ahlfors (Harvard University)
	Jesse Douglas (Massachusetts Institute of Technology)
1950	Laurent Schwartz (University of Nancy)
	Alte Selberg (Institute for Advanced Study, Princeton)
1954	Kunihiko Kodaira (Princeton University)
	Jean-Pierre Serre (University of Paris)
1958	Klaus Friedrich Roth (University of London)
	René Thom (University of Strasbourg)
1962	Lars V. Hörmander (University of Stockholm)
	John Willard Milnor (Princeton University)
1966	Michael Francis Atiyah (Oxford University)
	Paul Joseph Cohen (Stanford University)
	Alexander Grothendieck (University of Paris)
	Stephen Smale (University of California, Berkeley)
1970	Alan Baker (Cambridge University)
	Heisuke Hironaka (Harvard University)
	Serge P. Novikov (Moscow University)
	John Griggs Thompson (Cambridge University)
1974	Enrico Bombieri (University of Pisa)
	David Bryant Mumford (Harvard University)
1978	Pierre René Deligne (Institut des Hautes Études Scientifiques)
	Charles Louis Fefferman (Princeton University)
	Gregori Alexandrovitch Margulis (Moscow University)
	Daniel G. Quillen (Massachusetts Institute of Technology)
1982	Alain Connes (Institut des Hautes Études Scientifiques)
	William P. Thurston (Princeton University)
	Shing-Tung Yau (Institute for Advanced Study, Princeton)
1986	Simon Donaldson (Oxford University)
	Gerd Faltings (Princeton University)
	Michael Freedman (University of California, San Diego)
1990	Vladimir Drinfeld (Phys. Inst. Kharkov)
	Vaughan Jones (University of California, Berkeley)
	Shigefumi Mori (University of Kyoto?)
	Edward Witten (Institute for Advanced Study, Princeton)
1994	Pierre-Louis Lions (Université de Paris-Dauphine)
	Jean-Christophe Yoccoz (Université de Paris-Sud)
	Jean Bourgain (Institute for Advanced Study, Princeton)
	Efim Zelmanov (University of Wisconsin)
1998	Richard E. Borcherds (Cambridge University)
	W. Timothy Gowers (Cambridge University)
	Maxim Kontsevich (IHES Bures-sur-Yvette)
	Curtis T. McMullen (Harvard University)

Fifteen Theorem

A theorem due to Conway *et al.* (1997) which states that, if a positive definite QUADRATIC FORM with INTEGER MATRIX entries represents all natural numbers up to 15, then it represents all natural numbers. This theorem contains LAGRANGE'S FOUR-SQUARE THEOREM, since every number up to 15 is the sum of at most four SQUARES.

See also INTEGER MATRIX, INTEGER-MATRIX FORM, LAGRANGE'S FOUR-SQUARE THEOREM, QUADRATIC FORM

Figurate Number

A number which can be represented by a regular geometrical arrangement of equally spaced points. If the arrangement forms a REGULAR POLYGON, the number is called a POLYGONAL NUMBER. The polygonal numbers illustrated above are called triangular, square, pentagonal, and hexagon numbers, respectively. Figurate numbers can also form other shapes such as centered polygons, L-shapes, 3-dimensional solids, etc.

The nth regular r-polytopic number is given by

$$P_r(n) = \binom{n+r-1}{n} = \frac{1}{r!} n^{(r)},$$

where $\binom{n}{k}$ is a BINOMIAL COEFFICIENT and $n^{(k)}$ is a RISING FACTORIAL, so

$$P_2(n) = \frac{1}{2} n(n+1)$$

are the TRIANGULAR NUMBERS,

$$P_3(n) = \frac{1}{6} n(n+1)(n+2)$$

the TETRAHEDRAL NUMBERS,

$$P_4(n) = \frac{1}{24} n(n+1)(n+1)(n+3)$$

the PENTATOPE NUMBERS, and so on (Dickson 1952, p. 7).

The following table lists the most common types of figurate numbers.

Name	FORMULA
BIQUADRATIC NUMBER	n^4
CENTERED CUBE NUMBER	$(2n-1)(n^2-n+1)$
CENTERED PENTAGONAL NUMBER	$\frac{1}{2}(5n^2+5n+2)$
CENTERED SQUARE NUMBER	$n^2+(n-1)^2$
CENTERED TRIANGULAR NUMBER	$\frac{1}{2}(3n^2-3n+2)$
CUBIC NUMBER	n^3
DECAGONAL NUMBER	$4n^2-3n$
GNOMONIC NUMBER	$2n-1$
Hauy OCTAHEDRAL NUMBER	$\frac{1}{3}(2n-1)(2n^2-2n+3)$
Hauy RHOMBIC DODECAHEDRAL NUMBER	$(2n-1)(8n^2-14n+7)$
HEPTAGONAL NUMBER	$\frac{1}{2}n(5n-3)$
HEX NUMBER	$3n^2-3n+1$
HEPTAGONAL PYRAMIDAL NUMBER	$\frac{1}{6}n(n+1)(5n-2)$
HEXAGONAL NUMBER	$n(2n-1)$
HEXAGONAL PYRAMIDAL NUMBER	$\frac{1}{6}n(n+1)(4n-1)$

OCTAGONAL NUMBER	$n(3n-2)$
OCTAHEDRAL NUMBER	$\frac{1}{3}n(2n^2+1)$
PENTAGONAL NUMBER	$\frac{1}{2}n(3n-1)$
PENTAGONAL PYRAMIDAL NUMBER	$\frac{1}{2}n^2(n+1)$
PENTATOPE NUMBER	$\frac{1}{24}n(n+1)(n+2)(n+3)$
PRONIC NUMBER	$n(n+1)$
RHOMBIC DODECAHEDRAL NUMBER	$(2n-1)(2n^2-2n+1)$
SQUARE NUMBER	n^2
SQUARE PYRAMIDAL NUMBER	$\frac{1}{6}n(n+1)(2n+1)$
STELLA OCTANGULA NUMBER	$n(2n^2-1)$
TETRAHEDRAL NUMBER	$\frac{1}{6}n(n+1)(n+2)$
TRIANGULAR NUMBER	$\frac{1}{2}n(n+1)$
TRUNCATED OCTAHEDRAL NUMBER	$16n^3-33n^2+24n-6$
TRUNCATED TETRAHEDRAL NUMBER	$\frac{1}{6}n(23n^2-27n+10)$

Figurate Number Triangle

A PASCAL'S TRIANGLE written in a square grid and padded with zeroes, as written by Jakob Bernoulli (Smith 1984). The figurate number triangle therefore has entries

$$a_{ij} = \binom{i}{j},$$

where i is the row number, j the column number, and $\binom{i}{j}$ a BINOMIAL COEFFICIENT. Written out explicitly (beginning each row with $j = 0$),

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 1 & 1 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 1 & 2 & 1 & 0 & 0 & 0 & 0 & \cdots \\ 1 & 3 & 3 & 1 & 0 & 0 & 0 & \cdots \\ 1 & 4 & 6 & 4 & 1 & 0 & 0 & \cdots \\ 1 & 5 & 10 & 10 & 5 & 1 & 0 & \cdots \\ 1 & 6 & 15 & 20 & 15 & 6 & 1 & \cdots \\ 1 & 7 & 21 & 35 & 35 & 21 & 7 & \ddots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \end{bmatrix}$$

Then we have the sum identities

$$\sum_{j=0}^{i} a_{ij} = 2^i$$

$$\sum_{j=1}^{i} a_{ij} = 2^i - 1$$

$$\sum_{i=0}^{n} a_{ij} = a_{(n+1),(j+1)} = \frac{n+1}{j+1} a_{nj}.$$

Figures

A number x is said to have "n figures" if it takes n DIGITS to express it. The number of figures is therefore equal to one more than the POWER of 10 in the SCIENTIFIC NOTATION representation of the number. The word is most frequently used in reference to monetary amounts, e.g., a "six-figure salary" would fall in the range of \$100,000 to \$999,999.

See also DIGIT, SCIENTIFIC NOTATION, SIGNIFICANT FIGURES

Filon's Integration Formula

A formula for NUMERICAL INTEGRATION,

$$\int_{x_0}^{x_n} f(x)\cos(tx)\,dx = h\{\alpha(th)[f_{2n}\sin(tx_{2n}) - f_0\sin(tx_0)] + \beta(th)C_{2n} + \gamma(th)C_{2n-1} + \frac{2}{45}th^4 S'_{2n-1}\} - R_n, \quad (1)$$

where

$$C_{2n} = \sum_{i=0}^{n} f_{2i}\cos(tx_{2i}) - \frac{1}{2}[f_{2n}\cos(tx_{2n}) + f_0\cos(tx_0)] \quad (2)$$

$$C_{2n-1} = \sum_{i=1}^{n} f_{2i-1}\cos(tx_{2i-1}) \quad (3)$$

$$S'_{2n-1} = \sum_{i=1}^{n} f_{2i-1}^{(3)}\sin(tx_{2i}-1) \quad (4)$$

$$\alpha(\theta) = \frac{1}{\theta} + \frac{\sin(2\theta)}{2\theta^2} - \frac{2\sin^2\theta}{\theta^3} \quad (5)$$

$$\beta(\theta) = 2\left[\frac{1+\cos^2\theta}{\theta^2} - \frac{\sin(2\theta)}{\theta^3}\right] \quad (6)$$

$$\gamma(\theta) = 4\left(\frac{\sin\theta}{\theta^3} - \frac{\cos\theta}{\theta^2}\right), \quad (7)$$

and the remainder term is

$$R_n = \frac{1}{90} n h^5 f^{(4)}(\xi) + \mathcal{O}(th^7). \quad (8)$$

Filter

Let S be a nonempty set, then a filter on S is a nonempty collection F of subsets of S having the following properties:

1. $\emptyset \notin F$,
2. If $A, B \in F$, then $A \cap B \in F$,
3. If $A \in F$ and $A \subseteq B \subseteq S$ then $B \in F$

If S is an infinite set, then the collection $F_S = \{A \subseteq S : S - A \text{ is finite}\}$ is a filter called the COFINITE (or Fréchet) filter on S.

In signal processing, a filter is a function or procedure which removes unwanted parts of a signal. The concept of filtering and filter functions is particularly useful in engineering. One particularly elegant method of filtering FOURIER TRANSFORMS a signal into frequency space, performs the filtering operation there, then transforms back into the original space (Press *et al.* 1992).

Filtration

Fine's Equation

The Q-SERIES identity

$$\prod_{n=1} \frac{(1-q^{2n})(1-q^{3n})(1-q^{8n})(1-q^{12n})}{(1-q^n)(1-q^{24n})} = 1 + \sum_{N=1} E_{1,5,7,11}(N;24)q^N,$$

where $E_{1,5,7,11}(N;24)$ is the sum of the DIVISORS of N CONGRUENT to 1, 5, 7, and 11 (mod 24) minus the sum of DIVISORS of N CONGRUENT to -1, -5, -7, and -11 (mod 24).

See also Q-SERIES

Finite

A SET which contains a NONNEGATIVE integral number of elements is said to be finite. A SET which is not finite is said to be INFINITE. A finite or COUNTABLY INFINITE set is said to be COUNTABLE. While the meaning of the term "finite" is fairly clear in common usage, precise definitions of FINITE and INFINITE are needed in technical mathematics and especially in SET THEORY.

See also COUNTABLE SET, COUNTABLY INFINITE, INFINITE, SET THEORY, UNCOUNTABLY INFINITE

Finite Difference

The finite difference is the discrete analog of the DERIVATIVE. The finite FORWARD DIFFERENCE of a function f_p is defined as

$$\Delta f_p \equiv f_{p+1} - f_p, \tag{1}$$

and the finite BACKWARD DIFFERENCE as

$$\nabla f_p \equiv f_p - f_{p-1}. \tag{2}$$

If the values are tabulated at spacings h, then the notation

$$f_p \equiv f(x_0 + ph) \equiv f(x) \tag{3}$$

is used. The kth FORWARD DIFFERENCE would then be written as $\Delta^k f_p$, and similarly, the kth BACKWARD DIFFERENCE as $\nabla^k f_p$.

However, when f_p is viewed as a discretization of the continuous function $f(x)$, then the finite difference is sometimes written

$$\Delta f(x) \equiv f\left(x+\frac{1}{2}\right) - f\left(x-\frac{1}{2}\right) = 2\mathrm{I_I}(x) * f(x), \tag{4}$$

where $*$ denotes CONVOLUTION and $\mathrm{I_I}(x)$ is the odd IMPULSE PAIR. The finite difference operator can therefore be written

$$\tilde{\Delta} = 2\mathrm{I_I} *. \tag{5}$$

An nth POWER has a constant nth finite difference. For example, take $n=3$ and make a DIFFERENCE TABLE,

$$\begin{array}{cccccc} x & x^3 & & & & \\ 1 & 1 & \Delta & & & \\ & & 7 & \Delta^2 & & \\ 2 & 8 & & 12 & \Delta^3 & \\ & & 19 & & 6 & \Delta^4 \\ 3 & 27 & & 18 & & 0 \\ & & 37 & & 6 & \\ 4 & 64 & & 24 & & \\ & & 61 & & & \\ 5 & 125 & & & & \end{array}. \tag{6}$$

The Δ^3 column is the constant 6.

Finite difference formulas can be very useful for extrapolating a finite amount of data in an attempt to find the general term. Specifically, if a function $f(n)$ is known at only a few discrete values $n = 0, 1, 2, \ldots$ and it is desired to determine the analytical form of f, the following procedure can be used if f is assumed to be a POLYNOMIAL function. Denote the nth value in the SEQUENCE of interest by a_n. Then define b_n as the FORWARD DIFFERENCE $\Delta_n \equiv a_{n+1} - a_n$, c_n as the second FORWARD DIFFERENCE $\Delta_n^2 \equiv b_{n+1} - b_n$, etc., constructing a table as follows

$$\begin{array}{cccc} a_0 \equiv f(0) & a_1 \equiv f(1) & a_2 \equiv f(2) \quad \ldots & a_p \equiv f(p) \\ b_0 \equiv a_1 - a_0 & b_1 \equiv a_2 - a_1 & \ldots & b_{p-1} \equiv a_p - a_{p-1} \\ & c_0 \equiv b_1 - b_0 & \ldots & \ldots \\ & & \ddots & \end{array} \tag{7}$$

Continue computing d_0, e_0, etc., until a 0 value is obtained. Then the POLYNOMIAL function giving the values a_n is given by

$$f(n) = \sum_{k=0}^{p} a_k \binom{n}{k} = a_0 + b_0 n + \frac{c_0 n(n-1)}{2} + \frac{d_0 n(n-1)(n-2)}{2 \cdot 3} + \ldots \tag{8}$$

When the notation $\Delta_0 \equiv a_0$, $\Delta_0^2 \equiv b_0$, etc., is used, this beautiful equation is called NEWTON'S FORWARD DIFFERENCE FORMULA. To see a particular example, consider a SEQUENCE with first few values of 1, 19, 143, 607, 1789, 4211, and 8539. The difference table is then given by

$$\begin{array}{ccccccc} 1 & 19 & 143 & 607 & 1789 & 4211 & 8539 \\ & 18 & 124 & 464 & 1182 & 2422 & 4328 \\ & & 106 & 340 & 718 & 1240 & 1906 \\ & & & 234 & 378 & 522 & 666 \end{array}$$

144 144 144

0 0

Reading off the first number in each row gives $a_0 = 1$, $b_0 = 18$, $c_0 = 106$, $d_0 = 234$, $e_0 = 144$. Plugging these in gives the equation

$$f(n) = 1 + 18n + 53n(n-1) + 39n(n-1)(n-2) + 6n(n-1)(n-2)(n-3), \quad (9)$$

which simplifies to $f(n) = 6n^4 + 3n^3 + 2n^2 + 7n + 1$, and indeed fits the original data exactly!

Beyer (1987) gives formulas for the derivatives

$$h^n \frac{d^n f(x_0 + ph)}{dx^n} \equiv h^n \frac{d^n f_p}{dx^n} \equiv \frac{d^n f_p}{dp^n} \quad (10)$$

(Beyer 1987, pp. 449–51) and integrals

$$\int_{x_0}^{x_\infty} f(x)dx = h \int_0^n f_p dp \quad (11)$$

(Beyer 1987, pp. 455–56) of finite differences.

Finite differences lead to DIFFERENCE EQUATIONS, finite analogs of DIFFERENTIAL EQUATIONS. In fact, UMBRAL CALCULUS displays many elegant analogs of well-known identities for continuous functions. Common finite difference schemes for PARTIAL DIFFERENTIAL EQUATIONS include the so-called Crank-Nicholson, Du Fort-Frankel, and Laasonen methods.

Finite Element Method

A method for solving an equation by approximating continuous quantities as a set of quantities at discrete points, often regularly spaced into a so-called GRID or MESH. Because finite element methods can be adapted to problems of great complexity and unusual geometry, they are an extremely powerful tool in the solution of important problems in heat transfer, fluid mechanics, and mechanical systems. Furthermore, the availability of fast and inexpensive computers allows problems which are intractable using analytic or mechanical methods to be solved in a straightforward manner using finite element methods.

Finite Field

A finite field is a FIELD with a finite ORDER (number of elements), also called a Galois field. The order of a finite field is always a PRIME or a POWER of a PRIME (Birkhoff and Mac Lane 1996). For each PRIME POWER, there exists exactly one (with the usual caveat that "exactly one" means "exactly one up to an ISOMORPHISM") finite field GF(p^n), often written as $\mathbb{F}_{p^n}$ in current usage.

GF(p) is called the PRIME FIELD of order p, and is the FIELD of RESIDUE CLASSES modulo p, where the p elements are denoted 0, 1, ..., $p-1$. $a = b$ in GF(p) means the same as $a \equiv b (\mathrm{mod} p)$. Note, however, that $2 \times 2 \equiv 0 (\mathrm{mod} 4)$ in the RING of residues modulo 4, so 2 has no reciprocal, and the RING of residues modulo 4 is distinct from the finite field with four elements. Finite fields are therefore denoted GF(p^n), instead of GF(k), where $k = p^n$, for clarity.

The finite field GF(2) consists of elements 0 and 1 which satisfy the following addition and multiplication tables.

+	0	1
0	0	1
1	1	0

×	0	1
0	0	0
1	0	1

If a subset S of the elements of a finite field F satisfies the axioms above with the same operators of F, then S is called a SUBFIELD. Finite fields are used extensively in the study of ERROR-CORRECTING CODES.

When $n > 1$, GF(p^n) can be REPRESENTED AS the FIELD of EQUIVALENCE CLASSES of POLYNOMIALS whose COEFFICIENTS belong to GF(p). Any IRREDUCIBLE POLYNOMIAL of degree n yields the same FIELD up to an ISOMORPHISM. For example, for GF(2^3), the modulus can be taken as $x^3 + x^2 + 1$, $x^3 + x + 1$, or any other IRREDUCIBLE POLYNOMIAL of degree 3. Using the modulus $x^3 + x + 1$, the elements of GF(2^3)–written 0, x^0, x^1, ...–can be REPRESENTED AS POLYNOMIALS with degree less than 3. For instance,

$$x^3 \equiv -x - 1 \equiv x + 1$$

$$x^4 \equiv x(x^3) \equiv x(x+1) \equiv x^3 + x$$

$$x^5 \equiv x(x^2 + x) \equiv x^3 + x^2 \equiv x^2 - x - 1 \equiv x^2 + x + 1$$

$$x^6 \equiv x(x^2 + x + 1) \equiv x^3 + x^2 + x \equiv x^2 - 1 \equiv x^2 + 1$$

$$x^7 \equiv x(x^2 + 1) \equiv x^3 + x \equiv -1 \equiv 1 \equiv x_0.$$

Now consider the following table which contains several different representations of the elements of a finite field. The columns are the power, polynomial representation, triples of polynomial representation COEFFICIENTS (the vector representation), and the binary INTEGER corresponding to the vector representation (the regular representation).

Power	Polynomial	Vector	Regular
0	0	(000)	0
x^0	1	(001)	1
x^1	x	(010)	2
x^2	x^2	(100)	4
x^3	$x+1$	(011)	3
x^4	x^2+x	(110)	6
x^5	x^2+x+1	(111)	7
x^6	x^2+1	(101)	5

The set of POLYNOMIALS in the second column is CLOSED under ADDITION and MULTIPLICATION modulo $x^3 + x + 1$, and these operations on the set satisfy the AXIOMS of finite field. This particular finite field is said to be an extension field of degree 3 of GF(2), written GF(2^3), and the field GF(2) is called the base field of GF(2^3). If an IRREDUCIBLE POLYNOMIAL generates all elements in this way, it is called a PRIMITIVE POLYNOMIAL. For any PRIME or PRIME POWER q and any POSITIVE INTEGER n, there exists a primitive irreducible polynomial of degree n over GF(q).

For any element c of GF(q), $c^q = c$, and for any NONZERO element d of GF(q), $d^{q-1} = 1$. There is a smallest POSITIVE INTEGER n satisfying the sum condition $\underbrace{e + e + \ldots + e = 0}_{n \text{ times}}$ for some element e in GF(q),. This number is called the CHARACTERISTIC of the finite field GF(q). The CHARACTERISTIC is a PRIME NUMBER for every finite field, and it is true that

$$(x + y)^p = x^p + y^p$$

over a finite field with characteristic p.

Finite Group

A GROUP of finite ORDER. Examples of finite groups are the MODULO MULTIPLICATION GROUPS and the POINT GROUPS. The CLASSIFICATION THEOREM of finite SIMPLE GROUPS states that the finite SIMPLE GROUPS can be classified completely into one of five types.

The following table gives the numbers and names of the first few groups of ORDER h. In the table, *NA* denotes the number of non-Abelian groups, A denotes the number of ABELIAN GROUPS, and N the total number of groups. In addition, $\mathbb{Z}_n$ denotes a CYCLIC GROUP of ORDER n, A_n an ALTERNATING GROUP, D_n a DIHEDRAL GROUP, Q_8 the group of the QUATERNIONS, T the cubic group, and $\times$ denotes GROUP DIRECT PRODUCT.

h	Name	A	NA	N
1	FINITE GROUP E	1	0	1
2	FINITE GROUP $Z2$	1	0	1
3	FINITE GROUP $Z3$	1	0	1
4	FINITE GROUP $Z2\,Z2$, FINITE GROUP $Z4$	2	0	2
5	FINITE GROUP $Z5$	1	0	1
6	FINITE GROUP $Z6$, FINITE GROUP $D3$	1	1	2
7	FINITE GROUP $Z7$	1	0	1
8	FINITE GROUP $Z2\,Z2\,Z2$, FINITE GROUP $Z2\,Z4$, FINITE GROUP $Z8$, FINITE GROUP $Q8$, FINITE GROUP $D4$	3	2	5
9	$\mathbb{Z}_3 \times \mathbb{Z}_3, \mathbb{Z}_9$	2	0	2
10	$\mathbb{Z}_{10}, D_5$	1	1	2
11	$\mathbb{Z}_{11}$	1	0	1
12	$\mathbb{Z}_2 \times \mathbb{Z}_6, \mathbb{Z}_{12}, A_4, D_6, T$	2	3	5
13	$\mathbb{Z}_{13}$	1	0	1
14	$\mathbb{Z}_{14}, D_7$	1	1	2
15	$\mathbb{Z}_{15}$	1	0	1

The problem of determining the nonisomorphic finite groups of order h was first considered by Cayley (1854). There is no known FORMULA to give the number of possible finite groups $g(h)$ as a function of the ORDER h. However, there are simple formulas for special forms of h.

$$g(1) = 1 \tag{1}$$

$$g(p) = 1 \tag{2}$$

$$g(pq) = \begin{cases} 1 & \text{if } p \nmid (q-1) \\ 2 & \text{if } p \mid (q-1) \end{cases} \tag{3}$$

$$g(p^2) = 2 \tag{4}$$

$$g(p^3) = 5, \tag{5}$$

where p and $q > p$ are distinct primes. In addition, there is a beautiful algorithm due to Hölder (Hölder 1895, Alonso 1976) for determining $g(h)$ for square-free h, namely

$$g(h) = \sum_{d|n} \prod_{\substack{p|d \\ p \neq 1}} \frac{p^{o_p(n/d)} - 1}{p - 1}, \tag{6}$$

where $o_p(m)$ is the number of primes p such that $q|m$ and $p|(q-1)$ (Dennis).

Miller (1930) gave the number of groups for orders 1–00, including an erroneous 297 as the number of groups of ORDER 64. Senior and Lunn (1934, 1935) subsequently completed the list up to 215, but omitted 128 and 192. The number of groups of ORDER 64 was corrected in Hall and Senior (1964). James *et al.* (1990) found 2328 groups in 115 ISOCLINISM families of ORDER 128, correcting previous work, and O'Brien (1991) found the number of groups of ORDER 256. Currently, the number of groups is known for orders up to 2000, excluding 1024 (Besche and Eick 1999a), with the difficult cases of orders 512 ($g(512) = 10, 494, 213$; Eick and O'Brien 1999b) and 768 (Besche and Eick 2000) now put to rest. The numbers of nonisomorphic finite groups N of each ORDER h for the first few hundred orders are given in the table below (Sloane's A000001–the very first sequence). The number of nonisomorphic groups of orders 2^n for $n = 0$, 1, ... are 1, 1, 2, 5, 14, 51, 267, 2328, 56092, ... (Sloane's A000679).

The smallest orders h for which there exist $n = 1, 2, \ldots$ nonisomorphic groups are 1, 4, 75, 28, 8, 42, ... (Sloane's A046057). The incrementally largest number of nonisomorphic finite groups are 1, 2, 5, 14, 15, 51, 52, 267, 2328, ... (Sloane's A046058), which occur for orders 1, 4, 8, 16, 24, 32, 48, 64, 128, ... (Sloane's A046059). Dennis has conjectured that the number of groups $g(h)$ of order h assumes every positive integer as a value an infinite number of times.

It is simple to determine the number of ABELIAN GROUPS using the KRONECKER DECOMPOSITION THEO-

REM, and there is at least one ABELIAN GROUP for every finite order h. The number A of ABELIAN GROUPS of ORDER $h = 1, 2, \ldots$ are given by 1, 1, 1, 2, 1, 1, 1, 3, ... (Sloane's A000688). The following table summarizes the total number of finite groups N and the number of Abelian finite groups A for orders h from 1 to 400. A table of orders up to 1000 is given by Royle; the GAP software package includes a table of the number of finite groups up to order 2000, excluding 1024.

Finite Group D3

D_3

The DIHEDRAL GROUP D_3 is one of the two groups of ORDER 6. It is the non-Abelian group of smallest ORDER. Examples of D_3 include the POINT GROUPS known as C_{3h}, C_{3v}, S_3, D_3, the symmetry group of the EQUILATERAL TRIANGLE, and the group of permutation of three objects. Its elements A_i satisfy $A_i^3 = 1$, and four of its elements satisfy $A_i^2 = 1$, where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is given below (Cotton 1990, p. 12).

D_3	1	A	B	C	D	E
1	1	A	B	C	D	E
A	A	1	D	E	B	C
B	B	E	1	D	C	A
C	C	D	E	1	A	B
D	D	C	A	B	E	1
E	E	B	C	A	1	D

The CONJUGACY CLASSES are $\{1\}$ (which is always in a class by itself), $\{A, B, C\}$,

$$A^{-1}AA = A \tag{1}$$

$$B^{-1}AB = C \tag{2}$$

$$C^{-1}AC = B \tag{3}$$

$$D^{-1}AD = C \tag{4}$$

$$E^{-1}AE = B, \tag{5}$$

and $\{D, E\}$,

$$A^{-1}DA = E \tag{6}$$

$$B^{-1}DB = D. \tag{7}$$

A reducible 2-D representation using REAL MATRICES can be found by performing the spatial rotations corresponding to the symmetry elements of C_{3v}. Take the z-AXIS along the C_3 axis.

$$I = R_z(0) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \tag{8}$$

$$A = R_z\left(\frac{2}{3}\Pi\right) = \begin{bmatrix} \cos\left(\frac{2}{3}\Pi\right) & \sin\left(\frac{2}{3}\Pi\right) \\ -\sin\left(\frac{2}{3}\Pi\right) & \cos\left(\frac{2}{3}\Pi\right) \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} & -\frac{1}{2}\sqrt{3} \\ \frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (9)$$

$$B = R_z\left(\frac{4}{3}\Pi\right) = \begin{bmatrix} -\frac{1}{2} & \frac{1}{2}\sqrt{3} \\ -\frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (10)$$

$$C = R_c(\Pi) = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} \quad (11)$$

$$D = R_D(\Pi) = CB = \begin{bmatrix} \frac{1}{2} & -\frac{1}{2}\sqrt{3} \\ -\frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (12)$$

$$E = R_E(\Pi) = CA = \begin{bmatrix} \frac{1}{2} & \frac{1}{2}\sqrt{3} \\ \frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (13)$$

To find the irreducible representation, note that there are three CONJUGACY CLASSES. GROUP rule 5 requires that there be three irreducible representations satisfying

$$h = l_1^2 + l_2^2 + l_3^2 = 6, \quad (14)$$

so it must be true that

$$l_1 = l_2 = 1, l_3 = 2. \quad (15)$$

By GROUP rule 6, we can let the first representation have all 1s.

D_3	1	A	B	C	D	E
Γ_1	1	1	1	1	1	1

To find a representation orthogonal to the totally symmetric representation, we must have three $+1$ and three -1 CHARACTERS. We can also add the constraint that the components of the IDENTITY ELEMENT 1 be positive. The three CONJUGACY CLASSES have 1, 2, and 3 elements. Since we need a total of three +1s and we have required that a +1 occur for the CONJUGACY CLASS of ORDER 1, the remaining +1s must be used for the elements of the CONJUGACY CLASS of ORDER 2, i.e., D and E.

D_3	1	A	B	C	D	E
Γ_1	1	1	1	1	1	1
Γ_2	1	-1	-1	-1	1	1

Using GROUP rule 1, we see that

$$1^2 + 1^2 + \chi_3^2(1) = 6 \quad (16)$$

so the final representation for 1 has CHARACTER 2. Orthogonality with the first two representations (GROUP rule 3) then yields the following constraints:

$$1 \cdot 1 \cdot 2 + 1 \cdot 2 \cdot \chi_2 + 1 \cdot 3 \cdot \chi_3 = 2 + 2\chi_2 + 3\chi_3 = 0 \quad (17)$$

$$1 \cdot 1 \cdot 2 + 1 \cdot 2 \cdot \chi_2 + (-1) \cdot 3 \cdot \chi_3 = 2 + 2\chi_2 - 3\chi_3 = 0. \quad (18)$$

Solving these simultaneous equations by adding and subtracting (18) from (17), we obtain $\chi_2 = -1$, $\chi_3 = 0$. The full CHARACTER TABLE is then

D_3	1	A	B	C	D	E
Γ_1	1	1	1	1	1	1
Γ_2	1	-1	-1	-1	1	1
Γ_3	2	0	0	0	-1	-1

Since there are only three CONJUGACY CLASSES, this table is conventionally written simply as

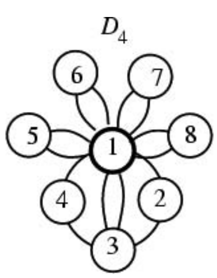
D_3	1	$A = B = C$	$D = E$
Γ_1	1	1	1
Γ_2	1	-1	1
Γ_3	2	0	-1

Writing the irreducible representations in matrix form then yields

$$1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (19)$$

$$A = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -\frac{1}{2} & -\frac{1}{2}\sqrt{3} \\ 0 & 0 & \frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (20)$$

$$B = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -\frac{1}{2} & \frac{1}{2}\sqrt{3} \\ 0 & 0 & -\frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (21)$$



$$C = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (22)$$

$$D = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -\frac{1}{2} & \frac{1}{2}\sqrt{3} \\ 0 & 0 & -\frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (23)$$

$$E = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & \frac{1}{2} & \frac{1}{2}\sqrt{3} \\ 0 & 0 & \frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (24)$$

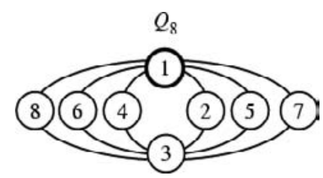
Finite Group D4

The DIHEDRAL GROUP D_4 is one of the two non-Abelian groups of the five groups total of ORDER 8. It is sometimes called the octic group. Examples of D_4 include the symmetry group of the SQUARE. The CYCLE GRAPH is shown above.

See also DIHEDRAL GROUP, FINITE GROUP D3, FINITE GROUP Z8, FINITE GROUP Z2Z2Z2, FINITE GROUP Z2Z4, FINITE GROUP Z8

References

Cotton, F. A. *Chemical Applications of Group Theory, 3rd ed.* New York: Wiley, 1990.



Finite Group e

The unique (and trivial) group of ORDER 1 is denoted $\langle e \rangle$. It is (trivially) ABELIAN and CYCLIC. Examples include the POINT GROUP C_1 and the integers modulo 1 under addition.

$\langle e \rangle$	1
1	1

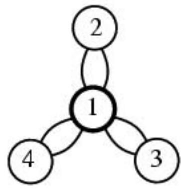
Its only conjugacy class is $\{1\}$.

Finite Group Q8

One of the two non-Abelian groups of the five groups total of ORDER 8. The group Q_8 has the MULTIPLICATION TABLE of $\pm 1, i, j, k$, where 1, i, j, and k are the QUATERNIONS. The CYCLE GRAPH is shown above.

See also FINITE GROUP D4, FINITE GROUP Z2Z2Z2, FINITE GROUP Z2Z4, FINITE GROUP Z8, QUATERNION

Finite Group Z2



The unique group of ORDER 2. $\mathbb{Z}_2$ is both ABELIAN and CYCLIC. Examples include the POINT GROUPS C_s, C_i, and C_2, the integers modulo 2 under addition, and the MODULO MULTIPLICATION GROUPS M_3, M_4, and M_6. The elements A_i satisfy $A_i^2 = 1$, where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is given below.

$\mathbb{Z}_2$	1	A
1	1	A
A	A	1

The CONJUGACY CLASSES are $\{1\}$ and $\{A\}$. The irreducible representation for the C_2 group is $\{1, -1\}$.

Finite Group Z2Z2

$Z_2 \otimes Z_2$

One of the two groups of ORDER 4. The name of this group derives from the fact that it is a GROUP DIRECT PRODUCT of two $\mathbb{Z}_2$ SUBGROUPS. Like the group $\mathbb{Z}_4$, $\mathbb{Z}_2 \times \mathbb{Z}_2$ is an ABELIAN GROUP. Unlike $\mathbb{Z}_4$, however, it is not CYCLIC. In addition to satisfying $A_i^4 = 1$ for each element A_i, it also satisfies $A_i^2 = 1$, where 1 is the IDENTITY ELEMENT. Examples of the $\mathbb{Z}_2 \times \mathbb{Z}_2$ group include the VIERGRUPPE, POINT GROUPS D_2, C_{2h}, and C_{2v}, and the MODULO MULTIPLICATION GROUPS M_8 and M_{12}. That M_8, the RESIDUE CLASSES prime to 8 given by $\{1, 3, 5, 7\}$, are a group of type $\mathbb{Z}_2 \times \mathbb{Z}_2$ can be shown by verifying that

$$1^2 = 1 \quad 3^2 = 9 \equiv 1 \quad 5^2 = 25 \equiv 1 \qquad 7^2 = 49 \equiv 1 \pmod 8 \tag{1}$$

and

$$3 \cdot 5 = 15 \equiv 7 \quad 3 \cdot 7 = 21 \equiv 5 \quad 5 \cdot 7 = 35 \equiv 3 \pmod 8. \tag{2}$$

$\mathbb{Z}_2 \times \mathbb{Z}_2$ is therefore a MODULO MULTIPLICATION GROUP.

The CYCLE GRAPH is shown above, and the multiplication table for the $\mathbb{Z}_2 \times \mathbb{Z}_2$ group is given below (Cotton 1990, p. 11).

$\mathbb{Z}_2 \times \mathbb{Z}_2$	1	A	B	C
1	1	A	B	C
A	A	1	C	B
B	B	C	1	A
C	C	B	A	1

The CONJUGACY CLASSES are $\{1\}$, $\{A\}$,

$$A^{-1}AA = A \tag{3}$$

$$B^{-1}AB = A \tag{4}$$

$$C^{-1}AC = A, \tag{5}$$

$\{B\}$,

$$A^{-1}BA = B \tag{6}$$

$$C^{-1}BC = B, \tag{7}$$

and $\{C\}$.

Now explicitly consider the elements of the C_{2v} POINT GROUP.

C_{2v}	E	C_2	σ_v	σ_v
E	E	C_2	σ_v	σ_v'
C_2	C_2	E	σ_v'	σ_v
σ_v	σ_v	σ_v'	E	C_2
σ_v'	σ_v'	σ_v	C_2	E

In terms of the VIERGRUPPE elements

V	I	V_1	V_2	V_3
I	V_1	V_2	V_3	V_4
V_1	V_1	I	V_3	V_2
V_2	V_2	V_3	I	V_1
V_3	V_3	V_2	V_1	I

A reducible representation using 2-D REAL MATRICES is

$$1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \tag{8}$$

$$A = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix} \tag{9}$$

$$B = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \tag{10}$$

$$C = \begin{bmatrix} 0 & -1 \\ -1 & 0 \end{bmatrix}. \tag{11}$$

Another reducible representation using 3-D REAL MATRICES can be obtained from the symmetry elements of the D_2 group (1, $C_2(z)$, $C_2(y)$, and $C_2(x)$) or C_{2v} group (1, C_2, σ_v, and σ_v'). Place the C_2 axis along the Z-AXIS, σ_v in the x-y plane, and σ_v' in the y-z plane.

$$1 = E = E = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{12}$$

$$A = R_x(\Pi) = \sigma_v = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{13}$$

$$C = R_z(\Pi) = C_2 = \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{14}$$

$$B = R_y(\Pi) = \sigma'_v = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}. \quad (15)$$

In order to find the irreducible representations, note that the traces are given by $\chi(1) = 3, \chi(C_2) = -1$ and $\chi(\sigma_v) = \chi(\sigma_v') = 1$ Therefore, there are at least three distinct CONJUGACY CLASSES. However, we see from the MULTIPLICATION TABLE that there are actually four CONJUGACY CLASSES, so GROUP rule 5 requires that there must be four irreducible representations. By GROUP rule 1, we are looking for POSITIVE INTEGERS which satisfy

$$l_1^2 + l_2^2 + l_3^2 + l_4^2 = 4. \quad (16)$$

The only combination which will work is

$$l_1 = l_2 = l_3 = l_4 = 1, \quad (17)$$

so there are four one-dimensional representations. GROUP rule 2 requires that the sum of the squares equal the ORDER $h = 4$, so each 1-D representation must have CHARACTER ± 1. GROUP rule 6 requires that a totally symmetric representation always exists, so we are free to start off with the first representation having all 1s. We then use orthogonality (GROUP rule 3) to build up the other representations. The simplest solution is then given by

C_{2v}	1	C_2	σ_v	σ'_v
Γ_1	1	1	1	1
Γ_2	1	-1	-1	1
Γ_3	1	-1	1	-1
Γ_4	1	1	-1	-1

These can be put into a more familiar form by switching Γ_1 and Γ_3, giving the CHARACTER TABLE

C_{2v}	1	C_2	σ_v	σ'_v
Γ_3	1	-1	1	-1
Γ_2	1	-1	-1	1
Γ_1	1	1	1	1
Γ_4	1	1	-1	-1

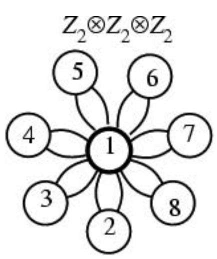
The matrices corresponding to this representation are now

$$1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (18)$$

$$C_2 = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (19)$$

$$\sigma_v = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (20)$$

$$\sigma_v{}' = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (21)$$



which consist of the previous representation with an additional component. These matrices are now orthogonal, and the order equals the matrix dimension. As before, $\chi(\sigma_v) = \chi(\sigma_v^1)$.

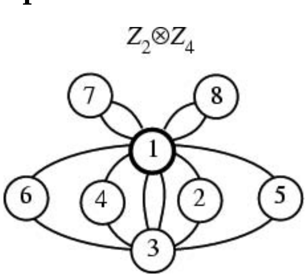
Cotton, F. A. *Chemical Applications of Group Theory, 3rd ed.* New York: Wiley, 1990.

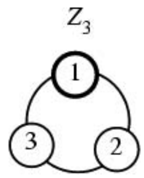


Finite Group Z2Z2Z2

One of the three Abelian groups of the five groups total of ORDER 8. Examples include the MODULO MULTIPLICATION GROUP M_{24}. The elements A_i of this group satisfy $A_i^2 = 1$, where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above.

See also FINITE GROUP $D4$, FINITE GROUP $Q8$, FINITE GROUP $Z2Z4$, FINITE GROUP $Z8$

Finite Group Z2Z4



One of the three Abelian groups of the five groups total of ORDER 8. Examples include the MODULO MULTIPLICATION GROUPS M_{15}, M_{16}, M_{20}, and M_{30}. The elements A_i of this group satisfy $A_i^4 = 1$, where

1 is the IDENTITY ELEMENT, and four of the elements satisfy $A_i^2 = 1$. The CYCLE GRAPH is shown above.

See also FINITE GROUP $D4$, FINITE GROUP $Q8$, FINITE GROUP $Z2Z2Z2$, FINITE GROUP $Z8$

Finite Group Z3

The unique group of ORDER 3. It is both ABELIAN and CYCLIC. Examples include the POINT GROUPS C_3 and D_3 and the integers under addition modulo 3. The elements A_i of the group satisfy $A_i^3 = 1$ where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is given below (Cotton 1990, p. 10).

$\mathbb{Z}_3$	1	A	B
1	1	A	B
A	A	B	1
B	B	1	A

The CONJUGACY CLASSES are $\{1\}$, $\{A\}$,

$$A^{-1}AA = A$$

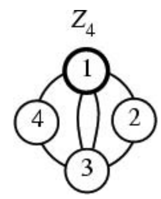
$$B^{-1}AB = A,$$

and $\{B\}$,

$$A^{-1}BA = B$$

$$B^{-1}BB = B.$$

The irreducible representation (CHARACTER TABLE) is therefore



Γ	1	A	B
Γ_1	1	1	1
Γ_2	1	1	-1
Γ_3	1	-1	1

Finite Group Z4

One of the two groups of ORDER 4. Like $\mathbb{Z}_2 \times \mathbb{Z}_2$, it is ABELIAN, but unlike $\mathbb{Z}_2 \times \mathbb{Z}_2$, it is a CYCLIC. Examples include the POINT GROUPS C_4 and S_4 and the MODULO MULTIPLICATION GROUPS M_5 and M_{10}. Elements A_i of the group satisfy $A_i^4 = 1$, where 1 is the IDENTITY ELEMENT, and two of the elements satisfy $A_i^2 = 1$. The CYCLE GRAPH is shown above. The MULTIPLICATION TABLE for this group may be written in three equivalent ways—denoted here by $\mathbb{Z}_4^{(1)}$, $\mathbb{Z}_4^{(2)}$, and $\mathbb{Z}_4^{(3)}$—by permuting the symbols used for the group elements. (Cotton 1990, p. 11).

$\mathbb{Z}_4^{(1)}$	1	A	B	C
1	1	A	B	C
A	A	B	C	1
B	B	C	1	A
C	C	1	A	B

The MULTIPLICATION TABLE for $\mathbb{Z}_4^{(2)}$ is obtained from $\mathbb{Z}_4^{(1)}$ by interchanging A and B.

$Z_4^{(2)}$	1	A	B	C
1	1	A	B	C
A	A	1	C	B
B	B	C	A	1
C	C	B	1	A

The MULTIPLICATION TABLE for $\mathbb{Z}_4^{(3)}$ is obtained from $\mathbb{Z}_4^{(1)}$ by interchanging A and C.

$\mathbb{Z}_4^{(3)}$	1	A	B	C
1	1	A	B	C
A	A	C	1	B
B	B	1	C	A
C	C	B	A	1

The CONJUGACY CLASSES of $\mathbb{Z}_4$ are $\{1\}$, $\{A\}$,

$$A^{-1}AA = A \quad (1)$$

$$B^{-1}AB = A \quad (2)$$

$$C^{-1}AC = A, \quad (3)$$

$\{B\}$,

$$A^{-1}BA = B \quad (4)$$

$$B^{-1}BB = B \quad (5)$$

$$C^{-1}BC = B, \quad (6)$$

and $\{C\}$.

The group may be given a reducible representation using COMPLEX NUMBERS

$$1 = 1 \quad (7)$$

$$A = i \quad (8)$$

$$B = -1 \quad (9)$$

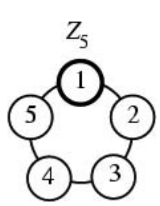
$$C = -i, \quad (10)$$

or REAL MATRICES

$$1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad (11)$$

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \quad (12)$$

$$B = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix} \quad (13)$$



$$C = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}. \quad (14)$$

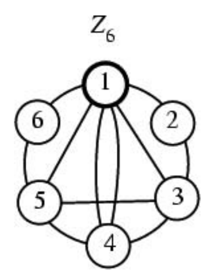
Cotton, F. A. *Chemical Applications of Group Theory, 3rd ed.* New York: Wiley, 1990.

Finite Group Z5



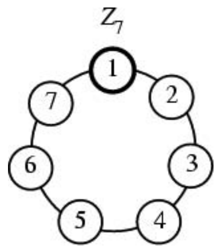
The unique GROUP of ORDER 5, which is ABELIAN. Examples include the POINT GROUP C_5 and the integers mod 5 under addition. The elements A_i satisfy $A_i^5 = 1$, where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is illustrated below.

$\mathbb{Z}_5$	1	A	B	C	D
1	1	A	B	C	D
A	A	B	C	D	1
B	B	C	D	1	A
C	C	D	1	A	B
D	D	1	A	B	C

The CONJUGACY CLASSES are $\{1\}$, $\{A\}$, $\{B\}$, $\{C\}$, and $\{D\}$.

See also CYCLIC GROUP

Finite Group Z6



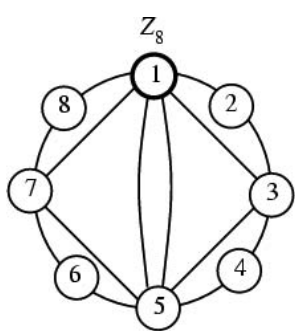
One of the two groups of ORDER 6 which, unlike D_3, is ABELIAN. It is also a CYCLIC. It is isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_3$.. Examples include the POINT GROUPS C_6 and S_6, the integers modulo 6 under addition, and the MODULO MULTIPLICATION GROUPS M_7, M_9, and M_{14}. The elements A_i of the group satisfy $A_i^6 = 1$, where 1 is the IDENTITY ELEMENT, three elements satisfy $A_i^3 = 1$, and two elements satisfy $A_i^2 = 1$. The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is given below.

$\mathbb{Z}_6$	1	A	B	C	D	E
1	1	A	B	C	D	E
A	A	B	C	D	E	1
B	B	C	D	E	1	A
C	C	D	E	1	A	B
D	D	E	1	A	B	C
E	E	1	A	B	C	D

The CONJUGACY CLASSES are $\{1\}$, $\{A\}$, $\{B\}$, $\{C\}$, $\{D\}$, and $\{E\}$.

See also CYCLIC GROUP, FINITE GROUP D_3

Finite Group Z7



The unique GROUP of ORDER 7. It is ABELIAN and CYCLIC. Examples include the POINT GROUP C_7 and the integers modulo 7 under addition. The elements A_i of the group satisfy $A_i^7 = 1$, where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above.

$\mathbb{Z}_7$	1	A	B	C	D	E	F
1	1	A	B	C	D	E	F
A	A	B	C	D	E	F	1
B	B	C	D	E	F	1	A
C	C	D	E	F	1	A	B
D	D	E	F	1	A	B	C
E	E	F	1	A	B	C	D
F	F	1	A	B	C	D	E

The CONJUGACY CLASSES are $\{1\}$, $\{A\}$, $\{B\}$, $\{C\}$, $\{D\}$, $\{E\}$, and $\{F\}$.

See also CYCLIC GROUP

Finite Group Z8

One of the three Abelian groups of the five groups total of ORDER 8. An example is the residue classes modulo 17 which QUADRATIC RESIDUES, i.e., $\{1, 2, 4, 8, 9, 13, 15, 16\}$ under multiplication modulo 17. The elements A_i satisfy $A_i^8 = 1$, four of them satisfy $A_i^4 = 1$, and two satisfy $A_i^2 = 1$. The CYCLE GRAPH is shown above.

Finite Order

An ENTIRE FUNCTION f is said to be of finite order if there exist numbers $a, r > 0$ such that

$$|f(z)| \leq \exp(|z|^a)$$

for all $|z| > r$. The INFIMUM of all numbers a for which this inequality holds is called the ORDER of f, denoted $\lambda = \lambda(f)$.

PROJECTIVE PLANE

Finite Simple Group

SIMPLE GROUP

Finite Simple Group Classification Theorem

CLASSIFICATION THEOREM

Finitely Generated

A GROUP G is said to be finitely generated if there exists a finite set of GENERATORS for G.

See also GENERATOR (GROUP)

Finite-to-One Factor

A MAP $\psi : M \to M$, where M is a MANIFOLD, is a finite-to-one factor of a MAP $\Psi : X \to X$ if there exists a

continuous ONTO MAP $\Pi : X \to M$ such that $\psi \circ \Pi = \Pi \circ \Psi$ and $\Pi^{-1}(x) \subset X$ is finite for each $x \in M$.

Finsler Geometry

The geometry of FINSLER SPACE.

Finsler Manifold

FINSLER SPACE

Finsler Metric

A continuous real function $L(x,y)$ defined on the TANGENT BUNDLE $T(M)$ of an n-D DIFFERENTIABLE MANIFOLD M is said to be a Finsler metric if

1. $L(x,y)$ is DIFFERENTIABLE at $x \neq y$,
2. $L(x, \lambda y) = |\lambda| L(x,y)$ for any element $(x,y) \in T(M)$ and any REAL NUMBER λ,
3. Denoting the METRIC

$$g_{ij}(x,y) = \frac{1}{2} \frac{\partial^2 [L(x,y)]^2}{\partial y^i \partial y^j},$$

then g_{ij} is a POSITIVE DEFINITE MATRIX.

A DIFFERENTIABLE MANIFOLD M with a Finsler metric is called a FINSLER SPACE.

See also DIFFERENTIABLE MANIFOLD, FINSLER SPACE, TANGENT BUNDLE

Iyanaga, S. and Kawada, Y. (Eds.). "Finsler Spaces." §161 in *Encyclopedic Dictionary of Mathematics.* Cambridge, MA: MIT Press, pp. 540–42, 1980.

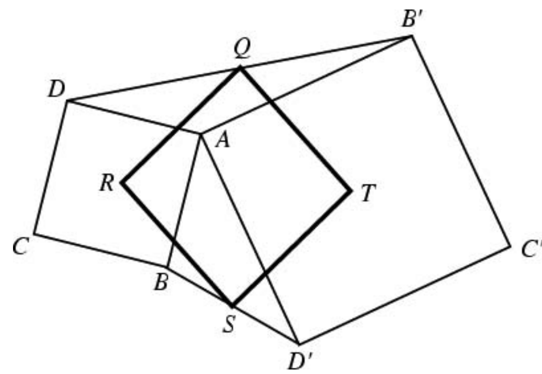
Finsler Space

A general space based on the LINE ELEMENT

$$ds = F\left(x^1, \ldots, x^n; dx^1, \ldots, dx^n\right),$$

with $F(x,y) > 0$ for $y \neq 0$ a function on the TANGENT BUNDLE $T(M)$, and homogeneous of degree 1 in y. Formally, a Finsler space is a DIFFERENTIABLE MANIFOLD possessing a FINSLER METRIC. Finsler geometry is RIEMANNIAN GEOMETRY *without* the restriction that the LINE ELEMENT be quadratic and OF THE FORM

$$F^2 = g_{ij}(x) dx^i dx^j.$$



A compact boundaryless Finsler space is locally Minkowskian IFF it has 0 "flag curvature."

First Curvature

CURVATURE

First Derivative Test

Suppose $f(x)$ is CONTINUOUS at a STATIONARY POINT x_0.

1. If $f'(x) > 0$ on an OPEN INTERVAL extending left from x_0 and $f'(x) < 0$ on an OPEN INTERVAL extend-

ing right from x_0, then $f(x)$ has a RELATIVE MAXIMUM (possibly a GLOBAL MAXIMUM) at x_0.

2. If $f'(x) < 0$ on an OPEN INTERVAL extending left from x_0 and $f'(x) > 0$ on an OPEN INTERVAL extending right from x_0, then $f(x)$ has a RELATIVE MINIMUM (possibly a GLOBAL MINIMUM) at x_0.

3. If $f'(x)$ has the same sign on an OPEN INTERVAL extending left from x_0 and on an OPEN INTERVAL extending right from x_0, then $f(x)$ does not have a RELATIVE EXTREMUM at x_0.

See also EXTREMUM, GLOBAL MAXIMUM, GLOBAL MINIMUM, INFLECTION POINT, MAXIMUM, MINIMUM, RELATIVE EXTREMUM, RELATIVE MAXIMUM, RELATIVE MINIMUM, SECOND DERIVATIVE TEST, STATIONARY POINT

First Digit Law

BENFORD'S LAW

First Digit Phenomenon

BENFORD'S LAW

First Fundamental Form

Let M be a REGULAR SURFACE with $\mathbf{v_p}, \mathbf{w_p}$ points in the TANGENT SPACE M_P of M. Then the first fundamental form is the INNER PRODUCT of tangent vectors,

$$\mathbf{I}(\mathbf{v_p}, \mathbf{w_p}) = \mathbf{v_p} \cdot \mathbf{w_p}. \qquad (1)$$

The first fundamental form satisfies

$$\mathbf{I}(a\mathbf{x}_u + b\mathbf{x}_v, a\mathbf{x}_u + b\mathbf{x}_v) = Ea^2 + 2Fab + Gb^2. \qquad (2)$$

The first fundamental form (or LINE ELEMENT) is given explicitly by the RIEMANNIAN METRIC

$$ds^2 = Edu^2 + 2Fdudv + Gdv^2. \qquad (3)$$

It determines the ARC LENGTH of a curve on a surface. The coefficients are given by

$$E = \mathrm{x}_{uu} = \left|\frac{\partial \mathrm{x}}{\partial u}\right|^2 \qquad (4)$$

$$F = \mathrm{x}_{uv} = \frac{\partial \mathrm{x}}{\partial u} \cdot \frac{\partial \mathrm{x}}{\partial v} \qquad (5)$$

$$G = \mathrm{x}_{vv} = \left|\frac{\partial \mathrm{x}}{\partial v}\right|^2. \qquad (6)$$

The coefficients are also denoted $g_{uu} = E$, $g_{uv} = F$, and $g_{vv} = G$. In CURVILINEAR COORDINATES (where $F = 0$), the quantities

$$h_u \equiv \sqrt{g_{uu}} = \sqrt{E} \qquad (7)$$

$$h_v \equiv \sqrt{g_{vv}} = \sqrt{G} \qquad (8)$$

are called SCALE FACTORS.

First Kind

Special functions which arise as solutions to second order ordinary differential equations are commonly said to be "of the first kind" if they are *nonsingular* at the origin, while the corresponding linearly independent solutions which are *singular* are said to be "of the second kind." Common examples of functions of the first kind defined in this way include the BESSEL FUNCTION OF THE FIRST KIND, CHEBYSHEV POLYNOMIAL OF THE FIRST KIND, CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND, HANKEL FUNCTION OF THE FIRST KIND, and so on.

The term "first kind" is also used in a more general context to distinguish between two or more types of mathematical objects which, however, all satisfy some common overall property. Examples of objects of this kind include the CHRISTOFFEL SYMBOL OF THE FIRST KIND, ELLIPTIC INTEGRAL OF THE FIRST KIND, FREDHOLM INTEGRAL EQUATION OF THE FIRST KIND, STIRLING NUMBER OF THE FIRST KIND, VOLTERRA INTEGRAL EQUATION OF THE FIRST KIND, and so on.

See also BESSEL FUNCTION OF THE FIRST KIND, CHEBYSHEV POLYNOMIAL OF THE FIRST KIND, CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND, ELLIPTIC INTEGRAL OF THE FIRST KIND, FREDHOLM INTEGRAL EQUATION OF THE FIRST KIND, HANKEL FUNCTION OF THE FIRST KIND, SECOND KIND, SPECIAL FUNCTION, STIRLING NUMBER OF THE FIRST KIND, THIRD KIND, VOLTERRA INTEGRAL EQUATION OF THE FIRST KIND

First Multiplier Theorem

Let D be a planar Abelian DIFFERENCE SET and t be any DIVISOR of n. Then t is a numerical multiplier of D, where a multiplier is defined as an automorphism α of a GROUP G which takes D to a translation $g + D$ of itself for some $g \in G$. If α is OF THE FORM $\alpha : x \to tx$ for $t \in \mathbb{Z}$ relatively prime to the order of G, then α is called a numerical multiplier.

Fisher Kurtosis

$$\gamma_2 \equiv b_2 \equiv \frac{\mu_4}{\mu_2^2} - 3 = \frac{\mu_4}{\sigma^4} - 3,$$

where μ_i is the ith MOMENT about the MEAN and $\sigma = \sqrt{\mu_2}$ is the STANDARD DEVIATION.

See also FISHER SKEWNESS, KURTOSIS, PEARSON KURTOSIS

Fisher Sign Test

A robust nonparametric test which is an alternative to the PAIRED t-TEST. This test makes the basic assumption that there is information only in the signs of the differences between paired observations, not in their sizes. Take the paired observations, calculate the differences, and count the number of +s$^{n_+}$ and –s $^{n_-}$, where

$$N \equiv n_+ + n_-$$

is the sample size. Calculate the BINOMIAL COEFFICIENT

$$B \equiv \binom{N}{n_+}.$$

Then $B/2^N$ gives the probability of getting exactly this many $+$s and $-$s if POSITIVE and NEGATIVE values are equally likely. Finally, to obtain the P-VALUE for the test, sum all the COEFFICIENTS that are $\leq B$ and divide by 2^N.

See also HYPOTHESIS TESTING

Fisher Skewness

$$\gamma_1 = \frac{\mu_3}{\mu_2^{3/2}} = \frac{\mu_3}{\sigma^3},$$

where μ_i is the i MOMENT about the MEAN, and $\sigma = \sqrt{\mu_2}$ is the STANDARD DEVIATION.

See also FISHER KURTOSIS, MOMENT, SKEWNESS, STANDARD DEVIATION

Fisher's Block Design Inequality

A balanced incomplete BLOCK DESIGN (v, k, λ, r, b) exists only for $b \geq v$ (or, equivalently, $r \geq k$).

Fisher's Estimator Inequality

Given T an UNBIASED ESTIMATOR of θ so that $\langle T \rangle = \theta$. Then

$$\mathrm{var}(T) \geq \frac{1}{N \int_{-\infty}^{\infty} \left[\frac{\partial(\ln f)}{\partial\theta}\right]^2 f\,dx},$$

where var is the VARIANCE.

Fisher's Exact Test

A STATISTICAL TEST used to determine if there are nonrandom associations between two CATEGORICAL VARIABLES.

Let there exist two such variables X and Y, with m and n observed states, respectively. Now form an $n \times m$ MATRIX in which the entries a_{ij} represent the number of observations in which $x = i$ and $y = j$. Calculate the row and column sums R_i and C_j, respectively, and the total sum

$$N = \sum_i R_i = \sum_j C_j \tag{1}$$

of the MATRIX. Then calculate the CONDITIONAL PROBABILITY of getting the actual matrix given the particular row and column sums, given by

$$P_{\mathrm{cutoff}} = \frac{(R_1!R_2!\ldots R_m!)(C_1!C_2!\ldots C_n!)}{N!\prod_{i,j} a_{ij}!}, \tag{2}$$

which is a multivariate generalization of the HYPERGEOMETRIC probability function. Now find all possible MATRICES of NONNEGATIVE INTEGERS consistent with the row and column sums R_i and C_j. For each one, calculate the associated CONDITIONAL PROBABILITY using (2), where the sum of these probabilities must be 1.

To compute the P-VALUE of the test, the tables must then be ordered by some criterion that measures dependence, and those tables that represent equal or greater deviation from independence than the observed table are the ones whose probabilities are added together. There are a variety of criteria that can be used to measure dependence. In the 2×2 case, which is the one Fisher looked at when he developed the exact test, either the Pearson chi-square or the difference in proportions (which are equivalent) is typically used. Other measures of association, such as the likelihood-ratio-test, G-squared, or any of the other measures typically used for association in contingency tables, can also be used.

The test is most commonly applied to 2×2 MATRICES, and is computationally unwieldy for large m or n. For tables larger than 2×2, the difference in proportion can no longer be used, but the other measures mentioned above remain applicable (and in practice, the Pearson statistic is most often used to order the tables). In the case of the 2×2 matrix, the P-VALUE of the test can be simply computed by the sum of all P-values which are $\leq P_{\mathrm{cutoff}}$.

For an example application of the 2×2 test, let X be a journal, say either *Mathematics Magazine* or *Science*, and let Y be the number of articles on the topics of mathematics and biology appearing in a given issue of one of these journals. If *Mathematics Magazine* has five articles on math and one on biology, and *Science* has none on math and four on biology, then the relevant matrix would be

	Math. Mag.	Science	
math	5	0	$R_1 = 5$
biology	1	4	$R_2 = 5$
	$C_1 = 6$	$C_2 = 4$	$N = 10.$

Computing P_{cutoff} gives

$$P_{\mathrm{cutoff}} = \frac{5!^2 6!4!}{10!(5!0!1!4!)} = 0.0238,$$

and the other possible matrices and their Ps are

$$\begin{bmatrix} 4 & 1 \\ 2 & 3 \end{bmatrix} \quad P = 0.2381$$

$$\begin{bmatrix} 3 & 2 \\ 3 & 2 \end{bmatrix} \quad P = 0.4762$$

$$\begin{bmatrix} 2 & 3 \\ 4 & 1 \end{bmatrix} \quad P = 0.2381$$

$$\begin{bmatrix} 1 & 4 \\ 5 & 0 \end{bmatrix} \quad P = 0.0238,$$

which indeed sum to 1, as required. The sum of P-values less than or equal to $P_{\mathrm{cutoff}} = 0.0238$ is then 0.0476 which, because it is less than 0.05, is SIGNIFICANT. Therefore, in this case, there would be a statistically significant association between the journal and type of article appearing.

Fisher's Theorem

Let A be a sum of squares of n independent normal standardized variates x_i, and suppose $A = B + C$ where B is a quadratic form in the x_i, distributed as CHI-SQUARED with h DEGREES OF FREEDOM. Then C is distributed as χ^2 with $n - h$ DEGREES OF FREEDOM and is independent of B. The converse of this theorem is known as COCHRAN'S THEOREM.

See also CHI-SQUARED DISTRIBUTION, COCHRAN'S THEOREM

Fisher's z'-Transformation

Let r be the CORRELATION COEFFICIENT. Then defining

$$z' \equiv \tanh^{-1} r \tag{1}$$

$$\zeta \equiv \tanh^{-1} p, \tag{2}$$

gives

$$\sigma_{z'} = (N-3)^{-1/2} \quad (3)$$

$$\operatorname{var}(z') = \frac{1}{n} + \frac{4-\rho^2}{2n^2} + \ldots \quad (4)$$

$$\gamma_1 = \frac{\rho\left|\rho^2 - \frac{9}{16}\right|}{n^{3/2}} \quad (5)$$

$$\gamma_2 = \frac{32-3\rho^4}{16N}, \quad (6)$$

where $n \equiv N-1$.

See also Correlation Coefficient

References

David, F. N. "The Moments of the z and F Distributions." *Biometrika* **36**, 394–03, 1949.

Fisher's z-Distribution

$$g(z) = \frac{2n_1^{n_1/2} n_2^{n_2/2}}{B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)} \frac{e^{n_1 z}}{(n_1 e^{2z} + n_2)^{(n_1+n_1)/2}} \quad (1)$$

(Kenney and Keeping 1951). This general distribution includes the chi-squared distribution and Student's t-distribution as special cases. Let u^2 and v^2 be independent unbiased estimators of the variance of a normally distributed variate. Define

$$z \equiv \ln\left(\frac{u}{v}\right) = \frac{1}{2}\ln\left(\frac{u^2}{v^2}\right). \quad (2)$$

Then let

$$F \equiv \frac{u^2}{v^2} = \frac{\frac{Ns_1^2}{n_1}}{\frac{Ns_2^2}{n_2}} \quad (3)$$

so that n_1F/n_2 is a ratio of chi-squared variates

$$\frac{n_1F}{n_2} = \frac{\chi^2(n_1)}{\chi^2(n_2)}, \quad (4)$$

which makes it a ratio of gamma distribution variates, which is itself a beta prime distribution variate,

$$\frac{\gamma\left(\frac{n_1}{2}\right)}{\gamma\left(\frac{n_2}{2}\right)} = \beta'\left(\frac{n_1}{2}, \frac{n_2}{2}\right) \quad (5)$$

giving

$$f(F) = \frac{\left(\frac{n_1F}{n_2}\right)^{n_1/2-1}\left(1+\frac{n_1F}{n_2}\right)^{-(n_1+n_2)/2}\frac{n_1}{n_2}}{B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)}. \quad (6)$$

The mean is

$$\langle F\rangle = \frac{n2}{n_2-2}, \quad (7)$$

and the mode is

$$\frac{n_2}{n_2+2}\frac{n_1-2}{n_1}. \quad (8)$$

Fisher-Tippett Distribution

Also called the EXTREME VALUE DISTRIBUTION and LOG-WEIBULL DISTRIBUTION. It is the limiting distribution for the smallest or largest values in a large sample drawn from a variety of distributions.

$$P(x)=\frac{e^{(a-x)/b-e^{(a-x)/b}}}{b} \tag{1}$$

$$D(x)=e^{-e(a-x)/b}. \tag{2}$$

These can be computed directly be defining

$$z \equiv \exp\left(\frac{a-x}{b}\right) \tag{3}$$

$$x=a-b\ln z \tag{4}$$

$$dz=-\frac{1}{b}\exp\left(\frac{a-x}{b}\right)dx. \tag{5}$$

Then the MOMENTS about the origin are

$$\mu'_n \equiv \int_{-\infty}^{\infty} x^n P(x)dx$$

$$=\frac{1}{b}\int_{-\infty}^{\infty} x^n \exp\left(\frac{a-x}{b}\right)\exp\left[-e^{(a-x)/b}\right]dx$$

$$=-\int_{\infty}^{0}(a-b\ln z)^n e^{-z}dz$$

$$=\int_{0}^{\infty}(a-b\ln z)^n e^{-z}dz$$

$$=\sum_{k=0}^{n}\binom{n}{k}(-1)^k a^{n-k}b^k\int_0^{\infty}(\ln z)^k e^{-z}dz$$

$$=\sum_{k=0}^{n}\binom{n}{k}a^{n-k}b^k I(k), \tag{6}$$

where $I(k)$ are EULER-MASCHERONI INTEGRALS. Plugging in the EULER-MASCHERONI INTEGRALS $I(k)$ gives

$$\mu'_0=1 \tag{7}$$

$$\mu'_1=a+b\gamma \tag{8}$$

$$\mu'_2=a^2+2ab\gamma+b^2\left(\gamma^2+\frac{1}{6}\pi^2\right) \tag{9}$$

$$\mu'_3=a^3+3a^2b\gamma+3ab^2\left(\gamma^2+\frac{1}{6}\pi^2\right)+b^3\left[\gamma^3+\frac{1}{2}\gamma\pi^2+2\zeta(3)\right] \tag{10}$$

$$\mu'_4=a^4+4a^3b\gamma+6a^2b^2\left(\gamma^2+\frac{1}{6}\pi^2\right)+4ab^3\left[\gamma^3+\frac{1}{2}\gamma\pi^2+2\zeta(3)\right]+b^4\left[\gamma^4+\gamma^2\pi^2+\frac{3}{20}\pi^4+8\gamma\zeta(3)\right], \tag{11}$$

where γ is the EULER-MASCHERONI CONSTANT and $\zeta(3)$ is APÉRY'S CONSTANT. The corresponding moments about the mean $\mu=\mu'_1$ are therefore

$$\mu_2=\frac{1}{6}b^2\pi^2 \tag{12}$$

$$\mu_3=2\zeta(3)b^3 \tag{13}$$

$$\mu_4=\frac{3}{20}b^4\pi^2, \tag{14}$$

giving MEAN, VARIANCE, SKEWNESS, and KURTOSIS of

$$\mu=a+b\gamma \tag{15}$$

$$\sigma^2=\mu_2-\mu_1^2=\frac{1}{6}\pi^2b^2 \tag{16}$$

$$\gamma_1=\frac{\mu_3}{\sigma^3}=\frac{12\sqrt{6}\zeta(3)}{\pi^3} \tag{17}$$

$$\gamma_2=\frac{\mu_4}{\sigma^4}-3=\frac{12}{5}. \tag{18}$$

The CHARACTERISTIC FUNCTION is

$$\phi(t)=\Gamma(1-i\beta t)e^{i\alpha t}, \tag{19}$$

where $\Gamma(z)$ is the GAMMA FUNCTION (Abramowitz and Stegun 1972, p. 930).
The special case of the Fisher-Tippett distribution with $a=0$, $b=1$ is called GUMBEL'S DISTRIBUTION.

See also EULER-MASCHERONI INTEGRALS, GUMBEL'S DISTRIBUTION

Fitting Subgroup

The unique smallest NORMAL NILPOTENT SUBGROUP of H, denoted $F(H)$. The generalized fitting subgroup is defined by $F^*(H)=F(H)E(H)$, where $E(H)$ is the commuting product of all components of H, and F is the fitting subgroup of H.

Fitzhugh-Nagumo Equations

The system of PARTIAL DIFFERENTIAL EQUATIONS

$$u_t = u_{xx} + u(u-a)(1-u) + w$$

$$w_t = eu.$$

Five Circles Theorem

MIQUEL FIVE CIRCLES THEOREM

Five Cubes

CUBE 5-COMPOUND

Five Disks Problem

Given five *equal* DISKS placed *symmetrically* about a given center, what is the smallest RADIUS r for which the RADIUS of the circular AREA covered by the five disks is 1? The answer is $r=\phi-1=1/\phi=0.6180339\ldots$, where ϕ is the GOLDEN RATIO, and the centers c_i of the disks $i = 1, ..., 5$ are located at

$$c_i = \begin{bmatrix} \frac{1}{\phi}\cos\left(\frac{2\pi i}{5}\right) \\ \frac{1}{\phi}\sin\left(\frac{2\pi i}{5}\right) \end{bmatrix}.$$

The GOLDEN RATIO enters here through its connection with the regular PENTAGON. If the requirement that the disks be symmetrically placed is dropped (the general DISK COVERING PROBLEM), then the RADIUS for $n=5$ disks can be reduced slightly to 0.609383... (Neville 1915).

Five Tetrahedra Compound

TETRAHEDRON 5-COMPOUND

Fixed

When referring to a planar object, "fixed" means that the object is regarded as fixed in the plane so that it may not be picked up and flipped. As a result, MIRROR IMAGES are not necessarily equivalent for fixed objects.

See also FREE, MIRROR IMAGE

Fixed Element

FIXED POINT (MAP)

Fixed Point

A point which does not change upon application of a MAP, system of DIFFERENTIAL EQUATIONS, etc.

See also FIXED POINT (DIFFERENTIAL EQUATIONS), FIXED POINT (GROUP), FIXED POINT (MAP), FIXED POINT THEOREM

References

Shashkin, Yu. A. *Fixed Points.* Providence, RI: Amer. Math. Soc., 1991.

Fixed Point (Differential Equations)

Points of an AUTONOMOUS system of ordinary differential equations at which

$$\begin{cases} \frac{dx_1}{dt} = f_1(x_1, \ldots, x_n) = 0 \\ \vdots \\ \frac{dx_n}{dt} = f_n(x_1, \ldots, x_n) = 0 \end{cases}$$

If a variable is slightly displaced from a FIXED POINT, it may (1) move back to the fixed point ("asymptotically stable" or "superstable"), (2) move away ("unstable"), or (3) move in a neighborhood of the fixed point but not approach it ("stable" but not "asymptotically stable"). Fixed points are also called CRITICAL POINTS or EQUILIBRIUM POINTS. If a variable starts at a point that is not a CRITICAL POINT, it cannot reach a critical point in a finite amount of time. Also, a trajectory passing through at least one point that is not a CRITICAL POINT cannot cross itself unless it is a CLOSED CURVE, in which case it corresponds to a periodic solution.

A fixed point can be classified into one of several classes using LINEAR STABILITY analysis and the resulting STABILITY MATRIX.

Fixed Point (Group)

The set of points of X fixed by a GROUP ACTION are called the group's set of fixed points, defined by

$$\{x : gx = x \text{ for all } g \in G\}.$$

In some cases, there may not be a group action, but a single operator T. Then $\{x{:}x \in X,\ Tx{=}x\}$ still makes sense even when T is not invertible (as is the case in a GROUP ACTION).

See also FIXED POINT, GROUP, GROUP ACTION

Fixed Point (Map)

A point x^* which is mapped to itself under a MAP G, so that $x^* = G(x^*)$. Such points are sometimes also called INVARIANT POINTS, or FIXED ELEMENTS (Woods 1961). Stable fixed points are called elliptical. Unstable fixed points, corresponding to an intersection of a stable and unstable invariant MANIFOLD, are called HYPERBOLIC (or SADDLE). Points may also be called asymptotically stable (a.k.a. superstable).

Fixed Point (Transformation)

FIXED POINT (MAP)

Fixed Point Theorem

If g is a continuous function $g(x) \in [a, b]$ FOR ALL $x \in [a, b]$, then g has a FIXED POINT in $[a,\ b]$. This can be proven by noting that

$$g(a) \geq a \qquad g(b) \leq b$$

$$g(a) - a \geq 0 \qquad g(b) - b \leq 0.$$

Since g is continuous, the INTERMEDIATE VALUE THEOREM guarantees that there exists a $c \in [a, b]$ such that

$$g(c) - c = 0,$$

so there must exist a c such that

$$g(c) = c,$$

so there must exist a FIXED POINT $\in [a, b]$.

Flag

A collection of FACES of an n-D POLYTOPE or SIMPLICIAL COMPLEX, one of each DIMENSION 0, 1, ..., $n-1$, which all have a common nonempty INTERSECTION. In normal 3-D, the flag consists of a half-plane, its bounding RAY, and the RAY's endpoint.

Flag Manifold

For any SEQUENCE of INTEGERS $0 < n_1 < \ldots < n_k$, there is a flag manifold of type $(n_1,\ ...,\ n_k)$ which is the collection of ordered pairs of vector SUBSPACES of $\mathbb{R}^{n_k}(V_1,\ ...,\ V_k)$ with $\dim(V_i) = n_i$ and V_i a SUBSPACE of V_{i+1}. There are also COMPLEX flag manifolds with COMPLEX subspaces of $\mathbb{C}^{n_k}$ instead of REAL SUBSPACES of a REAL n_k-space.

These flag manifolds admit the structure of MANIFOLDS in a natural way and are used in the theory of LIE GROUPS.
